J. B.—A mirror or prism fitting is almost always used in studios of photo-engravers and the firms catering for them could easily supply you with one. You should apply for quotation to, say, Messrs. Penrose and Co., 109, Farringdon Road, London, E.C.1; or to Messrs. Hunters, Ltd., 16-18, St. Bride Street, London, E.C.4; or to any of the lens makers.

VENTO.—(1) The cost of registration is 5s., address Registrar of Business Names, 4, Clement's Inn, London, W.C.2. (2) Mr. John H. Gear, 8, Nottingham Terrace, Marylebone Road, London, N.W.1, is. Without claiming to be fully acquainted with the intricacies of the National Insurance Act we think an employee of the kind you mention certainly requires to be insured under the Act.

L. B.—It should not be difficult to colour the two parts of the lantern slide with dyes such as those you can conveniently buy in sets. They are put up by Johnson & Sons and the Vanguard Manufacturing Co., and are obtainable at any photographic dealers. If you don't want to do the colouring yourself you can easily send it to a trade firm, such as Messrs. E. B. Fry, 110, Pratt Street, London, N.W.1.

T. S.—Your proposed new position of the lamps seems to be about right, and the lanterns will do very well, though they would be better if D shaped instead of square. For children we should think it well to have at least three of the lamps to draw down to about 5 ft. from the floor. This will more than double their light-value as compared with the present position. We think that you will be quite safe in buying either of the lenses mentioned. The Aldis has the advantage of the soft focus if you care for it.

C. B.—(1) If it is only a slight scratch it has no detrimental effect whatever upon the portrait taken with the lens. (2) Probably there is no necessity for the lens to be repolished. (3) Although you say the lens consists of one glass, we think it consists of at least two glasses cemented together and indistinguishable from one glass unless you take the combination out of its metal mount and examine the edges. A lens consisting simply of one piece of glass does not form a satisfactory photographic objective unless stopped down to a very small aperture.

T. E. B.—There have been many processes suggested for conversion of a negative image into a positive (as in the Autochrome process) when using ordinary plates or bromide paper, but they are all rather complicated and somewhat uncertain. If you want to guarantee the completion of a result within a certain time, you had far better abandon the idea of using one of these methods and simply print from the wet negative, with interposition of a thin sheet of celluloid. Messrs. Rheinlander (New Malden, Surrey) make a specialty of celluloid of the required thickness for this purpose.

V. B.—Lead-lined tanks are used, but it is not the easiest thing to make them watertight, and if you are going to make the tanks yourself, and are fairly expert in woodworking, we recommend all-teak tanks. If the woodwork is really good, they are watertight, and require only very little caulking with red lead and linseed oil when putting together. But unless you can make them really well, we think it would be waste of time and money to do the work yourself. Excellent tanks, specially made and designed for quantity film work, are a specialty of Messrs. Otter-Judge and Co., 45-47, Rudyard Road, Hillsbro', Sheffield.

T. T. M.—The customer is quite within his rights in having even the first proof copied, and you are quite mistaken in thinking that the copyright becomes your property in consequence of his having done so. Inasmuch as he gave you the order to take the photographs, the copyright thereby became his, and it is not taken away from him by the fact that he has not paid for the sitting. Your remedy consists in suing him for the money, and in taking that course you are practically certain to obtain judgment against him in the County Court, since you can show that he has thought your work good enough to have copies made of it. If it was worth his while to do that, it is impossible for him to deny that the work was satisfactory.

W. J. B.—The buyers of such studies are chiefly agents for general advertisers, such as Bovril, Cadbury, and similar firms, and the publishers of calendars and photographs for the tops of chocolate boxes, etc. We give you the addresses of some firms who are agents for advertisers: Association of Designers, Ltd., 24, Devonshire Street, London, W.C.; Byron Studios, 8, Farringdon Avenue, London, E.C.4; Cambridge Literary and Art Agency, 8, Henrietta Street, London, W.C.; Carlton Studio, 30, Bedford Street, London, W.C.2; Francis and Mills, Granville House, Arundel Street, London, W.C.2; S. W. Partridge and Co., 21-22, Old Bailey, London, E.C.1; Rogers and Co., 22, Chancery Lane, London, E.C.4. As regards the calendar and box top people, the Rotary Photographic Co., West Drayton, Middlesex, is one of the largest producers. Very frequently in the calendar and box top trade studies are purchased in sets of six.

W. B. K.—The reflex type of camera is not suitable for wide-angle work, owing to the fact that space must be allowed for the swing of the mirror between the lens and the plate. Cameras have been made to get over this difficulty, but, generally speaking, the shortest focal length that can be used on the average quarter-plate reflex is about 5½ inches. There is no reflex which, in the quarter-plate size, will take such a short focus as 4 inches. If your intended branch of work is architectural interiors, you need not regret giving up the idea of a reflex, which is a very awkward instrument for interior work, where it has to be used on a tripod and often at a height which makes the viewing of the subject down the hood a very inconvenient operation.

W. B.—The most suitable focal length of lens for enlarging from half-plate negatives is about 9 ins. As regards the type, if you are enlarging by daylight, any objective which will cover a half-plate properly to the corners with be satisfactory for enlarging, so that the only question is the price that you are prepared to pay for the large aperture which will reduce the exposure. But if you are using artificial light, such as enclosed arc, it is not so easy, since many lenses, even high-class anastigmats, do not work correctly to focus when employed with an arc light. Generally speaking an ordinary R.R. lens, or one of the old more rapid euryscopes, is better for this purpose than many anastigmats, but you should get one or two on approval, and try them.

F. A.—You certainly cannot copyright a name for business purposes, and we do not think you can register such a name. What you can register is a name or mark to apply to particular goods made by you, or specially issued by you. A circular of information respecting such registration is obtainable from the Registrar of Trade Marks, 25, Southampton Buildings, London, W.C.2. If you employ a fancy name, such as either of those you mention, for the purposes of your trade, you are required by the Business Names Act to register the name, but that registration does not carry with it any exclusive right in the trade names which you adopt. Another firm might be using them elsewhere. If the same names were used by an immediate competitor you would no doubt have a remedy under common law, that is to say apart from any registration of a trade mark.

H. G.—(1) Personally we should think a 12-inch lens a very awkward and inconvenient choice for a quarter-plate reflex. There would be so many subjects, at any rate, such as we should want to photograph, for which such a lens would cover much too narrow an angle. It would mean that you could only deal with subjects for which you could take a distant view-point. We understand that this is what you want for the sake of the more natural perspective, inasmuch as the perspective depends solely upon the view-point, and has nothing whatever to do with the focal length of the lens, which latter simply determines the scale or size of the image. Even so we think 7½ inches is quite long enough for a quarter-plate camera. With a first-rate lens you should get all the facility you want as regards distant standpoints by contenting yourself with a smaller picture and corresponding enlargement of the negative. (2) We would infinitely prefer the quarter-plate "Soho," although it must be admitted that purely for portraiture the half-plate with a 17-inch lens would be a good outfit, although impossibly bulky and slow in use for outdoor work. Most people that we ever heard of have soon got disgusted with a half-plate reflex, and our own personal preference, after some wide experience of reflex cameras, is for the 3½ x 2½ size. We rather gather from your letter that you are laying unnecessary importance on getting a big picture on the negative. Possibly the people whose work you admire took smaller negatives than yours, but enlarged them considerably.

Contents.

SUMMARY.

In some notes on the portraits at the Royal Academy Mr. F. C. Tilney has some strong words for some of the ultra-modern styles. (P. 275.)

In the further portion of his article on the business relations between a photographer and his customer "Pelham Swinton" seeks to present to the reader's mind the sequence of events which in many instances has brought a sitter back to the studio dissatisfied with the proofs which have been submitted. Counselling an invariable soft answer, he turns to condemn the free sitting business. (P. 277.)

In a leading article we refer to the qualities of instant recognition of pose and lighting and of psychological sympathy which enter largely into successful portraiture to such an extent as to make or mar its success, even when everything is technically perfect. (P. 274.)

The factors which exposure and development constitute in the variations of the scale of tones in a photograph are the subject of a more than usually informative article in the "Photographic Journal of America." (P. 279.)

Some of the considerations which enter into the value of the good-will of a business are the subject of a note on page 274.

The report of the last meeting of the Edinburgh Society of Professional Photographers recounts the steps which are contemplated for extending the scope of the Society's work in conjunction with the Glasgow and West of Scotland Society of Professional Photographers. (P. 284.)

Prospectus and entry form of the forthcoming exhibition of the Royal Photographic Society are now obtainable from the Secretary, 35, Russell Square, London, W.C.1. (P. 273.)

In delivering the R.P.S. Hurter and Driffield Memorial lecture on Tuesday evening last Professor The Svedberg gave a very interesting account of the researches by which he has recently extended our knowledge of the action of light on the silver bromide grains of photographic emulsions. (P. 283.)

Process and apparatus for the electrolytic etching of half-tone plates are described in a recent patent specification. (P. 281.)

Arrangements have been made for the outing of the Affiliation of Photographic Societies to be held in the neighbourhood of Hitchin on May 27. (P. 286.)

Particulars of the quartz lenses advocated for their greater transparency are contained in a recent patent specification. (P. 281.)

At the Croydon Camera Club some striking firelight and moonlight effects were shown with coloured films, the commercial source of which is said to be unknown to either the lecturer or the audience. (P. 283.)

Steadiness in holding is an important item in the use of a vest-pocket camera, in regard to which we give a hint on page 274.

EX CATHEDRA.

The R.P.S. Exhibition. The Royal Photographic Society announces that its sixty-seventh annual exhibition will be held again at the Society's house, 35, Russell Square, London, W.C.1, from Monday, September 18, to Saturday, October 28. The selecting committee and judges in the pictorial section are Messrs. Marcus Adams, Bertram Cox, J. Dudley Johnston, Alexander Keighley, Herbert Lambert and Furley Lewis. Section II. of the exhibition is for pictorial work in lantern-slides and colour transparencies and prints, whilst the technical section is this year divided into seven sub-sections, each with its selecting committee and judges, devoted to natural history photography, photo-micrography, radiography, astronomical, aerial and spectroscopical photography, stereoscopic transparencies, technical colour photography and applications of photography. An entry fee of 3s. 6d. is charged, covering any permissible number of entries in all sections. The regulations as regards mounting, which have been adopted during the last few years, apply again to the pictorial section. Those entering lantern-slides are asked to send with them a short description of the subjects, for use on those evenings when the slides will be publicly shown on the screen, as will be done on one or more occasions during the period of the exhibition. It is announced that an improved method of showing colour transparencies and lantern-slides by electric light will be installed. The last day for the receipt of exhibits by carrier is August 25; or Saturday, August 26, from 10 a.m. to 6 p.m., if delivered by hand. The prospectus and entry form are now obtainable from the Secretary of the Society, Mr. H. H. Blacklock, 35, Russell Square, London, W.C.1.

* * *

Grain and Speed. The Hurter and Driffield Memorial lecture delivered on Tuesday last by Professor Svedberg was a highly interesting review of a branch of investigation which has been generously enriched by Professor Svedberg's own researches. His theme was the properties of the ultimate constituents of the dry-plate emulsion, the minute grains of silver bromide or iodide, as regards their exposure to light. How much do we know of the property which makes one grain differ from another grain in sensitiveness or of the mechanism of the change which renders a grain developable? Professor Svedberg answers: Very little, indeed, of what is still to be discovered; but his discourse made clear, even to the layman in this subject, the essentially separate aspects of the problem and the different methods of experiment by which the dry-plate may be made to yield the secret of its sensitiveness. One conclusion from the extraordinarily ingenious and difficult researches of Dr. Svedberg is of special interest. He sees nothing contradictory in the existence of ultra-minute grains (of silver bromide) of great sensitiveness;

or perhaps he may be more accurately quoted as saying that the emulsion maker has no need to regard growth in the size of the grain as an inevitable accompaniment of greater speed of an emulsion. The progress in the manufacture of plates within the last few years may be said to point to the same conclusion, greater and greater speed having been obtained without the coarsening of grain which years ago was often a concomitant of added speed. When Professor Svedberg refers to "grain" he is, of course, speaking of the silver halide particles in the film, so minute as to be invisible to the eye, not to the clumps and aggregations of these grains when developed, which constitute what a photographer calls "grain," meaning "graininess," to use the term coined by the Eastman Laboratory. Nevertheless, it can hardly be imagined that a finer initial structure of the sensitive material in a plate will be without benefit to the finished negative in this respect.

* * *

Holding Small Cameras. Apparently many beginners in photography who start with one of the folding vest-pocket cameras obtain negatives which are defective through blurred definition owing to unsteadiness of the camera at the instant of exposure. More care is, of course, required to hold such a small camera steady than is necessary for a heavier instrument, but we have noticed amateurs inviting failure by holding the camera in one hand and operating a flexible release with the other. It is much easier to obtain a steady position by holding the camera with both hands, using a finger of one to actuate a trigger release. Moreover, there is an advantage in many circumstances of following this practice, since in dull light the shutter may be worked at a much lower speed and more ample exposure thus given. For the very sharpest results, of which the lenses of these small cameras are capable, there is no better plan than to give the camera a really rigid support, as by holding it on the top of a fence or by pressing it sideways against a post. We could instance, as an example of the advantage of this method, the work of a notable exhibitor whose 10 x 8 and 12 x 10 prints from vest-pocket negatives might easily be mistaken for those from plates of these sizes exposed directly in the camera.

* * *

Goodwill. When portrait businesses are changing hands "goodwill" is an asset, the name of which is, perhaps, more frequently on the lips of the seller than those of the buyer, and, therefore, it may be of interest to quote a definition of goodwill recently given by a financial newspaper, viz., "the probability that old customers will continue their patronage of a concern or business despite change of ownership." According to such a definition goodwill largely represents reputation, and in a business, such as that of photographic portraiture, reputation is naturally bound up in considerable measure with the personal accomplishments of the head of the firm, usually the photographer himself. Inasmuch as in most cases his services disappear under a new proprietorship, it may be argued that in proportion as the work of a studio represents the individual ability, as shown in the portraits, of its former proprietor, the value of goodwill is correspondingly diminished. On the other hand, it must not be overlooked that the abilities of the photographer in the studio represent only a part of the reputation of the business; the printing, mounting and other departments contribute their share. Hence, it cannot reasonably be held that goodwill in such circumstances is a negligible asset, and in any case the reputation of a business obtained by fair and honourable dealing from the business standpoint over a course of years is unquestionably an asset of great value to a newcomer. Other factors likewise enter into goodwill, for example, the position of a place of business. If the circumstances of a lease make it necessary for removal within a short time after purchase, that fact would, of course, depreciate the value attaching to the goodwill of the business.

A POINT IN PORTRAITURE.

THE beginner in portrait work is often at a loss to understand wherein lies the difference between a good portrait and a bad one. As far as he can judge, his posing does not differ from that of more experienced workers; his lighting may be satisfactory and his technique good, yet his portraits are more or less failures from the customer's point of view, for although most average people have no artistic education they are not slow to appreciate a portrait which is pleasing and characteristic. We believe that the solution of the problem is near at hand when the operator realises that what are apparently trifling variations in handling the sitter are really of the greatest importance in determining the nature of the result. As in all other artistic work success in portraiture depends upon a rapid and accurate faculty of observation, which with some is inherent and in others can only be acquired by careful study. This is proved by the success of many women photographers who make excellent portraits with a modicum of practical knowledge, the well-known intuition of their sex serving to carry them through.

The margin between success and failure is such a narrow one that it may be overstepped a hundred times unconsciously. The situation may best be explained by comparing it with the practice of cookery; here, an excess of seasoning, a trifle too long or too short a time in the oven, a heavy hand in mixing or handling, and all the theoretical knowledge in the world goes for nothing. So it is with photography; one may study all the books on art or technique in existence without avail, if the eye is not quick enough to catch the right pose at the right moment. With the same arrangement of light and the same sitter a dozen operators will obtain a dozen different renderings, some of which will be vastly superior to the others.

The great point to be realised is the smallness of the variation in position or lighting which makes so great a difference in the picture and, when this has been done, to make sure of securing exactly what has been seen upon the plate. It must always be remembered that the living model cannot be treated in the same way as a sculptured bust. There is always a chance of a slight alteration in the pose, between the time of posing and the exposure of the plate, so that the operator must see that his picture is right at the moment of pressing the bulb. Sometimes a slight alteration of the position of the head may be necessary to secure a better contour, but then it requires care that the lighting is not thereby altered. It is surprising what a great change in lighting is effected by a slight turn of the head. Many writers on studio work have taken up the point of view that lighting is practically dependent upon the manipulation of blinds and curtains, but this is only true to a limited extent, as anyone may prove for himself by observing the effect of change of position only upon a sitter lighted by an ordinary window. Therefore, the quickest and most effective way of working is to get the desired lighting by movement of the sitter, and to take the camera into such a position as will enable the desired view of the face to be obtained.

It is not wise to rely too much upon the focussing screen as an aid to composition and lighting. The inverted position of the figure and the brilliancy of the coloured image upon the ground glass are misleading. It is better, therefore, to limit the ground glass to its original functions of placing the image properly upon the plate and securing good definition. Posing and lighting can better be done by direct observation of the sitter, but here is a trap for the unwary. A difference of only a foot or two between the point of view of the lens and the eye of the operator may have a very considerable effect upon the result, especially when the distance between lens and sitter is small. Not only should the two view-points be kept as close together as possible laterally but also vertically. From time to time attempts have been made to introduce twin lens cameras into the studio, but in no instance has the experiment been successful, for the reason already stated. If the lenses were side by side different views of the nose and the contour of the face were seen by the finder and taking lenses, while if placed one above the other, there was a variation in the renderings of the nose, chin and forehead.

The young operator, while studying the physical characteristics of the sitter must not neglect the psychological aspect; that is to say, an effort should be made to secure a portrait in which an animated and agreeable expression exists. This rendering of expression is one of the greatest characteristics of modern portraiture, especially in the case of men, and it is only obtainable by handling the mentality of the sitter in the same delicate way as is necessary with his features. To do this it is obviously necessary that the photographer should attain a certain degree of culture if he aspires to a good class of business. Every man or woman is most at ease with his or her own class. A sitter in the West End expects to find West End manners, and a Lancashire operative is uneasy if the operator cannot speak his dialect and understand his prejudices, as more than one London photographer who has migrated northwards has found to his cost. This knowledge is necessary to get the necessary delicacy of treatment in bringing out points of character. In dealing with the sitter's features quarter inches are of consequence. What a light touch must be necessary when any attempt is made to play upon the emotions?

PORTRAITURE AT THE ROYAL ACADEMY.

The exhibition at Burlington House is distinctly one that will be damned with faint praise. The Selecting Committee being, presumably, unable to find anything of outstanding merit upon which a sensation might be founded, have made up the deficiency with a few of the real modern shockers that one discovers in the galleries of certain dealers. And these horrors are largely in the department of portraiture. What the Dean and Chapter of this respectable old institution expect to gain by destroying their reputation for academicism and putting nothing in its place is a thing difficult to see.

One More of G.B.S.

Room XI. is a room of horrors, and so is one of the sculpture halls as far as some of the paintings that figure there are concerned. To a photographer seeking something in the way of example, thirsty for inspiration, and anxious to acquire the art-principles that lift portraiture above mere likeness-taking, there is nothing but outrage in such things as Max Martin's "Portrait Group" (634), with its sordid ugliness and black stripy shadows. "Viva" (639), by Augustus E. John, has the vulgarity of a washerwoman in a red jerkin. Fortunately, his "G. Bernard Shaw, Esq." (675) has merit. Its fearlessness reflects the mental fearlessness of the sitter. If one looks into this work, it reveals a deal of painstaking effort not generally supposed to be characteristic of this devil-may-care painter. But for all this, the photographer who knows what sculptors' "planes" are and what modelling is, will find Mr. Shaw's high brow strangely mis-shapen, as though it had been badly battered. He will also fail to find a spark of suggestion in the swipe and swirl which do duty for the sitter's clothing.

The chief value of the Academy show will be in the direction of occasional excellencies such as Harold Knight's two works, which are replete with the qualities that "modernists" try to arrive at by the path of lawlessness and extravagance. Mr. Knight's "Miriam" (617) is not only sound painting and draughtsmanship, it has character, life and beauty, with colour daring and intense enough to meet any requirement. It is the saving grace of Room XI. His "Head of a Girl" (240) is even finer, though less arresting. The youth and charm of the sitter is fully expressed; and in artistic arrangement, lighting, colour and feeling it is worthy to rank beside the old masters, the works of whom it would, by its modern vision surpass in realisation.

Decorativeness Overcomes Psychology.

The advantages which colour gives to the painter lead him to exploit his resources in half-length and full-length poses, and in this respect photography necessarily differs from painting by relying more upon the psychological content of heads only. The rich who commission portraits by painters want something fine and large; and you cannot make a very large thing of a head alone, therefore we see much ingenuity displayed by painters in designing their subjects, relying here upon elaborate costume or official robes, and there upon backgrounds and settings that shall be pictorial in themselves. The two portraits of "The Countess of Rocksavage," by Sargent (17) and Sims (177) respectively, reveal this effort. The first shows the lady in a historical costume, the other dispenses with costume as far as possible, and places the sitter and her son, also scantily clothed, before the pier between two arches of a loggia—a design of pronounced symmetry. Maurice Greiffenhagen's "Miss Janet Frizell" (25) is an arrangement of riotous and rich colour, supplied by the check jacket, bare legs, tow-selled red hair and flowered background, the whole thing being gorgeously decorative in its antique Italian frame, which must be several centuries old. The same painter's "Mrs. Jack Pettigrew" (115) is a head and shoulders of deep tone before an orange background, which relieves a fine "pattern"—a very distinguished work. A. Stuart Hill avails himself of the light tone of an old print of Worcester Cathedral on the wall to relieve the contours of the ex-Mayor of the town (135). Perhaps the most masterly use of academic robes in supplying decorative subject-matter is seen in Sir Wm. Orpen's "Sir Charles Villiers Stanford" (173), who is certainly looking picturesque beyond his wont. John M. Aiken adopts pure genre in "White to move and mate in three" (295). It is a beautifully painted portrait of a man looking down upon a chess board. Another idea by Ed. Brock is quite effective. His "Mrs. Eric Rose" (277) is in buff-coloured costume and wide-brimmed hat flooded with light and seated at full face. The background is of the "landscape" variety

à la Reynolds, only it is here given solidly as a dark wood with considerable realisation. Another of these fierce colour-contrasts has been employed by F. G. Swaish in his very striking "Mrs. George Heming" (44). This time the figure in rich low tones stands before the drawn curtain of a sunlit window. It is all cleverly true; but to photographers it is an old resource.

S. J. Solomon is too mature for such tricks, but he has sent a delightful portrait of the genre style called "Waiting" (529), a pretty young girl sitting on the arm of a chair, dressed, in black, for outdoors. All the domestic surroundings are choicely represented with quality of tone and colour, and all in perfect keeping. "The Producer" (590) is another genre portrait, a full-length of Mr. Du Maurier standing on the stage before the airy and dark background of the empty auditorium, the footlights behind him. He raises his hand with a managerial bearing. The Hon. John Collier is the artist of this distinctly new and quite successful idea. What a change from this to the close view of a woman and a child in bed and asleep, which M. Mackinlay sends and calls "La Siesta" (561). A work of this kind cannot be intended for anything but portraiture, but the idea is positively uninspired and unlovely.

Double Lighting.

There is a rather remarkable coincidence in the fashion for effects got by placing the sitter between conflicting lights. The painters, no less than the photographers, seem to catch at it as the last straw of novelty in a stream of stale tricks. Sir Wm. Orpen exhibits its misfortunes in the passage of dark tone that disfigures the brow and central features of "E. A. Colquhoun, Esq." (211). When either side of a face is in the limelight this must inevitably happen. Is it beautiful? Does it give the sitter's mental and moral characteristics their best chance? Much the same idea exists in Sir William's "Barbara Trevor Williams" (34), where the warmth of the reflected light from the left gives to the lady's skin a leathery look that must do her an injustice. In "E. J. Spencer, Esq." (89) the artist goes to the opposite extreme of a full flat lighting à la Holbein, a resource serving the sitter but little better; it is, therefore, a matter of relief that we find the normal lighting of an ordinary room adopted in his presentation portrait of "The Rt. Hon. Lord Bearsted of Maidstone" (99). May it not be assumed that the excellent character in this work is in some measure, at least, a result of this more ingenuous treatment? One more example of the futility of "stunt" lighting in portraiture is seen in brilliant illumination from below of "Major E. S. Pilkington's" riding breeches (418), the most assertive spot in the picture by M. B. Copeland.

Style and Pose.

Side by side with efforts to escape from the safe road of convention in the matter of lighting are those to avoid the usual thing in the general management of the theme. Allusion has already been made to backgrounds and effects adopted with these motives; but more striking still are the methods to get new ideas into the sitter's pose. The cases already cited of the genre motive are exercises in a direction which is legitimate and infinite, but unfortunately for novelty seekers, it is not new. Neither is the good old grand style which, if it lent some pomposity to a distinguished sitter, at least produced a work that was monumental in content. Such is the very commanding portrait by the veteran, Sir Arthur S. Cope, of "Field-Marshal H.R.H. the Duke of Connaught and Strathearn, K.G., K.T., K.P., etc.," who looks all these initials and much more, as he should. The grandiose air, the expansive pose, the full regimentals, the due swagger of ceremony are essential and valuable points. To turn from this good old-fashioned style to the new whim of Maurice Greiffenhagen in his "Sir Harry Gibson" (260) is to sigh for the old régime indeed. Sir Harry is in full military rig, and wears all his medals, but so far from looking what he should, he looks as though he had been pushed into a low, springy chair, where he has remained "all of a heap" and encumbered in an undignified way by his cocked and gold-laced hat and his gleaming sword of ceremony. His face expresses no more fine feeling than the circumstance would occasion. The painter has given to this picture, as likewise to "Major Frank Beattie" (231), the same opacity of black shadow, the same hot and deep scheme of colour, which mummifies the complexions, the same vacant wooden expressions. In the second example the soldier certainly does stand, but with no military air. The idea seems to have been to make these two gentlemen as much unlike soldiers as possible.

Charles Sims, on the other hand, was obviously determined to make "Sir Harry Frankland Hepburn" (224) look every inch the smart, well-groomed gentleman, and he has succeeded in achieving the outward signs of aristocracy in this ruddy-faced young-elderly man with white hair, grey moustache, society smile, easy but masterful pose, yellow gloves, stick, and not a speck upon his immaculate clothes. There is in the handling of this work, however, a technical shortcoming in the management of edges, the touchstone of good painting. Sir Charles Sims's soft and melting touch, so charming in the fanciful subjects he used to give us, seems unable to deal with the contours that cannot be baulked or faked in forcible portraiture. One feels that one could cut one's fingers on the knife-edge of "Mrs. H. B. Johnstone's" shoulders (264), and the neck of "Miss Monica Belfield" (10) is similarly edgy.

G. Hall Neale has made his portrait of "Chas Goddard, Esq." (343), irresistibly comic by an expression of doubt and apprehension with regard to the artist. The old gentleman's eye is keenly on the watch, and his hands on the arms of the chair ready to spring up at the first sign of any "larks." Is not such an effect one to be avoided at all costs in portraiture, as much as that of sleepy depression and mournfulness in Glyn Philpot's "Sisters of the Artist" (145)?

Psychology.

Of portraits which do wrestle with the personality of sitters rather than with their clothes and still-life effects there are several that will repay a photographer's study. And perhaps the most psychological is W. W. Russell's "Mrs. Walter Russell" (380), with her introspective look and listless hands. Another good example is S. J. Solomon's "Maurice Moscovitch" (297), a sound, life-like and interesting portrait.

The visitor will note the unnatural look of several portraits painted just a little below life-scale. It is not necessary to name them, as their littleness distinguishes them. In these spacious galleries the heads that are a little larger than life look right.

Groups.

What is said to be the year's sensation is Sargent's group, "Some General Officers of the Great War" (121). Imagine the task of managing twenty-two full-length figures, each of whom have equal claims to be adequately represented! And all in khaki! Of course, they had to be as nearly as possible in one line. The skill with which this appalling task has been carried through is worthy of Sargent's reputation. It is not the jumpy affair that Herkomer would probably have given us, but a quiet set of portraits in a gentle harmony that will do no harm to the works of the National Portrait Gallery, where it is to hang. Of other groups, the most successful, new and pleasing is that by George Harcourt, "Three Sisters" (158). One of these ladies reads a paper with outstretched arms and has her back to us, another stands at profile, and the third at full face; but they are all close together. It is all very cleverly managed. If the crowd in Richard Jack's "Marriage of H.R.H. Mary and Viscount Lascelles" (88) did not show an occasional profile, all but the officiating bishop in this monstrous futility would be portraits of back views: a rare piece of monumental historical painting to go down to posterity!

F. C. Tilney.

THE BUSINESS SIDE OF PROFESSIONAL PHOTOGRAPHY.

II. *(continued.)*—THE PHOTOGRAPHER AND HIS CLIENT.

Beyond this factor of artistic atmosphere, the handling of the customer by a photographer should follow the same rules as those of any average retailer. Firstly, the customer must, of course, be led to understand that his or her custom is valued and appreciated. This is at least one duty in which the photographer may engage with all the enthusiasm begotten by truth. He may not, on the other hand, experience the same conviction regarding the customer's opinions of his portraiture. And here is the most painful subject of all. A customer enters with her proofs, opens the wrapper, and throws them on the receptionist's table, exclaiming, "These are dreadful! Simply appalling! My friends didn't know me! They are *most* inartistic!" (referring, of course, to the proofs, not the friends). Now, if the photographer be standing by, or if the receptionist convey these remarks to him, his first feelings will be those of anger and resentment. In his opinion, the likeness is perfectly good; and he knows that there is certainly no cause for complaint as regards the artistic qualities of the photographs. On the contrary, he had taken more than usual trouble with this sitter, and he had achieved a pictorial result with which he was justly pleased. His first instinct, therefore, is to step forward, and to give a staunch denial to the lady's calumnies. If he is unwise, and his skin is yet untoughened, he will fall to the temptation, and the result will be an undignified argument, and a lost customer.

Now, let us follow the mental processes of such a customer, because it is only by understanding her psychology that we shall know how to deal with her, and ultimately to reduce her to amicability and reason.

The proofs arrive, perhaps, at breakfast time. The lady hands them to her husband for his opinion, and he, glancing from his morning paper, looks at them hurriedly. "They seem all right, my dear," he says, "but I don't like that dark shadow on the left side of your face." Then, having swallowed his last mouthful of coffee, he bolts for his 'bus or train. The proofs are now put aside for a few hours, and are forgotten, perhaps, until the afternoon, when a friend comes to call. "O, by the way, my dear," the lady exclaims, "I must show you the proofs of my photograph. They just arrived this morning. Now, what do you think of them?"

The friend looks at each carefully, and lays them down one by one. "I don't care for *that* one very much," she says, after a pause. "Your expression is better in this one; but what a pity your dress is so crumpled. Then, in *this* one, your hair isn't so nice. Where did you have them done?"

"At Jenkins and Son."

"O, Jenkins! Now, I wonder why these Jenkins people always make one's face look so dark on one side. I've noticed that in several of their photographs. I don't admire that sort of thing, do you?"

"I can't say I've noticed it," falters the lady. She is now somewhat disappointed, and is inclined to be annoyed, first with her friend, and then with the photographer.

Evening comes, and George drops in. George is the lady's brother-in-law. Moreover, he is an amateur photographer who develops his own films, and washes his prints in the bathroom basin.

"O, George, do give us your opinion on these. You understand these things. I'm sure I don't know what to think. Do you think they're at all like me?"

Now, I ask the reader, is there any erring human being capable of forgoing so glorious an opportunity as this? There is not. George, therefore, examines the prints critically, and pronounces them to be under-exposed, over-printed, over-exposed, under-developed, under-printed, over-developed, out of focus, too hard, too soft, or too flat, according to the extent of his photographic vocabulary. It is he, also, who first suggests the possibility of their being inartistic. The fire is laid, the tinder is dry, and this final remark sets the whole structure alight. "I believe you're right," exclaims the lady. "I think that dark shadow on the cheek *most* inartistic!"

At this point the husband inquires what is the price of the portraits. "Four guineas a dozen," says his wife.

"Four guineas a dozen!" exclaims the husband, who, unfortunately, is a commercial person, and does not appreciate the value of Art. "They're not worth more than four shillings!" George, who knows the retail price of self-toning paper, corroborates this opinion. "Just you take these back to Mr. Jenkins to-morrow, Margaret, and tell him from me that he'd better produce something a great deal better of you than that, if he is to get four guineas for them!"

Thus, by a steady process of inflammation, the poor lady arrives at the studio in a mental condition composed of disappointment 50 per cent., impatience 30 per cent., and mistrust 20 per cent. Instead of arguing with his customer, therefore, the photographer must bottle up any feelings of indignation which may arise, and set out to dissolve these psychological constituents. He should say something like this:

"I'm sorry to hear you don't like the proofs, Mrs. Brown. What is it you don't care for?"

"O—it's the expression, Mr. Jenkins. People say they aren't a bit like me. And my dress isn't at all nice in this one, and I don't like that dark shadow on the . . . ."

Mr. Jenkins gently interrupts her. He has heard all this before, and knows how to deal with it. "I'm very sorry indeed, Mrs. Brown. Of course, we must please you. Let me take one or two more negatives of you. I quite see what you wish, and I know now what to avoid. I should suggest also that these new ones be taken with a light background, which will obviate the heavy shadows of which you complain. Now, I wonder what day would suit you. . . . ."

The lady is now quite mollified. Her feelings of disappointment have gone; her impatience vanishes at the possibility of a further sitting as soon as she wishes; and her faith is restored. She makes an appointment, and leaves the room apologising to Mr. Jenkins for giving him so much trouble. He, of course, assures her that it is no trouble, and that he makes a point always of satisfying his clients. And here the story ends—except that, in nine cases out of ten, the lady orders from the first proofs after all.

This, of course, is only one instance; but similar treatment can be applied in most other cases. I can hear a photographer say, "Yes, that is all very well, but, after all, the first proofs were perfectly good. Why should I be obliged to suffer this extra expense merely because of a customer's ignorance? I would rather lose such a customer than submit to injustice of this kind!"

My dear sir, you are a fool; firstly, because you do not realise that you are conducting business in an unjust world, and secondly, because you do not realise the first principles of conducting business. It must never be forgotten that justice, being one of the higher ideals, is correspondingly expensive, and that even in this, our own country—peopled

with all the teeming millions of persons who never will be slaves—the price of justice is always measured by law-court expenses. And no one who is not a lunatic, or a gentleman of unlimited means, will ever contemplate so ruinous a purchase. Secondly, have you ever considered the financial loss to your business which may be caused by one dissatisfied customer? Have you ever heard gentle ladies discussing the merits and demerits of their respective drapers, grocers, and butchers? If you have never experienced this gratification, arrange to be present on the next occasion on which your wife has friends to tea, and listen with horror to the utter defamation of quite respectable firms, and watch how the most costly reputations are made gradually to fade away before the eyes of all present. It is necessary only to transpose, in your imagination, the name of your own firm for one of these, and turn pale.

The same rules apply, of course, to the answering of correspondence. When a customer sends a letter not entirely in accordance with the best aspirations of well-bred people—as customers have been known to do—one's first temptation is to answer it in a not unsimilar manner. If the recipient is a person of tender susceptibilities, he will not be able to overcome this temptation, and he will reply accordingly. By all means, let him reply, and as vindictively as his powers of composition will allow; but let him not post the letter until the following day. He will then put it in the waste-paper basket, and write something sensible instead.

This unfailing use of the gentle answer to turn away wrath is not only a good moral precept, but an excellent business proposition—and one which may cause many a photographer to see something in Christianity after all.

Now, the photographer may have successfully gauged the taste of his public, procured suitable specimens, displayed them in tasteful show-cases, and achieved an atmosphere of Art. All this he may have done, and done wisely; but now he feels that the public are not patronising him in such numbers as he thinks right. He becomes impatient, and one day the thought occurs to him that if only he could find some means of enticing the public into his studio more rapidly than by the usual methods he would enlarge his *clientele* by 100 or 200 per cent., and acquire, in a short time, a very comfortable income. The most obvious method of doing this is to invite people to be photographed. Why not? A carefully worded and flattering letter is all that is necessary, and any excuse—that their portrait is urgently required by the Press, or the absolute necessity of their photograph being secured in order to complete a collection of Solicitors, J.P.'s, M.P.'s, O.B.E.'s, Bank Clerks, Insurance Agents, or Country Squires—is easily arranged. A little such delicate flattery will be found to yield a ready response; and the letter should include the information that a set of proofs will be supplied, finished in an entirely new process, by which all necessity for touching, or retouching, or developing, or printing, is now happily dispensed with. This remark regarding the new process serves to pique the recipient's curiosity, while at the same time it extends to him the glittering possibility of obtaining a style of portrait which his friends have never seen. He is right. They will never have seen anything like it.

If the photographer is weak of mind, or deficient in ordinary business foresight, he may decide to adopt this policy. For a year or two he will do well; but after a certain period, when he has squeezed from the various societies, professions, associations, trades, and classes, all that is to be obtained therefrom, he will look round once more for the assistance of his ordinary legitimate business, and, behold! he will find this well-nigh vanished away. He has entirely forgotten that a large part of the successful conduct of his business depended upon the value which the private person placed upon his work. It was for this that he arranged all the attractive displays and the artistic atmosphere. But how can he expect the public to place value upon a commodity which he now gives away for nothing? It must be remembered that the public do not trust entirely to their own judgment. They see an article which pleases them, and they believe it to be good; but this opinion is not finally confirmed and sealed until they learn the price. If the price be a high one, they say: "O yes, I thought so. It's beautiful, isn't it?" But if the price be discovered to be lower than was anticipated, they immediately lower their estimate of the article. Even although a photograph please a person to the point of admiration—if he or she learns that the price is low, that admiration will drop to the level of the price.

What, then, is this photographer to do? If he has the courage to stop his free-sitting practices, he will do so, and gradually regain the respect of the public. But, if he has not, he must continue as he has begun, and endeavour by some means to extend his field of activity. It is for this reason that firms who practise this system to-day must always seek business far beyond the limits of the district in which they are situated. As this range is increased so does the cost increase, and, sooner or later, they are caught in the death-grip of the economic law of decreasing return. Those few who survive must sink to the level of commercial concerns producing a mere percentage on capital; and, as capital in a photographic business is—or should be—a small item, such firms must either swell their capital to an abnormal extent or become not worth the carrying on. A small free-sitting business is a contradiction in terms. Such a thing cannot exist.

The free-sitting system is like a drug; the more a man takes of it the more he must consume in order to live. It is at once an admission on the part of its devotee that his work is inferior to that of his rivals, and that he must find some other means of luring the public to buy it. It must be gratifying to the moralist to observe so great an evidence of this type of professional modesty in such a city as London, where photographers vie with one another in a self-depreciatory humility unparalleled in the history of commerce.

The free-sitting idea must not be confused with advertising. Advertising is a healthy science, and serves merely to draw attention to the commodity, and to create a desire for it. It does not throw it away. Nor must the offering of a free sitting be confounded with the practice of giving a free sample. A sample is always a very small portion of the actual commodity on sale; but the sitting is nine-tenths of the portrait. In it are contained all the photographer's skill, experience and personality.

Let not the aspiring photographer, therefore, be impatient. He has but three rules to follow: Supply the right kind of work, display it to advantage, and do all in his power to let the world know of it. To such an one will come reward in the fullness of time.

PELHAM SWINTON.

VALUE OF OLD PLATINUM PAPER.—"Most people know that platinum has gone up in price," writes a Lewisham correspondent, "but few may be aware of the extent of the increased value of the metal since pre-war days. During the annual domestic event known as spring cleaning some old platinum paper was discovered at the back of a cupboard in my workroom, paper purchased between fifteen and twenty years ago, and not suitable for printing upon to-day. I wrote to the Platinotype Company concerning it and the chance of getting some residue from it, and the company offered, and afterwards paid me, a little more for the old paper than I paid for it when new. This fact may be of interest to many of your readers."

EXPOSURE, DEVELOPMENT AND GRADATION OF TONES.

[Although the functions of exposure and development in modifying the scale of tone or contrast of the negative of a subject are fairly generally understood, there are perhaps many who have not made the matter as clear to themselves as is done in the following article by Mr. W. S. Davis in the "Photographic Journal of America."]

A KNOWLEDGE of how to secure with certainty a particular scale of tone is a most important asset to the photographer, since the successful representation of a subject—particularly the interpretation of some subtle quality of atmosphere or other delicate tonal effect—demands ability to work for a definite result.

Before intelligent control can be exercised it is necessary to understand both cause and effect, so the first point to consider is the factors involved.

The degree of contrast present in a subject is largely governed by the lighting, though the difference in tone and colour of individual parts, of course, contributes its share to the result. The *direction* from which the subject is lighted determines the *proportion* of light and shadow the subject-matter is capable of showing, but once the angle of illumination is fixed the *degree of contrast* presented varies with the *concentration* and *intensity* of the source of light. For these reasons one must not confuse flatness with softness, as the first is caused primarily by the subject being illuminated from an unsuitable direction, while the latter is brought about by diffusion of light coming from the proper source. To make this point perfectly clear, let the reader imagine himself studying under differing conditions an ordinary landscape comprising, as the principal features, a grassy foreground and group of good-sized trees in full foliage in the middle distance. With the sun back of the observer the entire scene will be flooded with light on a clear day, the amount of shadow being reduced to small areas among recessed parts of the foliage, and in consequence the general effect is that of flatness. Visit the locality when the sun is well to one side and a full play of light and shadow will be seen in the foliage, and any inequalities in surface of the foreground will appear in an attractive series of minor tone gradation. Again, view the scene when the sun is back of the trees and a still greater amount of shadow will be visible, since not only the side of the trees toward the spectator are in shadow, but long ones from the trees are cast upon the foreground. Repetition of these visits at the same hours on a day, when the intensity of the sunshine is reduced by the presence of a thin haze or mist, will reveal the fact that, while the general arrangement of light and shadow is the same as before, the scale of contrast is much shorter, due to the lighter tones being less brilliant and the shadows greyer in quality. The weaker the light becomes the greater the difference in this respect, until on a dull, cloudy day the illumination is so diffused as to cause well-defined gradations of light and shadow to disappear entirely. The same effects can be demonstrated indoors by posing a model or still-life group so that the light from a window strikes the subject from different directions; intensity of illumination being in this case altered by changing the distance between subject and window or covering the latter with semi-transparent material.

As so much depends upon proper illumination of a subject it is useless to expect modification of the purely photographic technique of exposure and development to overcome mistakes of lighting, but given an effect which looks agreeable to the eye, and there is no question that the amount of contrast shown in the finished photograph can be varied to a wide degree by straight methods of manipulation—the tone-scale being shortened or lengthened according to taste.

The length of the exposure and duration of development are the two most important factors in determining the general range of contrast shown in the negative, though in practice the nature of the sensitive emulsion, action of different light-filters, and changes in composition of the developer influence the result, but when using any selected combination of plate, filter and developer, the fact remains that the governing factors are exposure and development.

The length of the exposure determines the manner in which the proportional steps of tone are recorded, setting aside for the moment discrepancies due to unequal sensitiveness of the emulsion to different colours of the same tonal value. Theoretically correct exposure is that which reproduces accurately upon the film the relative position of each tone as it exists in the subject. Under- or over-exposure causes an unequal rendition of the tone-scale, the first sharpening contrast at the lighter end combined with failure to show differences of tonality in the shadows, while the second reduces the separation between each tone in the entire scale, thus shortening the range of contrast; this effect being most marked in the lighter passages.

The action of any developer is to build up contrast as its action is prolonged; hence it follows that stopping development at an early stage produces a flat image, which, be it noted, may appear very thin or decidedly dense according to the amount of exposure the negative has received, for which reason it is a mistake to judge the printing quality wholly by the degree of opacity. While prolonging the time of development increases the scale of contrast up to a certain point, the limit is reached when the highest light in the subject becomes opaque. If development is continued beyond this stage, the next lighter tones will one after another become opaque, thus destroying the steps of gradation at the lighter end of the scale, and to this extent lessening the number of those remaining.

From the practical point of view the only tone gradations of value in a negative are those which can be reproduced in inverse ratio by the printing medium employed to produce the finished picture; consequently, it is proper to point out the fact that a print on paper cannot show as long an actual scale of tone which it is possible to record in a negative, for the reason that a transparent image, viewed by strong transmitted light, represents between the extremes of complete transparency and absolute opacity a greater degree of contrast than that presented by pure white and black upon paper, as the latter is, of necessity, seen only by the light reflected from the surface. For this reason it is necessary to keep the range of gradation in the negative within the limitation of the printing-medium to reproduce, which varies considerably with the process used. Bromide paper or the carbon process, for example, will render a longer scale of tones than the harder-working slow "gaslight" or developing-out papers.

In addition to the cumulative effect of time development upon contrast, further control is obtainable by changing the composition of the developing solution. The developing agents in common use may be roughly divided into two classes: those which bring out detail all over before sufficient printing strength is reached in the negative, and the kind which build up opacity simultaneously with the appearance of gradation. The first, of which pyro is a typical example, are often known as high-factor developers because in timing development by the factorial method the time of appearance of the high-lights must be multiplied to a greater extent to arrive at the total time the developer should be allowed to act than is the case

with agents in the second class, like hydroquinone, which possesses a low factor. Pyro stands by itself, as it possesses the properties of both classes, requiring a high factor when used in weak solution without bromide, while the reverse is true when the solution is concentrated and a considerable amount of bromide is added. Obviously, it is an advantage to employ a developer of the first class when a soft negative is wanted, especially when the subject possesses an excessive amount of contrast, since the ability to bring out detail in the shadows before full printing strength is reached allows one to stop the action at the desired stage without needless sacrifice of gradation in any part. Dilution of a developer also seems to assist in securing greater softness, as it allows ample time for even action to take place, but it should be understood that dilution, or the selection of a high-factor agent, simply retards the building up of contrast; the result if pushed to the limit being similar to what is obtained with a low factor one, but it is of course necessary to develop to the limit. Increasing the normal amount of alkali, sodium or potassium carbonate tends to bring out detail proportionately quicker than opacity, but with extremely sensitive emulsions is liable to produce chemical fog. Potassium bromide should be omitted when the maximum amount of softness is wanted, or if its employment is absolutely needful to prevent the appearance of chemical fog in the brand of plate used, the amount should be reduced to the minimum.

The addition of a considerable amount of bromide before development is begun retards the first appearance of the image, and if development is continued a sufficient length of time increases the amount of contrast obtainable, but the greatest amount of control in this respect is secured by using such an agent as hydroquinone or pyro in strong solution, to which is added about one-fourth the amount of bromide as the weight of developing agent employed. The time of appearance is by this means much retarded, especially in the shadow portions of the subject; the opacity of the lighter tones building up slowly, but steadily, and if these appear to be gaining too much in proportion to the shadows, the partly developed negative can be transferred to a normal solution for finishing.

So far the element of colour in the subject has not been dealt with, but as the majority of views exhibit colours to which the emulsion reacts in a different manner than their visual appearance might lead the uninitiated to suppose, it is necessary either to make allowance for their unequal actinic action or take means for overcoming it. As every camera user soon finds out, blue and violet exert also as powerful an action upon a plain bromide of silver emulsion as white, being far more actinic than other colours of the same tone. Even colour-sensitised plates are not free from this defect, but there is this important difference, the latter possess increased sensitiveness to yellow, light orange and yellow-green, in the case of an orthochromatised emulsion, and a panchromatic variety is even more sensitive to the colours just mentioned, besides possessing the ability to record deep orange and red. This being true, the only thing necessary for obtaining a balanced rendering of various colours is to retard the activity of the over-actinic ones, for which purpose a suitable colour screen or light-filter is used over, or behind the lens. A yellow filter serves the purpose by converting the visual tint of blue to the less active green, and violet to a grey tone. The degree of correction obtained depends upon the depth of yellow and its spectroscopic quality, some shades being far more suitable than others, which is sufficient reason for purchasing filters only from reliable makers.

In practice, the advanced worker can make good use of several filters, ranging from a pale to a deep yellow, the first being used when but partial correction is desired, or only a limited increase in exposure is allowable, while the deepest is reserved for full, or even over, correction of the blue. A deep light-filter is at times helpful in controlling contrast when, as is quite often the case, the greater portion of the light tones are of a blue or violet tint, since retarding the action of these is then equivalent to shortening the photographic scale of contrast. The same means may be employed to deepen the tone, and clear up detail, in a distance obscured by blue haze. When, however, it is desired to accent the over-actinic colours, as for instance to exaggerate the effect of slight mistiness in distant parts of a landscape, a filter should not be used.

To sum up the foregoing observations, a normal result may be defined as one arrived at by timing the exposure to just record the deepest tone present in the subject by the time the high-lights in the negative have reached correct printing opacity in the course of development. Variations from the normal rendering may be obtained as follows:—

To increase contrast. Give the minimum exposure which will register the deepest visible tone and extend development beyond the normal time. If still more contrast is wanted, use a concentrated developer containing an extra amount of bromide, preferably choosing a low factor developing agent.

To especially emphasise the high-lights, while suppressing gradation in the shadows, slightly underexpose, and stop development as soon as the light and middle-tones attain printing strength, thus leaving the shadows very thin in the negative.

To reduce contrast, use a light-filter, when such will assist, as previously noted. Then if only a slight modification is needed, as in the case of a normally lighted subject, give full, but not over, exposure for the deepest parts and shorten the usual period of development. If more reduction of contrast is desired, use a dilute developer made up with a high factor agent and omit bromide. If still more softness of effect is called for, as in a harshly lighted subject showing very excessive contrasts, give several times the normal amount of exposure and develop to suit the lighter tones. By increasing exposure and reducing the length of development a good deal of control can be exercised, but the rendering of the relative intensity of the tones will not be literally true to the subject, though from a pictorial viewpoint the effect may sometimes be better, notwithstanding.

WILLIAM S. DAVIS.

FORTHCOMING EXHIBITIONS.

April 22 to May 27.—Royal Photographic Society. Colonial prints arranged by "The Amateur Photographer and Photography." Open daily from 11 to 5 p.m. 35, Russell Square, London, W.C.1.

June 1 to 30.—Royal Photographic Society. Prints by Pirie MacDonald, of New York.

August 26 to September 9.—Toronto Camera Club. Latest date for entries, July 22. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society 35, Russell Square, London, W.C.1.

Photo-Mechanical Notes.

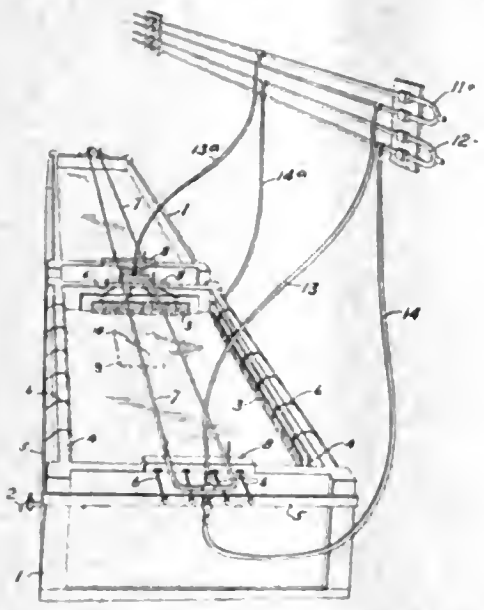
Electrolytic Etching.

According to a patent specification (No. 176,412) communicated by W. J. Mellersh-Jackson for The Weeks Photo-Engraving Co., 923, Sansom Street, Philadelphia, United States, the printed and burnt-in metal plate is subjected to the action of an electric current in a bath of electrolyte, consisting of a solution of sodium chloride to which a chloride of iron is added.

If desired, an acid, as well as a chloride of iron, may be added to the bath, and further, in some cases, depending on the nature of the metal and the electrolyte used, it may be advisable to immerse the plate in a hardening solution.

The electrical etching may be carried out in an apparatus such as that shown in the drawing.

In this drawing the numeral 1 designates the tank, which may be of any suitable waterproof and electrical insulating material, such as wood coated on the inside with an insulating, waterproof, and chemical resisting material. 2 is a drain cock for draining the tank for renewing the electrolyte or for repairs. Supported on frames 4 along the four sides of the tank are several cathodes 3 of any suitable conducting material, but preferably of carbon, which cathodes are electrically connected to a conductor or bus bar 5 by means of flexible conductors 6. The bus bar 5



extends around the tank near the top thereof so as to afford the shortest possible connections between the cathodes and the bus bar.

7 is a plate support, of conducting material, which is supported on blocks or strips 8 of non-conducting material on the ends of the tank 1, and 9 is a plate to be etched, which is suspended in the electrolyte from the plate support by means of a conductor 10. 11 and 12 are looped bus bars running parallel with a tank or series of tanks, and which are connected to the positive and negative poles respectively, of a suitable source of electricity. These bus bars 11 and 12 are connected to conductors 7 and the bus bars 5 of the different tanks by means of insulated conductors 13, 13a and 14, 14a, respectively.

As a low voltage current is usually employed in apparatus of this kind, and as an even distribution of the volume is essential, one of the legs of the looped bus bar 11 is connected to the conductor or support 7 at one end of the apparatus, and the support 7 connected at the other end of the apparatus to the other leg of the looped bus bar 11. The connections between the looped bus bar 12 and the cathode bus bar 5 is made in the same manner as the connections between the conductor or plate support 7, so as to provide an even distribution of the current throughout the tank, and avoid any difference of potential at the different points of connection.

As an electrolyte sodium chloride in water is used to a strength testing from 5 Baumé (heavy hydrometer) to saturation, to which is added from 5 per cent. to 10 per cent. of the volume of the former, of a solution of perchloride of iron of about 40 deg., or chloride of iron of equivalent strength, or the equivalent in dry chloride of iron, with or without the addition of nitric, hydrochloric, chromic, citric, or acetic acid, or any other suitable acid.

These acids increase the conductivity of the solution, which also varies with the strength of chloride solution. The acids also serve to keep the face of the anode clean.

In carrying out the invention the metal plate is first coated with a film which is sensitive to light. The film is then photographed, after which it is developed and thoroughly washed and dried. In some cases, owing to the character of the metal and the electrolyte to be subsequently used, it is advisable to immerse the washed plate in a hardening solution.

After the plate and film have been thoroughly dried, the plate is heated to a sufficiently high temperature to bake or enamel the photographed image on the metal plate. The back of the plate is then coated with an insulating material, and the plate is then placed in the electrolyte in the etching tank 1 and suspended in a horizontal manner as indicated at 9 from the conductor or support 7 by means of the conductor 10.

The plate is then etched by passing current through it as from the anode to the cathodes through the electrolyte so as to carry away metal from the plate. After the current has passed through the plate or plates, a sufficient length of time, the plate is removed and a proof is made, and if it is found that the plate has not been etched sufficiently, the proofing ink can be cleaned from the plate and the plate can then be further etched electrically or by hand.

As the image has been enamelled or baked on the metal, the image will not be affected by either the electrolyte, ink, ink-removing fluids, or the fluid used in the hand etching, so that the image is maintained in a perfect condition throughout the entire process of making the etched plate.

In some cases it is desirable, after the initial electrical etching, or after the first bite, to stop out the further etching of some portions and further etch other portions. This can also be done on plates made by the process by covering the portions to be stopped with shellac dissolved in alcohol or other suitable resistant material, which will prevent further etching of the covered portion, and after etching the covering can be removed without injury to the image.

Patent News.

Process patents—applications and specifications—are treated in "Photo Mechanical Notes."

Applications, April 24 to 29 :—

Films.—No. 11,473. Photographic films. J. E. Brandenberger.

Dark Slides.—No. 12,054. Photographic dark-slides. J. H. Campbell and J. Mackenzie.

Printing Apparatus.—No. 11,516. Apparatus for printing photographic papers from negatives. H. E. Jeffries.

Passe-Partout Bindings.—No. 11,713. Passe-partout edge bindings. I. Joseph.

Film Cartridges.—No. 11,699. Photographic film cartridges and protective leading strips or backings therefor. Kodak, Ltd.

Camera Stands.—No. 12,095. Camera stands. T. Peacock.

Daylight Development.—No. 11,520. Apparatus for daylight developing photographic roll films. J. Welch.

Aerial Cameras.—No. 12,018. Cameras for aerial, etc., photography. H. D. Watton.

Apparatus.—No. 11,679. Photographic apparatus. A. L. Waddell.

Stereoscopic Cinematography.—No. 11,960. Means for giving a stereoscopic effect to cinema pictures. M. Steinman Bezencenet.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Quartz Soft Focus Lenses.—No. 177,720 (April 21, 1921). The invention consists in providing in a photographic camera or projecting apparatus a lens of quartz interposed alone in the path

of the light-beam from the object to the image receiving surface, whereby photographic soft focus effects are produced.

It has been proposed to use a lens of fused quartz as a component of a compound objective, the object being to have the component lens of low refractive index and great durability, but the capability of a quartz lens alone by itself—that is not combined with other lenses—of producing soft-focus effects with rapidity of exposure, and the practical application of this capability to photographic and projecting apparatus, are the discovery and invention of the present inventor.

In the production of soft-focus effects advantage is taken of the wide range of rays transmitted by such a lens and the resulting light-dispersion; or, in other words, rays of different wave lengths in the beam are projected to correspondingly different foci. An uncorrected lens of quartz—particularly a lens of one unit only—because it does not bring light-rays of different wave lengths to a focus at the same point, greatly increases the chromatic diffusion as compared with a lens made of glass. This produces a sufficiency of definition without blurring and with that amount of softness which permits of broad modelling a result which can never be the product of microscopic definition.

Quartz also possesses the great advantage of transparency to the ultra-violet rays down to about 185 $\mu\mu$, whereas most varieties of glass absorb in large degree that part of the spectrum of shorter wave length than the visible violet rays, about 390 $\mu\mu$. These ultra-violet rays affect chemical reaction, particularly that produced by light on a photographic plate to a much greater extent than the rays of visible light, and, therefore, the quartz lens show a great increase in rapidity as compared with a lens made of any of the optical glasses in common use. Comparative tests prove that this rapidity—(that is, the speed with which the photographic plate is reacted upon)—reaches five times that of glass lenses used for similar photographic purposes. Because rays of great intensity are transmitted which do not pass through glass at all, it is possible to get photographs in comparatively dull daylight—such as that from windows in an ordinary room or in deeply shaded woods or forests—with a rapidity of one-sixteenth of a second.

It is preferred to make the quartz lens by grinding the material to meniscus form, and the material may be fused quartz which can now be produced for optical purposes free from strain. As compared with a similar lens of glass, the quartz lens exhibits a marked difference in the variation of focus between the visible image and the actinic image recorded on the plate. In the case of the glass lens, this difference amounts to as much as one-fortieth of the focal length. In the case of the quartz lens it is only about one-four-hundredth of the focal length. This is insufficient to make any real difference in focussing necessary.

In using the meniscus quartz lens in the camera, the convex surface should be turned toward the plate, the diaphragm should be well in advance of the lens, and a lens shade should be employed—especially if the lens is worked at full aperture.

As an example of one of the soft focus lenses described in the application, there is used in one instance a lens 2-in. diameter, radius of curvature of the concave surface $6\frac{1}{2}$ in.; radius of curvature of convex surface, $4\frac{1}{4}$ in.; lens 1·5 in. thick at edge, and placed $1\frac{5}{8}$ in. behind the iris diaphragm which has a maximum opening of $1\frac{1}{2}$ in.—W. J. Mellersh-Jackson, 28, Southampton Buildings, London, W.C.2, for Hanovia Chemical and Manufacturing Co., Chestnut Street and New Jersey Railroad Avenue, Newark, United States.

The following complete specifications are open to public inspection before acceptance:—

Print-Out Papers.—No. 178,828. Photographic print-out papers and prints made therefrom. J. A. Johnson.

Apparatus.—No. 178,853. Apparatus for coating with a protective layer photographic or like films. H. Lichte.

Reproducing Sound Waves.—No. 178,805. Process and means for the production of sound-wave photograms. R. Mylo.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

Weeks Electrical Etching (Design).—No. 420,180. Electrical etching machines. Weeks Photo-Engraving Co., Incorporated, 923, Sansom Street, Philadelphia, Pennsylvania, U.S.A., photo-engravers and manufacturers of electrical etching machinery.

Velox (Four Designs).—No. 421,045. Photographic papers. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials.

New Books.

The Barnet Book of Photography.—The instruction manual of Messrs. Elliott's was a work which passed through successive editions before the war and achieved wide popularity from the practical character of its contents and the attractive production of the book. In issuing, after unavoidable delay, a new edition, Messrs. Elliott have preserved these two features and have produced a handsome volume composed of a series of thirteen chapters by well-known photographic writers on various branches of photographic work. Mr. W. L. F. Wastell, who has edited the volume, leads off with a paper on negative making, dealing in a plain and straightforward manner with the development, fixing and after-treatment of plates in accordance with the current practice. Orthochromatic photography is in the hands of G. T. Harris, a reproduction of one of whose photographs is a particularly fine example of the skilful use of an orthochromatic plate. The printing processes occupy several chapters; gaslight by the late C. H. Hewitt; P.O.P. and self-toning by H. W. Bennett; bromide by C. W. Somerville; bromoil by J. A. Sinclair; lantern-slides by James Shaw and enlarging by F. J. Mortimer. What may be termed particular branches of photographic work are represented by articles on home portraiture by W. Harold House, architectural photography by Ernest Marriage, on high-speed photography by Adolphe Abrahams and on reflex cameras by G. E. Brown. The book is most attractively printed and bound and externally recommends itself to the amateur photographer, who will not be disappointed by the good fare within. The price of the new edition is 3s. net.

Eyes and Spectacles.—A translation of the work by Dr. M. von Rohr has been made by Mr. A. Harold Levy and published, price 6s. net, by the Hatton Press, 123, Fleet Street, London, E.C.4. Although written for the information of those engaged in visual optics, and particularly in the spectacle-making trade, the first chapter is an account of the properties of the eye in respect to vision, such as cannot be found expressed in a similarly precise and simple manner in the lesser optical text-books. For the sake of this chapter alone and its simple treatment of properties such as sharpness of vision, accommodation, perspective, and binocular vision, which have their application in the making of photographs, the volume thoroughly deserves a place in the library of those interested in photographic optics. Mr. Levy has not had the easiest task in making the translation, as those who have undertaken the work of translating Dr. von Rohr's highly condensed and idiomatic German will know, but with the assistance of the German author he has made what appears to be throughout an English rendering exceedingly close to the original.

Reports of Applied Chemistry.—The sixth volume of the series of reports on the progress of various branches of chemical industry, which is compiled each year by the Society of Chemical Industry, has again appeared under the editorship of Mr. T. F. Burton. It is published by the Society, 46-47, Finsbury Square, London, E.C.2, price 12s. 6d. Members of the Society obtain it for 7s. 6d. There is scarcely a branch of the chemical and metallurgical manufacturing trades, the progress of which during 1921 is not reviewed in these pages in the shape of a very readable report which draws together the threads of research and presents the advancements which have been made in a form in which a chemist whose specialty is in another field may readily appreciate them. Photographic materials and processes have formed a section of the work from its

nception. The report in the current volume is by Mr. F. F. Renwick and is a very able review of progress in invention and manufacture as disclosed by recent published literature and patent specifications.

PHOTOGRAPHY IN COLOURS.—As we go to press we have received a copy of the new edition of "Photography in Colours," by Dr. Lindsay Johnson, just issued, with revisions and additions, by Messrs. Routledge. The price is 7s. 6d net, not 6s. net as provisionally announced. A review of the work will appear in an early issue.

New Apparatus.

CORRUGATED ZINC.—Mr. A. E. Bawtree, 7, Manor Park Road Sutton, Surrey, sends us a specimen of the corrugated zinc grooving which he is placing on the market for use in the fitting of lantern-slide boxes, drying racks, plate washers, negative storage boxes and similar purposes. There is no doubt that there is a considerable demand for this material among photographers fitting up their own appliances of one kind or another. Mr. Bawtree supplies the zinc at the rate of 1d. per 5 grooves, carriage paid. Thus a strip of 50 grooves costs 10d.; it measures 10 ins. The grooving is 1¼ in. in width.

DESIGNATION MASKS.—Mr. A. W. Bowen, The Laurels, Arkley, Barnet, who for many years past has made a specialty of the supply of masks, title strips, etc., for use in printing from photographic negatives, sends us some samples of his latest masks, containing the photographer's name and address, for printing under the portrait at the same time as the picture itself. The lettering in these masks is now printed on coated celluloid instead of on a transferred gelatine film as formerly. Also the lettering itself is much improved, and can be supplied in various styles. Mr. Bowen has a wide range of sizes, and can, in fact, supply anything in the way of a mask, which the photographer may want for insertion of his name and address into portraits, view postcards, etc. In postcard size, for printing a title or name and address on a white border simultaneously with the picture, the price of the mask is 1s. 3d.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MAY 15.

Southampton C.C. "A Chat about Lenses." G. Chalk.

TUESDAY, MAY 16.

R.P.S. "Natural Colour Photography." J. F. Shepherd. A Demonstration of Fallowfield's "Translucent Screen" Outfit.
Bournemouth Camera Club. Photographic Jumble Sale.
Cambridge Phot. Club. "Photograms of the Year" originals.
Hackney P.S. Photographic Apparatus. A. Dordan Pyke.

WEDNESDAY, MAY 17.

Croydon Camera Club. "Shaw, Shakespeare and Cæsar." Cavendish Morton.
Dennistoun Amateur P.A. Impressions of Outing.
Rochdale Amateur P.S. "Experiment with Liver of Sulphur Toning." W. Lord.

THURSDAY, MAY 18.

Hammersmith Hampshire House P.S. "Iron Salts in Photography." G. Hawkings.

SATURDAY, MAY 20.

Bradford Phot. Soc. Outing to Bolton Abbey.
Edge Hill Camera Club. Outing—Halewood and Gateacre
Sheffield Phot. Soc. Outing to Rivelin Valley.
Southampton Camera Club. Outing to Ocknell Pond.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held on Tuesday, May 9 at the house of the Royal Society of Arts, Mr. W. L. F. Wastell, president, in the chair.

The third Hurter and Driffield memorial-lecture was delivered by Professor The Svedberg of Stockholm, who took for his subject "The Interpretation of Light Sensitivity in Photography."

He first briefly referred to the much discussed theme of recent photo-chemistry, viz., the validity of Einstein's law of the photochemical equivalent in cases of change in a substance by exposure to light. The experimental evidence was conflicting. Some reactions were in fair accordance with the law; in others the yield is greatly in excess of the theoretical. Secondary reactions appeared to provide the explanation.

Passing to the problem of an emulsion of silver bromide, Professor Svedberg distinguished between the sensitiveness of a plate, the sensitiveness of the individual grains of silver halide and the sensitiveness of the material of those grains. The first depended on the number of grains per unit area, their size and distribution and the sensitivity of the material composing them.

As regards sensitiveness of grains, the experimental evidence favoured the view that a grain was rendered completely developable or left undevelopable by exposure to light. But grain sensitiveness, so far as it possessed experimental significance, meant the percentage number of grains made developable by a certain exposure. It was an average, not a property of an individual grain. There was undoubtedly a relation between sensitiveness and size of grain—the larger grains being always more sensitive than the smaller ones—but later on in his lecture Professor Svedberg expressed the view that greater sensitiveness was compatible with a smaller size of grain.

How he asked, was it possible to account for the fact that there seemed no reason why a large grain was more sensitive than a smaller one, i.e., became developable by a lesser exposure? He had been able to throw some light on this subject by observing that development started at certain points within the grain. One such starting-point made a grain developable. The number of starting-points in a grain appeared to follow the laws of chance, and thus larger grains were (on the average) more sensitive than smaller ones, because of the greater probability of their containing one starting point or more than one. He had, moreover, found that the surface area, not the volume, is the measure of "size" which determines the percentage number of developable grains.

Passing from considerations of this kind, he defined the sensitiveness of the material (silver halide) of the grain as measured by the average number of developable centres per unit area of grain surface. In these terms the sensitiveness of the essential material of an emulsion could be expressed independently of the sizes of the grains. In emulsion making the aim was to get small grains of high sensitiveness, an aim which was not inconsistent with his researches.

Professor Svedberg's lecture was listened to with the greatest interest by an audience which should have been larger. On the proposition of Mr. W. B. Ferguson, K.C., seconded by Dr. T. Slater Price, the thanks of the Society were accorded to Dr. Svedberg, and a replica of the Hurter and Driffield medal presented to him as a memento of the occasion.

CROYDON CAMERA CLUB.

Richard was himself again in the person of Mr. A. Dordan Pyke with a lantern lecture on "Home Portraiture." His last failed to come up to his usual standard, from circumstances, it has now transpired, not under his control.

It is therefore a pleasure to record that Mr. Pyke last week scored well with an amusing and instructive theme. Tonic also, as opening up almost unlimited possibilities of varied work at home. Some realistic natural history studies, due to Mr. Wilkinson, came first, which even Mr. Martin Duncan might envy. These were followed by delightful portraits of children, and animal, insect and genre studies taken by Johnson's flashlight.

The flash proved to be quick enough to record no reflex movement, even of cats, in relation to rapidity of combustion. A spider, too, came out distinctly in all details, though no trace of the sitter could be found after the exposure. Luckily this was a free sitting.

An interesting point was incidentally raised by Mr. Pyke as to whether the spirits of deceased pets re-visit this mundane sphere. He was inclined to this opinion by being awakened one night by the singing (sic) of a cat whose voice strikingly resembled that of a departed pet. This he proceeded for hours, despite unappreciative remarks which fell from the window. Without wishing to cast doubts on the existence of spook cats, the only presumption

arising out of the incident appears to be that Mr. Pyke used language befitting the occasion.

"Table-top" photography, which brought the evening to a close, was excellent, especially those slides which included humorous and cleverly modelled plasticine figures by the lecturer's wife. Some of them fairly revived the jaded photographic appetite of the old stager. Mention should also be made of some effective "Celophane" coloured films for firelight and moonlight studies. No one, including the lecturer, knew where they are to be obtained.

In the discussion, Mr. Jobling, alluding to some striking views shown with natural clouds taken with a pale light-filter on Wellington's anti-screen plates, pointed out that without a filter they would always do more than an ordinary plate in the way of colour correction, and with a filter of light hue more than a yellow sensitive ortho' plate similarly screened, and with no sacrifice of speed. He had obtained a good representation of khaki on unscreened anti-screen plates. A hearty vote of thanks was accorded Mr. Pyke for a lecture which can confidently be recommended to photographic societies.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held on Monday, May 1. Present: Mrs. Mackay, Messrs. J. Campbell Harper, Norman Thomson, J. B. Johnston, Alex. Ayton, John Thomson, W. J. Hutcheson, Aikman, Fergusson, George Balmain, W. B. Hislop, Dakers, and E. D. Young. Mr. J. Campbell Harper, President, in the chair.

The Secretary read letters of resignation from the Society from Mr. William Halkett, Portobello, and Mr. Charles D. Crooke, Edinburgh, and these were accepted with regret.

The Treasurer submitted his accounts for the year 1921-22, from which it appeared that the balance at the credit of the Society amounted to £17 3s. 6d.

The accounts were gone over with the relative vouchers and approved and signed by the Chairman.

The election of office-bearers was then proceeded with. Mr. Hislop moved that Mr. J. Campbell Harper be re-appointed President for the next session. This was seconded by Mr. Fergusson, and cordially approved.

Mr. Campbell Harper, in returning thanks, said that he would do his best for the Society, and appreciated the confidence which the members reposed in him. Mr. George Balmain, Mr. Fergusson and Mr. Moffat were re-appointed members of the committee, and Mr. Fergusson moved that Mr. Norman Thomson be elected a members of committee in place of Mr. Coltart. This was seconded by Mr. E. D. Young. There being no other nominations, these gentlemen were appointed members of the committee. The President moved the re-election of Mr. A. Allan Lowson, Solicitor, Supreme Courts, as Secretary and Treasurer, which was unanimously agreed to.

Mr. E. D. Young moved that a cordial vote of thanks be given to Mr. George E. Brown, Editor of the "British Journal of Photography," for his kindness in publishing the minutes of the Society in his journal. This motion was heartily approved of, and the Secretary was directed to transmit to Mr. Brown an excerpt from this minute.

The Secretary read to the meeting Mr. W. B. Hislop's report on the photographic chemistry and optics class held last winter. Mr. Hislop stated that the attendance was excellent, and that the majority of the students showed a considerable amount of interest in the lectures, although the benefit they would derive therefrom was more in proportion to their previous education and training in photography. He thought the class was a success, but he was doubtful whether another year on the same lines would produce the same satisfactory results, as the effects of the class had been to increase the differences between the various grades of students. This was inevitable in a lecture course.

He suggested that if it could be arranged for the students to have some experimental work, it would enable the class to work on a more level footing, besides fixing the experiments in their minds. He also suggested if the students had the privilege of visiting three or four studios in town in order to become familiar with photographic appliances and lenses and their working, it would be of an immense advantage and an effective way of deepening their interest in their work. The President, on behalf of the members, thanked Mr. Hislop for his report, and assured him that there would be no difficulty in procuring apparatus for use of the students, and arranging for some studios in Edinburgh being opened to them. The President further stated that he could think of no one who was so eminently fitted to undertake the tuition of the class as Mr. Hislop, and hoped that he would agree to continue his good work for another year. Mr. Hislop, in reply, stated that he could not meantime agree to undertake the class for another year, but he was willing to afford his successor every assistance in his power. It was accordingly remitted to the President to call on Mr. McNally, of the Edinburgh Education Authority, and endeavour to come to some arrangement for the carrying on of the same.

Mr. E. D. Young, in moving that the constitution of the Society be altered, stated that the Society had been hampered from increasing its membership and extending its activities by the restricted area from which it could draw its members. He accordingly moved that the constitution of the Society be altered (1) by deleting in Rule 3 the words "in Edinburgh and District," and (2) by adding in Rule 7 after the words "First," "For members who carry on business within the City of Edinburgh, and for all other members 10s. 6d. per annum." This was seconded by Mr. Fergusson, and unanimously agreed to. Mr. Fergusson stated that in respect that the rules of the Society could only be altered at an annual general meeting in May, it was thought expedient, in view of the coming Congress and Fair, to have power to call an extraordinary general meeting of the Society for that purpose on the requisition of at least five members. He accordingly moved that in Rule 9 there be added after the words "general meeting" the words "or at an extraordinary general meeting of the Society for that purpose on the requisition of at least five members." This motion was seconded by Mr. George Balmain and unanimously approved.

The Secretary read to the meeting a postcard which had been handed to him by Mr. Hislop and Mr. Harold Hood, of Hood and Co., photo-engravers, Sandbride Works, Middlesbrough, requesting him to send a copy of the rules of the Edinburgh Society of Professional Photographers as they wish to form a similar society in that district. The President stated that it was very gratifying that similar societies to theirs were being started in other towns. The Secretary was instructed to send a copy of the rules, and to say that the President and members of committee would be pleased to afford them any assistance in the formation of their society.

The Secretary read a letter which he had received from the Secretary of the Glasgow and West of Scotland Society of Professional Photographers, dated April 7, giving their society's views that the formation of a Federation was, in their opinion, premature, and that in regard to the subject of the Congress they thought that the management and responsibility of it should be left entirely in the hands of the Edinburgh Society, although they would give the Congress their support. A map of Scotland was also enclosed suggesting that the country be divided between the two societies so that the Glasgow Society could solicit members from those on the west side of Scotland, and the Edinburgh Society from the east. In view of these findings the Glasgow Society did not consider it necessary for the proposed Conference to be held on April 21. The President stated that this letter had come to them somewhat in the nature of a surprise, as it was the impression of both Mr. Young and himself, who attended the Glasgow meeting on behalf of this Society, that the Glasgow Society were most anxious that the question of Federation should be proceeded with at once. He further stated that there were several questions which had been discussed with the Glasgow Committee, and which he had hoped to settle at a joint meeting,

These were (1) the drafting of a joint circular to be issued by both societies; (2) mutual agreement as to the boundaries; and (3) the question as to whether country members should have the option of joining either society. He had convened a meeting of the Committee to discuss the matter, and a reply was formulated to the Glasgow Society, in which it was stated that this Society had no desire to press the question of Federation immediately, but that the impression of Mr. Young and himself was that their Society wished that federation should precede that of the extension of the boundaries of the societies and the formation of societies in other towns. It was also pointed out that they had not replied to the above three questions which were under discussion at the meeting in Glasgow, and as the Edinburgh Society desired to act in unison with them it was suggested that a confe

ence be held to decide the questions. No reply had as yet been received to this letter.

The meeting thereafter considered the proposed division of the map, and after discussion came to the conclusion that the proposition was impracticable. It was felt that the question which society country members should join should be left entirely to themselves. Mr. J. B. Johnston accordingly moved that the proposed division line in regard to the allocation of towns be not agreed to, and that a friendly arrangement be come to with the Glasgow Society with regard to the issuing of circulars so as to avoid over-lapping. Mr. Hislop seconded the motion, and it was agreed to. The Secretary was requested to communicate this to the Secretary of the Glasgow Society.

The President read to the meeting a letter which he had received from Mr. Thomas Williamson, of the Edinburgh Exhibition Association, stating that the Association were erecting a large exhibition hall in Annandale Street, which he thought would be suitable for the Congress and Fair. The President reported that Mr. Young and he had an interview with Mr. Williamson, who stated that he could provide a lecture hall, exhibition hall, stalls for manufacturers and dealers, and also a band. His charge for stalls was 4s. 6d. per foot, including skeleton stand and roof. The hall would be lighted, but separate lighting would be provided at schedule rate. Mr. Williamson suggested that the best time of year for holding the Congress and Fair would be the last week in March. It was agreed that the Society should not commit itself in any way until it was ascertained how far the manufacturers and photographic dealers would support the exhibition by taking stalls. It was arranged to convene a meeting of the committee for Wednesday evening, the 10th inst., to frame a letter to the manufacturers and dealers inquiring if they would give their support to the proposed project.

Mr. Young intimated that he had written the board of directors of the College of Art asking for the use of their hall for an exhibition of American portraiture which was presently being exhibited in London. This was approved of by the Society. It was resolved to make every endeavour to secure the exhibition for Edinburgh for one week.

A hearty vote of thanks was moved to the President and members of committee and the Secretary for their services during the past year.

A vote of thanks to the Chairman concluded the business.

Commercial & Legal Intelligence.

Legal Notices.—Notice is given that general meetings of the members of the Precision Lens Moulding Co., Ltd. (in liquidation), the Crescent Lens Co., Ltd. (in liquidation), and the Guaranteed Lens Co., Ltd. (in liquidation) will be held on June 2, at 2-3, Duke Street, St. James', S.W.1, for the purpose of considering the liquidator's reports, showing the manner in which the windings-up have been conducted, and the properties of the companies disposed of.

Notice is given of the dissolution of the partnership between Edward Lincoln Airey and Leighton Airey, carrying on business as fine art dealers and picture-frame manufacturers at 11-13, Railway Road, Blackburn, and 10, Hargreaves Street, Burnley, under the style of Edward L. Airey & Son. All debts due to and owing by the late firm will be received and paid by Mr. E. L. Airey, who will continue to carry on the business at Blackburn under the same style.

NEW COMPANIES.

Photo. Printing Paper Co., Ltd. This private company was registered on May 1. Capital £500 in £1 shares. Objects: To acquire the business of drawing office stationers and printers carried on as the "Photo. Printing Paper Co.," by V. Niox, of 61, Marsham Street, Westminster, and to carry on the same and the business of photo. printers, mounters, lithographers, printers and dealers in sensitised papers and other materials, etc. The subscribers (each with one share) are: V. Niox, 61, Marsham Street, Westminster, S.W., photo. printer; L. Compender, 11, Ferndale Road, Clapham, S.W.4, book-keeper. V. Niox is permanent director and chairman. Remuneration: As fixed by the company.

Moons Stereoscopic Pictures, Ltd.—This private company was registered on May 1 with a capital of £12,500 in £1 shares. Objects: To acquire an invention in connection with concave screens and other means for taking and projecting a stereoscopically cinematograph picture, etc. The first directors are: S. H. Moon (managing director), 51, Park Road, Moseley, Birmingham; H. H. Moon, Bristol Road, Birmingham; J. Payton, 14, Lightwoods Hill, Warley, Birmingham; and E. S. Lermit, 34, Lightwoods Hill, Warley Birmingham. Qualification: 100 shares. Remuneration as fixed by the company. Registered office: 10 and 12, Holloway Road, Birmingham.

News and Notes.

The Club Photographer.—We understand that Dr. R. T. J. Glover has resigned from the technical editorship of the "Club Photographer," which he has held since the first issue of our Liverpool society contemporary.

A Photographic "Barrieism."—Sir J. M. Barrie said in his Rectorial Address at St. Andrews last Wednesday: "Don't put your photograph at all ages in your autobiography. Photographs give away what you have done with your life."

Films by Wireless.—That cinematograph pictures will be transmitted ere long by radio was declared to be probable by Mr. L. C. Porter, President of the Society of Motion Picture Engineers, in his address to the convention of that society at Boston, U.S.A.

The Art and Practice of Photography.—This excellent little manual by Mr. W. Bell, of the Criterion Co., which we reviewed some months ago, has now been issued in a second edition, which will be on sale at bookstalls, newsagents, and photographic dealers, price 6d. Anyone unable to obtain it from these sources may receive a copy by remitting 8d. in stamps to Messrs. Criterion, Ltd., Stechford, Birmingham.

Automatic Printing Exposure Timer.—In his "Paris Notes" a month or two ago M. Clerc referred to the very ingenious appliance of MM. Godefroy, of Paris, for automatically giving any particular exposure (and repeating this as often as required) in the use of a printing machine or in fact of any electric light. The appliance is now obtainable in this country from the Anglo-French Photography Co., 49, New Kent Road, London, S.E.1, who supply it, delivered free in the United Kingdom at the price of £4 10s.

Mr. Robert Ballantine, 103½, St. Vincent Street, Glasgow, sends us a 40 page price list of secondhand photographic apparatus and general sundries, in issuing which he makes special mention of the fact that every item has been purchased, tested, and examined by him personally, and that, therefore, he can give his personal guarantee of the satisfactory working condition of the goods. The price list specifies a large number of hand and stand cameras, lenses and enlargers, and is obtainable free on addressing a postcard.

Albumen Paper.—A correspondent writes: "It is often stated in the Press and by dealers that albumen paper is now off the market and is never likely to appear again. During my visit to the Photographic Fair last week I made several inquiries concerning it. I found that the paper is being made to-day by the Autotype Co., 73, New Oxford Street, London, W.C.1, and this fact may be of interest to many of your readers who have perhaps failed to trace the source of modern supplies. There is, I understand, a steady demand for it, mainly, I suppose, for crystoleum work."

Lancashire Society of Master Photographers.—The fourth annual conference will be held on Wednesday and Thursday next, May 17 and 18, at the Palatine Hotel, Blackpool. Mr. Swan Watson and Mr. Alfred Ellis, president and secretary of the P.P.A., have accepted invitations to be present. Lectures will be delivered by Mr. C. P. Crowther and by Miss Fleming, of Nottingham, the latter on the photography of children. It is hoped that there will be a full attendance of professional photographers in the North of England. All particulars are obtainable from the secretary, Mr. W. H. Hush, 39, Brickfields, Manchester.

Counting Seconds.—Although many dodges for counting seconds accurately have been advocated, photographers know how very easily one may be deceived when working without a watch. Remarking that it was extremely difficult to measure time, the Recorder (Sir Ernest Wild, K.C.) conducted an experiment at the Old Bailey during the hearing of a case last week. A witness had stated that two minutes had elapsed between certain events, but, asked to indicate that time by the words "Go" and "Now" while

counsel checked the seconds with his watch, it was found that forty-five seconds only had passed.

PHOTOGRAPHING MOUNT EVEREST.—The writer of the "Diary of a Man about Town" in the "Evening News" states that Captain J. Noel, F.R.G.S., commanding the photographic section of the Mount Everest Expedition, had a narrow escape while travelling on the Darjeeling-Himalayan Railway. In order to take a quickly-moving picture he had climbed on the roof of the car and was nearly swept off his perch several times while passing under low bridges and overhanging foliage. "He writes home," continues the Diarist, "glowing accounts of what can be done with the Newman-Sinclair cine camera, which appears to be able to do everything but talk the Tibetan language. By using the new motor attachment the camera can be left to take something like 2,000 feet of film all by itself!"

NEWSPAPERS BY PHOTOGRAPHY.—Newspapers by photography are no new thing (writes a correspondent), and many will remember the excellent issues of "The Scientific American" produced entirely by photography a year or so ago, but the photographic edition of the Paris "Daily Mail" may not be so well known. This photographic feat was referred to by Lord Northcliffe in a speech made last Thursday when presenting a gift of £10,000 and £2,500 pension to one of his retiring editors. "The editor of the Continental edition of the 'Daily Mail,'" said Lord Northcliffe, "was, without warning, one night faced with a telephone threat from a number of misguided workers, who at the same time telephoned to the editor of the Paris edition of the 'New York Herald' and combined in a lightning strike. Mr. Goudie (the editor) accepted the challenge, and in a few days produced an almost perfect newspaper by photography. In a fortnight it was difficult to see that it was not a newspaper produced in the usual way from type."

TORONTO CAMERA CLUB.—The thirty-first annual exhibition arranged by the Toronto Camera Club will again form part of the Canadian National Exhibition at Toronto, from August 26 to September 9 next. One of the largest exhibition galleries in the building of applied arts has been placed at the Club's disposal, and will allow of the hanging of upwards of 600 prints. Our Canadian friends hope to receive many exhibits from the mother country. An entry form is obtainable from the Secretary of the Committee, Mr. J. H. Mackay, 2, Gould Street, Toronto, but as little time elapses between now and the final date for the receipt of entries, namely, July 22, no doubt exhibits will be accepted without the accompaniment of the official entry form. The number of works which may be sent by a single exhibitor is limited to eight, an entry fee of 50 cents covering this number. Exhibitors are asked to state the title of each picture, the process used for the print, and also whether the exhibition committee has the exhibitor's permission to allow prints to be reproduced. Exhibits should be sent by post only, and should be declared as for exhibition only and without commercial value. Prints must be mounted, preferably on white or light tone mounts, 16, 20 or 24 inches in height, but not framed.

R.P.S. AFFILIATION OUTING.—The organising societies, for the outing on May 27 are the Hitchin and District Camera Club and the Letchworth and District Camera Club. The route to be traversed is from Hitchin Station, through Charlton, Well-head, Gosmore, and St. Ippollitts back to Hitchin.

Tea will be served at 4.30 p.m. at the Brand Street School Room, after which visitors will have ample time to photograph in the town itself, permission having been obtained to photograph in several interesting buildings.

Arrangements have been made with the G.N. Rly. Co. whereby a party of twelve or more travelling to Hitchin together by any train may do so at a reduced return fare of single fare and a third. For those travelling from King's Cross, special tickets will be issued at 6s. 3d. return, and the party from King's Cross are advised to use the following services :—

King's Cross depart, 1.5 p.m.; Hitchin arrive, 2.16 p.m.

Return :

Hitchin depart, 8.56 p.m.; King's Cross arrive, 10.8 p.m.

Additional trains :

King's Cross depart,	9.20 a.m.	; Hitchin arrive,			10.21 a.m.
,, ,, ,,	11.30 a.m.	,,	,,		12.22 p.m.
,, ,, ,,	12.40 p.m.	,,	,,		1.31 p.m.
,, ,, ,,	1.45 p.m.	,,	,,		2.47 p.m.
,, ,, ,,	2.30 p.m.	,,	,,		3.31 p.m.

Those travelling from King's Cross must apply through their Secretary for tea and railway (special) ticket to Mr. Cannon (address below), while those travelling from other stations, providing the party numbers not less than twelve, should apply to their Station Master beforehand for terms.

Members not using the trains advised should let Mr. Cannon know what train they intend travelling by.

Admittance to the tea will be by ticket (2s. 6d.), and applications for tickets must reach Reg. Cannon, 16, Ickleford Road, Hitchin, with remittance from the Secretary of each Society, *before* May 21, otherwise tea cannot be guaranteed.

Members of the organising societies, wearing black and amber ribbons, will be stationed at points along the route to give any required information or guidance, and will meet parties arriving by train.

Entries for the usual affiliation outing competition will only be accepted from those who sign the attendance book at tea time, and the usual competition rules of the Affiliation Board of Judges will be adhered to. Further particulars may be obtained from Secretaries of affiliated societies, or from the official Red Book of the Affiliation.

INVENTIONS IN COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—In view of the fact that I believe the statements which I made in my previous letters were substantially and in effect quite true, and that only an evasion or perversion of the facts can make them appear otherwise, I am sorry that Mr. Wall, by his communication which appears on page 206, makes it necessary for me to write again.

To begin with, I have tried to make it clear that my object was to produce *extremely tenuous* colourless colloid reliefs, which were subsequently dyed in various colours. I made such relief prints which could be completely dyed up with some of the well-known soluble acid dyes in about 30 seconds, producing colour prints as perfect in every respect as relief prints which would require from 10 minutes to half an hour to dye through evenly with the same dye solutions, and which in a further development and application of the process permitted of making imbibition prints on such hard surfaces as Velox backing paper, with short time contact and entire absence of the dye spreading action which characterised all imbibition prints as previously made, on soft gelatine paper, with the long contact made necessary by the reliefs used by Sanger Shepherd and others. This accomplishment positively had not been anticipated by others.

In the perfecting of this substantially new and really revolutionary procedure I introduced an entirely new and original system of dye bath control, whereby any number of exactly duplicate prints could be made automatically and rapidly, the depth of dyeing depending upon the dye bath composition, and being independent of time of immersion after a certain short period. I well remember how a former pupil of Mr. Wall's, who was employed as my assistant, thought that the way to get a lighter print was to dilute the dye bath with water, and was thunderstruck to find that the composition, and not the strength of the dye bath, was what determined the depth of colour in the print.

Mr. Wall discounts all this by two references to procedures which did not effect these results, and declares in effect that there was no originality in my methods.

Now, as to the facts: Lumière specified the addition of cochineal red to the bichromated colloid coating. Cochineal red is very transparent to the blue and violet light to which bichromated colloids are most sensitive, and while it could conceivably, and probably did, have some restraining effect, it could not serve for the production of "extremely tenuous relief prints." The colour which Lumière

added was not, with respect to bichromated colloid, a true "non-actinic colour," such as specified in my patent, and it is not true that Lumière anticipated that patent.

Mr. Wall now for the first time quotes from a British Sanger-Shepherd Bartlett patent: "It is desirable to add a colouring matter, or preferably bromide of silver, to the gelatine solution." I had never seen this reference, the mention of the colouring matter being omitted in the U.S. patent; but, from my point of view, it is sufficient to know that Sanger Shepherd was not seeking to produce such extremely tennous relief prints as I did, and that he could not have done so if, as stated, he preferred the results obtained with bromide of silver in an uncoloured film. He certainly did not specify the use of a water-soluble yellow dye as used and patented by me. A specific accomplishment which is in effect revolutionary is not anticipated in patent law by steps in the same direction which fall short of the specified accomplishment.

I therefore repeat that Lumière did not anticipate me by ten years, or Shepherd and Bartlett by eight years.

With respect to Mr. Wall's remark that in my patent on Photochromoscope and Photochromoscope camera "there is not the slightest suggestion of a camera" "except" such as appear in title, preamble and claims, and the statement in the body of the specification that "by the use of suitable lenses and colour screens and the substitution of plate holders for the chromogram holders, either form of the instrument may be adapted for making the chromogram negatives," etc., I ask, what more can any reasonable man demand in proof that it was an optical system designed, adapted, and patented for both a viewing instrument and a camera?

Mr. Wall accuses me of trying to be plaintiff, defendant, and judge all at the same time, and says that my statement that the "White" camera infringes my patent carries no weight at all. A statement of fact by an honest man should carry some weight, especially when references are given by which it can be verified. Mr. Wall could have quoted from my U.S. patent claims features which were incorporated in the "White" camera. For instance, claim 9, as follows: "A photochromoscope having a transparent mirror located therein at an angle, so as to reflect and also transmit rays of light, said mirror being so coloured that it will absorb unreflected rays of a character which the mirror is designed to reflect, but transmit rays of the character which the mirror is designed to transmit." Mr. Wall's statement that my attitude in this matter is "curiously unfortunate" is uncalled for. He knows very well that the so-called White camera is merely an insignificant modification of my own, making it no better as a camera, and distinctly less convenient as a viewing instrument.

Mr. Wall's statement that "Mr. Ives was again anticipated by Cros and Du Hauron in this type of instrument" may be taken for what it is worth. The matter has been thoroughly threshed out in the past, and I believe I have always given credit due to others, and claimed only what was my own. The validity of my patents, now expired, was never seriously questioned.—Very truly yours,

F. E. Ives.

1327, Spruce Street, Philadelphia
April 20.

SYSTEM IN HALF TONE OPERATING.

To the Editors.

Gentlemen,—It is interesting to see the above subject crop up for discussion once more, as the general opinion seems to be that the whole business had been thrashed out in the early days and that no more was to be learned in the matter. However, as most of your correspondents seem to agree, the average operator still works by "rule of thumb" method; and if one is to be guided by articles in past numbers of Penrose's Annual, most of them have occasionally obtained perfect negatives, and, while realising that if the exact conditions could be repeated the same result could be gained, have been unable to repeat the performance at will.

In actual practice with both wet and dry plates I have found it necessary to use a much wider screen distance for the 100-line and coarser screen rulings than that given by the mathematical calculations of the Smith-Turner system for when using the latter distances the high-light dots are decidedly round, and will not join at the corners. If we presume that working exactly to the system a perfect negative can be obtained with a 175-line screen, each coarser ruling down to 50-line must be proportionately farther from an ideal dot formation.

In Mr. Bierman's first article he states that:—"There is no theoretical reason why a dry-plate screen negative should not be perfect when it leaves the fixing bath." It would be interesting to know if Mr. Bierman means "capable of giving a perfect print on metal," for in an earlier system of his published in the Imperial Process Plate Handbook, the resulting negatives, from a flat bromide, for instance, with their excessive "penumbra" which partly prints through, would certainly not be judged perfect by a wet-plate operator used to seeing exactly what he has got in the way of actual dot formation.

Mr. L. H. Johnson's advice in your issue of May 5—"to be as exact as possible in applying the working hypothesis . . . that the ratio of screen distance is to screen ruling as the aperture is to camera extension" (which of course is the actual basis of the Smith Turner system), seems to fail for the reasons stated above, i.e., that one cannot be exact to system with the coarser screen rulings and obtain perfect results.—Yours faithfully,

F. B.

Birmingham, May 6.

To the Editors.

Gentlemen,—I am pleased to see Mr. Louis H. Johnson's letter, and to find the subject attracting attention from someone who evidently has some inside knowledge of the process trade.

I agree with most of what he says, but I cannot agree with all his conclusions. The keynote of his letter is, like the scorpion's sting, in the tail, and that is, that the normal distance equation is the last word, and so long as operators will accurately work to it all will be well. But that is exactly what I am attacking. There is a factor missing from the equation, and unless that factor is taken into account equivalent results with different screen rulings are impossible. The effect of blindly following the equation is to shorten the gradation scale with the fine as compared with the coarse rulings, and in the endeavour to overcome this the exposure is divided between several stops of different diameters, which cannot all agree with the equation, and the proportion of the exposure allotted to these stops must vary with different screen rulings. Therefore I contend that if the equation is scientifically correct this should not be necessary, and all screen rulings should render the same gradation with the same stop and exposure.

The effect of diffraction is no pet theory, but is the governing factor that is missing from the equation, and any advantage that can be gained from a study of it is certainly worth while. With regard to speed and quality that naturally follows if the system is right, but, where is the advantage in speed of negative production if the etcher is expected to correct faulty gradation?

If Mr. Johnson had any idea of the criticisms levelled at present-day half tone reproduction, and the efforts that are being made in many quarters to get away from its crudities he would probably think anything worth while that would help to put the process upon a more scientific basis. I agree with him that it does not end with the negative, but the whole process is about as "rule of thumb" as it can well be.—Yours faithfully,

E. A. Bierman, F.R.P.S.

AMERICAN PROFESSIONAL PORTRAITS.

To the Editors.

Gentlemen,—After reading Mr. Mackie's letter in your issue of May 5 I was not prepared for the great pleasure I experienced in seeing the American Portraits at the Photographic Fair.

There was a vitality about them, as a whole, which was quite extraordinary, and the fresh points of view and ease of nearly all the portraits made this part of the Fair an education in itself. Especially charming were the portraits of children, which were, in all cases, delightfully spontaneous. There was about this little exhibition a strong feeling that the authors are keen on their work and love it for itself.

Professional portraiture in England is, on the whole, of a much more conventional type, but then the English public is more conventional than the American, and I do not think that work such as this—much as I admire it—would find a ready sale in England

except among a few advanced members of the community. For most of us who earn our living by photography, I fear, the photograph that is "so clear" still finds the greatest favour among our clientèle.—Yours truly,

(Miss) VIOLET K. BLAIKLOCK.

18, Elsworthy Road, S. Hampstead, N.W.3.
May 6 1922.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

E. W.—Either of the shutters mentioned would give a much greater range of exposure and be more efficient than the roller blind, and are quite worth fitting. We advise you to entrust the work only to the makers of the lens.

J. A.—The copyright is certainly yours, and has been infringed definitely by the newspaper. You should write to the proprietors of the latter pointing out the infringement. They are the people, inasmuch as your customer apparently has not actually copied your photograph, but sent one of your prints to the newspaper.

S. W.—If the pinholes are very small they can be stopped out with a mixture of rubber solution and lamp black, applied as sparingly as possible with a fine camel hair brush. But the remedy is only temporary as a rule, and it is usually best to have a new blind fitted, which can be done by such a firm as Messrs. Peeling and Van Neck, 4-6, Holborn Circus, London, E.C.1.

H. J.—While-you-wait cameras are supplied by Messrs. Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.2, who are agents for all the makes on the market. There is no book on the subject. An ordinary camera is unsuitable because means have to be provided for transferring the exposed metal plate or card in full daylight into a tank where it is simultaneously developed and fixed.

K M.—We do not know of any photographers who make a regular practice of selling negatives for retouching practice, but would advise you to apply to some of the professionals in your own neighbourhood. They might object to parting with them altogether, but might be willing to let you have some rejected poses on loan, to be returned when you have worked upon them.

C. G.—We are sorry that we cannot give formulæ for waterproof inks, as the makers keep these to themselves. Ordinary Indian ink becomes waterproof if mixed with a little bichromate of potash solution when mixing. We believe that some makers use a small quantity of a solution of shellac and borax in making their inks. The solution is made by mixing 1 oz. borax, 5 ozs. shellac in 20 ozs. hot water. Keep hot till dissolved, allow to cool and settle, and decant clear liquid.

U. F.—(1) Owing to the very high printing costs many photographic text books are out of print at present, but you can almost certainly get "Practical Lantern-Slide Making," by G. T. Harris, second-hand from Messrs. Foyle, 121-123, Charing Cross Road, W.C.2, for a shilling or two. (2) Demonstrations of lantern-slide making are frequent fixtures at photographic societies; probably there is one in the fixture list of the Wimbledon and District Camera Club, the secretary of which is Mr. F. J. Gittins, 39, Ashcombe Road, Wimbledon.

H. B.—The only two suggestions we can make for the improvement of the apparatus (which has little in common with that described by Mr. Lockett) are (1) to line the box containing the burners with a matt white coating, such as a matt enamel paint or white asbestos boards, and (2) to use one thickness of matt opal instead of ground glass. The former of these suggestions will give you a good deal more diffused light, and the opal will diffuse the light still more, though we are afraid it will lengthen exposures unduly. If these means are not satisfactory we are afraid that the only thing you can do is to fit a condenser.

J. D. T.—Yes, for distant scenery, particularly in regard to pictorial effect, there would be an advantage in fitting an adjustment so as to lengthen the focal length of your lens to, say, 16 ins. The extension of your half-plate camera would probably allow for the use of this focal length, perhaps a little more, say up to 18 ins. It is almost inevitable that the fitting of an attachment impairs slightly the definition of an anastigmat lens, but considering the relatively narrow angle over which the latter will be used we do not think that is very much to trouble about. Of course the F.No. (marked) will be increased in proportion to the new focal length.

M. E.—The photograph which you have taken, provided it was not taken to the order of the girl, is your copyright, and you can do what you like with it. We do not think that the fact that it bears a certain resemblance to the poster would be ground for action on the part of the company. Certainly there would be no case whatever as regards copyright for the suggestion that you were infringing their poster. On the other hand, if your enlargement is strikingly similar to the poster, there might very likely be strong objection on the part of the company on the ground that the use of the enlargement was leading the public to believe that the goods you are offering for sale are theirs.

E. M.—(1) Your present lens is a very old one, but the makers had a good reputation in their time, which was between 50 and 60 years ago. A modern lens of the same type by a good maker would most probably be superior, but would not compare with a good anastigmat. (2) As a rule it must be assumed that lenses by good makers are worth the price charged for them or the demand would not continue. It is impossible to establish a ratio between price and quality as the quality of the lens is not a measurable quantity. A lens that is only a little better than another may well be considered worth twice as much or even more. (3) The Aldis lenses offered by the Disposals Syndicate are certainly cheap, even after paying for an iris to be fitted, but it must not be forgotten that they were made to cover 5 x 4 plates. They may cover larger plates satisfactorily, but you must take the risk. You do not mention the size of plate you wish to cover nor the length of your studio. For general work, mainly cabinets, a 16-in. lens is a favourite for large studios, and a 10 to 12-in. for shorter rooms. A second-hand lens by a good maker is always worth nearly its cost for re-sale if you have not paid too much for it.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3237. Vol. LXIX. FRIDAY, MAY 19, 1922. Price Fourpence.

Contents.

SUMMARY.

In the King's Bench Division of the High Court, on May 9 and 10 last, before Mr. Justice Swift, the question of the rates chargeable by electric supply companies for current supplied to studios for purposes other than ordinary lighting was the subject of legal argument by counsel respectively representing the Westminster Electric Supply Corporation, Ltd., and Wykeham Studios, Ltd. Remarking that the case might raise important points in the supply of electricity, Mr. Justice Swift reserved his judgment. (P. 297.)

In the present chapter of the series of articles on the business side of professional photography, "Pelham Swinton" describes the organisation and use of a card index system for dealing with the execution and booking of orders in a portrait business. (P. 291.)

The first meeting of the committee appointed by the Board of Trade under the Safeguarding of Industries Act respecting the sale of German scientific goods in this country was held on Monday and Tuesday last. Evidence was given by Mr. Conrad Beck and by Mr. A. Dennis, of the Houghton-Butcher Manufacturing Co., among others. (P. 298.)

In a contributed article, Mr. B. R. Rawkins recommends a formula for the acid amidol developer suitable for bromide and gaslight papers, and gives directions for making it up in bulk. (P. 293.)

In a leading article we refer to a few of the practical points connected with the making of a stock of cloud negatives, particularly for use in printing-in on development papers. (P. 290.)

In his Paris Notes, M. L. P. Clerc discloses the method for the extra-sensitising of Autochrome plates worked out some few years ago by M. F. Monpillard. (P. 294.)

Experiments in the use of spent developers as desensitisers are described by Mr. J. G. F. Druce, M.Sc. (P. 296.)

Further particulars have been published of the Steigmann process for the simultaneous extraction of silver from used fixing baths and the regeneration of the hypo. (P. 289.)

A process for making reproductions of pictures on curved surfaces, such as vases, is the subject of a recent patent specification. (P. 299.)

Hungary and Brazil, having subscribed to the International Copyright Convention, the 1911 Copyright Act has been extended to Brazilian and Hungarian authors and works. (P. 300.)

In interior architectural photography advantage can very often be taken of the high view point obtainable by use of the lofty pair of steps available in many churches and cathedrals. (P. 290.)

In the use of a small hand camera on a tripod the wire-frame direct-vision finder is of great advantage in arranging the subject. (P. 290.)

EX CATHEDRA.

Charges for Electric Current.

The action brought by the Westminster Electric Supply Corporation, Ltd., against the Wykeham Studios, Ltd., in reference to the charge for electric current used in the latter's establishment for purposes other than ordinary lighting was heard in the King's Bench Division of the High Court on Tuesday and Wednesday in last week, May 9 and 10, before Mr. Justice Swift. As shown by the report of the hearing which appears upon another page, counsel for the plaintiffs and defendants agreed upon such matters particular to the case as the quantity of current consumed, thus making the action a clear test case respecting the right of an electric lighting company to determine the rates at which it should supply current for purposes other than ordinary lighting. After hearing the legal arguments advanced on both sides in interpretation of the Acts empowering electric light supply companies, Mr. Justice Swift reserved his judgment, and thus the issue of the dispute may not be available for some little time. As was represented by the plaintiffs' counsel, the judgment is likely to have far-reaching effects as regards the supply of current at "power rate" not only to photographic studios but to many other classes of consumers.

* * *

Hypo Recovery.

In the current issue of "Photographische Industrie," Herr A. Steigmann has an article which gives some further particulars of the process patented by him for the regeneration of fixing baths with simultaneous precipitation of the silver contained in them. As already pointed out in our issue of January 6 last, the substance which serves this double purpose is sodium hydrosulphite, which, according to Herr Steigmann, reacts with the double hyposulphite of silver and sodium in the fixing bath, throwing down the silver in the metallic state and producing a quantity of hypo equivalent to that previously combined with the silver, together with sulphur dioxide. It is now stated that the process takes place satisfactorily at the ordinary temperature, provided that a sufficient time is allowed. On the other hand, the hydrosulphite should be added as soon as the fixing bath has reached a state of exhaustion. If baths are allowed to accumulate for treatment together, other decompositions take place, resulting in the formation of silver sulphide, and thus interfering with the production of the silver in the metallic state and also with the re-use of the solution. Herr Steigmann estimates that the silver in ordinarily used fixing baths ranges from 3 to 4 gms. per litre, requiring about 6 gms. of hydrosulphite, or better 8 gms., and from 1 to 5 gms. of caustic soda. It is claimed that the solutions remain practically odourless during treatment, but it is not clear whether this is the case with fixing baths of the acid type, or whether the process is applicable to them without modi-

fication as regards the quantity of added alkali.. We cannot help thinking that while the method may be an excellent one for throwing down the silver, its value from the point of view of regenerating the hypo for use is rather doubtful, at any rate in the case of the acid or hardening fixing baths now so much in use.

* * *

View Point in Interior Work. A good many photographers, while fully alive to the importance of a view point in many branches of work, do not appreciate this fully in architectural interiors. Some time ago we were shown a fine photograph of the interior of a famous abbey, showing details from a point of view not generally attempted, the whole particularly well rendered from the point of view of perspective. Subsequent conversation elicited the fact that the photographer had fixed his camera to the top of an exceedingly high step ladder, such as is generally to be brought to light in these buildings by judicious treatment of the sacristan. Another advantage in this class of work, following from the higher point of view, is that objects not contributing to the beauty of the picture may thus be very conveniently dodged or subdued. We refer to stoves, chairs, and the hundred and one things that render difficult the making of a pictorial representation of interiors. The best way to fix the camera to the steps is to insert four sharp shoemaker's " awls " into the steps at the corners of the camera base. The exposures may be made from the ground, using an extra long release, or, if the shutter has a trigger release, a piece of thin string may be made to serve.

* * *

Photographing Altars. The photographer who attempts church interiors is often working under a difficulty when he has to photograph altars, the candles upon which are to be rendered burning. Even if the best of backed plates or the most non-halative film is employed in such circumstances the flames of the candles are represented as large circular blobs of whiteness, due to the irradiation of the emulsion. There is one way in which candle flames may be rendered realistically, and that is by giving a full exposure to the subject without the candles being lighted. At the end of this exposure the lens is capped and the sacristan asked to light all the candles. This done, a further exposure of twelve or fifteen seconds is given, which will result in the images of the candle flames being rendered as they appear. Even under these conditions a well-backed plate or a film should be employed. Another point in work of this kind is that a panchromatic emulsion should be employed, since much of the composition consists of rich colouring, which, if improperly rendered, causes the picture to be disappointing.

* * *

The Small Camera on a Tripod. The small camera fitted with a large-aperture lens is so efficient as a hand camera that many workers do not seem to realise that there are times when short exposures upon a tripod may be given, effecting a very great saving in time in comparison with that needed for larger apparatus. When using the watch pocket instrument as a stand camera, there are one or two points that are often overlooked. As regards attaching the camera to a tripod (which may be of the telescopic variety) it is better to use a tripod board or adapter rather than screw the camera to the tripod, even if a bush is fitted, which is not always the case. For arranging the subject a wire-frame direct vision view-finder is of immense advantage, and should always be used in preference to attempting to compose the image upon a minute focussing screen. No worker who has tried both methods would willingly return to the latter, and it is a great pity that small cameras are not more frequently fitted with this most valuable accessory. Lastly, the exposures should be made with a flexible release, since as a rule it is not easy to expose for short periods without risk of shaking the camera, if the trigger release is used. In this case, an attempt should be made to steady the camera with the hand.

CLOUD NEGATIVES.

Formerly, it was easy to purchase cloud negatives in any size on either glass or film, the carbon film clouds of Mr. Green, of Berwick-on-Tweed, being very fine. These are no longer listed by the dealers, and it is to be presumed that, as articles of commerce, they have ceased to exist. This is, perhaps, not altogether to be regretted, as it was sometimes rather embarrassing for an exhibitor to find his cloud effect duplicated in one or more other pictures in the same show.

A considerable amount of judgment has to be exercised in the making of cloud negatives for printing-in, as distinguished from those in which the cloud effect is in itself the point of interest, as the latter class includes bold, stormy skies, sunsets and sunrises, while for the former the more common-place, but still beautiful, cumulus or cirrus forms are more generally suitable.

As the forms of these clouds vary during the course of the day it is desirable to mark upon each negative the hour at which it was taken. Although it does not matter in ordinary commercial work whether a mid-day sky is printed into an evening negative, so long as the general effect is good, critics may not be so merciful if the same thing is done in an avowedly pictorial composition. For important work it is even desirable to take the cloud and landscape from the same spot at the same time of day, but, of course, not necessarily on the same day, as the conditions are often not favourable for so doing.

Although clouds may sometimes be secured upon the same negative as the landscape subject, it is not well to rely on doing so very often, as it is next to impossible to obtain the necessary contrast in the sky if there is strong contrast in the foreground. Graduated colour screens have been tried to compensate for this disparity, but they are obviously of limited application, as the gradation must extend across the entire subject, irrespective of buildings or clumps of trees.

Fairly good cloud negatives may be obtained upon slow ordinary plates without a filter, but the occasions upon which this is possible are so few that it is well always to use colour-sensitive plates with a suitable filter. A deep yellow filter is usually not the most suitable. Even a deep blue sky does not give the impression of black to the eye, which is the result of the total elimination of blue resulting from too deep a filter. Exposure may present some difficulties at first, but a modification of the strip test, as used in bromide printing, will greatly help in this direction. As clouds are constantly moving, it is impossible to employ the ordinary method of drawing the shutter out in sections, but it is possible to arrange strips of card to partially mask the plate so that, say, three quite independent exposures can be made upon the same plate, giving double the time at each change. This test may be made at home, and, if possible, the time taken to secure a full tint upon a Watkins or Wynne meter should be noted, the meter being pointed to the

sky. Subsequently, the exposure may be increased or diminished in proportion to the meter time, stop, plate and filter being unaltered.

It might not be suspected that halation would cause trouble in this class of work, but it will be found that much better tone values will be obtained upon a backed plate or a film than upon an unbacked one. Films are particularly suitable for cloud work, as they can be printed from either side, so that the clouds may be lighted from the same direction as the landscape.

The camera should not be pointed up to the sky, but should be kept level and the front raised, so that the clouds appear as they would if taken with the landscape. Any keen observer of nature would detect the error of printing clouds situated near the zenith into a position near the horizon. In order to see readily which is the top of the negative a small portion of the view should be included upon the plate. Assistants have been known to print-in clouds standing upon their ends, though this is less likely to occur than printing them upside-down.

It has always been customary to make cloud negatives very thin, and there is no disadvantage in doing so for printing-out processes. With bromide printing and enlarging on the other hand it is better to aim at greater density, so that there is not such a great difference between the two exposures. If the view negative requires twenty seconds in the enlarger, and the cloud only two or three, a very slight error in exposure of the latter will spoil the print, while, if the sky required approximately the same exposure, the percentage of error would be much less.

As a general rule, it will be found easier and more expeditious to put in skies upon bromide prints by means of the enlarger, even if the prints are the same size as the negative. This course allows of the cloud being enlarged or reduced to any degree, or of being used on either side. Many failures result from excess of carefulness, that is to say, a mask which exactly follows the outline of the view is cut and held fairly close to the paper. This almost always results in a very perceptible band (either lighter or darker than the sky) showing at the junction, while trees often show white paper between the boughs. A roughly-cut mask kept well in motion, and allowing a slight overlap, will, as a rule, be found quite satisfactory.

THE BUSINESS SIDE OF PROFESSIONAL PHOTOGRAPHY.

(In the present chapter of the series by the professional photographer contributor who is using the pseudonym "Pelham Swinton," the writer describes a card index system for keeping under view the orders received from customers and their execution in the workshops and for providing the necessary records and reminders for collection of payments. The previous chapters have dealt with the general economic position of the photographer and the relation of a studio to its customers from several points of view. In the chapters still to appear "Pelham Swinton" will describe a system of ascertaining the cost of the goods supplied in a portraiture business and with the procedure of collecting accounts appropriate to a business such as that of a portrait photographer.)

III. THE PHOTOGRAPHER'S CLERICAL SYSTEM.

Of all the desirable factors in the composition of a "compleat" photographic business, the clerical department is the one most frequently neglected. The photographer who is occupied in operating, in the selection and display of specimens, and in the superintendence of his workrooms has little inclination to give attention to book-keeping. Besides this, it is an unsavoury subject. System of any kind is unpalatable to the artist; but a *clerical* system is nothing short of an abomination—an incubus—an iron shackle invented by accountants and fussy materialists wherewith to fetter æsthetic souls to the earth. In these unromantic days, however, it is perhaps wiser, however unpleasant it may be, to tolerate some species of a clerical system—even if it be merely to satisfy the impertinent questions of the income-tax inspector; and I propose to describe here a simple but very reliable system, sufficiently elastic to suit any size of photographic business, and one which, being self-checking, almost entirely eliminates the possibility of error, and reduces to the minimum the time spent in supervision.

At present the photographer is usually content to leave such things in the hands of his receptionist. If the receptionist happen to be a woman of business instincts then he is fortunate; but if she be merely a young lady whose gaze is entirely transfixed by the glitter of possible matrimony, and to whom book-keeping and correspondence seem even more unnecessary than to the photographer himself, then trouble may safely be predicted for that photographer. It were far better that a portrait lens were hanged about his neck, and that he were drowned in the depths of his developer, than that the inevitable wrath of his customers should descend upon him. Let it be clearly understood that I have no wish to discredit matrimony. I am told that it is a beautiful state, and I see no reason why receptionists, any more than photographers, should be debarred from entering therein. But when young persons of either sex accept responsible commercial posts, they should see that matrimony, like golf, is relegated to half holidays and spare moments.

The photographer's clerical system may be divided into three functions: (1) The recording of the sitting and the dispatch of the proofs; (2) the entry of the order, and the dispatch thereof; (3) the entry of the sum due, and the collection of the amount from the customer. In the case of a purely cash business this last function, of course, does not exist; but we shall presume that the business in question is a credit one.

Charge to ROBT. D. BROWN, Esq., 596, Tuppeny Road, London, S.E.69.

Fig. 1

First of all, a card such as that illustrated in Fig. 1 is printed. It is advisable that this be of thin card or thick paper, measuring 8 in. by 5 in., and it is not necessary that

it be actually printed. A thousand or two can be run off very cheaply by any firm which undertakes the printing of letters, etc., by means of duplicating machines. Besides these cards, four standard 8 by 5 card index drawers are required.

When the customer has been photographed, her name, address, the date of the sitting, and the negative number are entered at the top of the card. At the same time, by means of a piece of carbon duplicating paper, a duplicate is made. These two cards are then clipped together with an ordinary wire fastener, and placed in drawer-file No. 1. At the front of this drawer are index cards labelled "C. de V.," "Cabinet," "8 in. by 6 in.," or any other shape or size of negative in common use by the firm. Behind one of these the two cards are placed, according to the size of portrait selected by the sitter. In due course the negatives are given to the receptionist to be named and numbered, and this information she obtains from the cards, which she replaces as before.

If the proofs have been promised by a certain date this fact will have been noted at the left-hand bottom corner of the cards, and the receptionist, now reminded of the fact, will send a note to the printer accordingly. The printer writes the number of the negative on the back of each proof, and when these come down to the reception room the cards are again referred to for the name and address, and the date of the dispatch of the proofs is entered below the "date promised." The cards are now replaced in the drawer, but behind their original position, where there is a double set of alphabet index cards. The cards are placed in the first alphabet, behind the initial letter proper to them, and here they lie until the customer gives her order.

On receipt of the order the details thereof are added to both cards—the size and style, instructions, etc., being entered each under its proper heading, and the number of prints, coloured prints, or frames, written in their respective columns—thus enabling one to see at a glance the kind of items composing the order, and to prevent an order for two frames being mistaken for an order for two prints, or a coloured print for a frame. Besides this, the date on which the order is received is entered at the left bottom corner, and also the date for which it is promised; while the name and address of the person to whom the whole is chargeable is written in the space provided—if the person to be charged is not the person photographed. Otherwise, this space is left blank.

The two cards are now separated, the rough proofs being clipped to the duplicate card and sent to the printer, and the other being replaced in the drawer, but still farther back, in a second alphabet, of which there is a double set also.

Thus we have in this first drawer: (1) A set of three or four index cards representing the different sizes of portraits. Here the cards lie until the dispatch of the proofs, the completion of the first clerical function. (2) Two double sets of alphabet index cards. Here the cards lie, in the first set, until the arrival of the order, and in the second set until the order is dispatched. This completes the second clerical function.

The reason for the use of a *double* set of alphabet index cards, in each of these two cases is as follows:—During the month, say, of January, all cards are placed in the *first* alphabet of each set. On February 1 the second alphabet in each set is placed in front of the first, and all cards during February are placed in this. On March 1 the first alphabets fall to be used once again, but it will be found that a few cards placed in these during January still linger behind. These cards represent, in the one case, sittings for which no order has been given, and, in the other case, orders on hand which have been unduly delayed. These cards must now be extracted, and, in the case of unordered proofs, a carefully-worded letter is sent to the customer asking if the proofs submitted on such-and-such a date have met with approval, and how many finished copies will be required. She will then either give an order or arrange a second sitting. In the case of orders on hand which have been delayed, it is necessary merely for the photographer to pay a visit to his workrooms, the cards in his hand, and discover the cause of the delay. All such overdue cards should be kept either by the receptionist or by the photographer in a prominent place where he or she will see them every morning, and where they will lie until the matter is rectified.

Thus it will be seen that, provided the alphabets are changed over regularly on the first day of each month, or at any other convenient period, it is impossible that any proofs can remain unordered or that any order be overlooked or forgotten.

Now let us follow the course of the duplicate card to which the rough proofs have been clipped. This goes to the printer—if the negatives have been retouched before proofing—and the printer gleans from the card all the instructions which are applicable to him. When he has completed the order the card is passed on, along with the prints, to the mounter, and thence to the finishers. It is thus unnecessary for the photographer or the receptionist to waste time trotting from room to room giving verbal instructions. Everything is here in writing for each department to see. Meanwhile, in the reception room, the other card remains in the file; and, should the customer call while the order is in progress to ask some question, or to make some alteration, it is necessary only for the receptionist to refer to the card, and in a moment she is conversant with all the details of the order and is able to talk intelligently regarding it. This is an obvious advantage. Were the details of the order buried in a book several minutes might be spent before they could be traced, and customers are apt to forget that one has other customers and that the human memory is imperfect.

When the order is completed the duplicate card accompanies it down to the reception room. The receptionist extracts the corresponding card from the file, checks and dispatches the order, and enters the date in the column headed "Dispd." The duplicate card is now destroyed. Now the back of the original card is printed with the usual ledger ruling, as in fig. 2. Here the name and address of

Name: BROWN, ROBT. D. *Address:* 596, Tuppeny Road, London, S.E.69.

Fig. 2.

the person chargeable are written, and the items and amounts entered below. At the same time these details are entered in the firm's day book, which must contain a continuous record of the daily turnover. This simple operation over, the card is dropped into drawer-file No. 2. This is the ledger file, and contains all the outstanding accounts. It is of unusual composition, and may at first seem somewhat elaborate. It is composed of no less than twelve sets of alphabets, one for each month of the year, and with the name of the month on a card in front of each set. The current month is kept always at the front of the drawer, and the remainder in their sequence behind it. If the current month be March, then the remaining eleven months will stand behind in order—February, January, December, November, etc., with April the farthest back. All cards during March are dropped into the March alphabet; then on the first day of April the April alphabet is brought from its place at the

back and placed in front of March. At the same time, as in the case of the other file, any cards which still remain from the previous April are extracted. Such accounts are now a year old; and if they have not already received very special attention it is time that they did.

Thus we see once more that no card can be overlooked, and all accounts belonging to each particular stage are automatically grouped together. The alphabets toward the front of the drawer will always be fairly full, and a gradual thinning will be noticeable in those receding toward the back. By a monthly supervision of these alphabets it is possible practically to eliminate the risk of bad debts.

In the case of re-orders the same system is employed, with the exception that the card goes directly into the "order-on-hand" alphabet in file No. 1 and the duplicate card goes straight to the printer. Also, of course, the spaces for entering details of the sitting and proofs are unused.

Sometimes it happens that the entire order is not sent down from the workrooms at once, and that, say, twelve ordinary prints are finished before a coloured print or an enlargement. In this case the duplicate card is sent down along with the first portion of the order, so that the receptionist may know whose order it is, and be able to dispatch that portion, if desired. In such a case the items dispatched, as well as the date, are entered in the "dispatched" column; and the account is not charged up until the whole order has been dispatched.

When the account for the order has been paid the card is placed in one or other of the two remaining files. No "paid" card must be left to clog the ledger file. These two files contain one alphabet each, but more subdivided than the simple A-B-C type. Alphabets can be obtained with various subdivisions, such as Ab-Ac-Ad-Ae-, Ba-Be, etc., which render a card much more readily found. An alphabet with forty divisions is most suitable in this case. If the "paid" card represents a re-order it is placed in No. 3 file, where it lies for reference purposes; but if it is a card of a sitting and first order, it is placed in No. 4, and thus we have a negative register without further trouble. And not only does this constitute a negative register, but each card contains every detail of the customer's first order, all instructions applicable to future prints from her negatives, how much she paid, and how long she took to pay for it.

At the end of each year the contents of these two files are transferred, *en bloc*, to cheap cardboard receptacles of similar dimensions, and having the year written on each. Of course, many accounts belonging to the old year will remain unpaid during the first few months of the new year; and such cards, when paid, must be placed in the file proper to their year, and not in the current file.

With the above system it is possible to run any photographic business smoothly and satisfactorily. And the elasticity of the system is unlimited. In the day of success all that the photographer need do is to increase the number of his files. And, when tempted to cavil at the daily discipline demanded by clerical work, he should remember with meekness and gratitude that, compared with systems required in other kinds of business, it is mercifully simple.

PELHAM SWINTON.

ACID AMIDOL FOR THE BUSY PRINTER.

THE respective merits of amidol and M.Q. have often been discussed in these columns, but there is no getting away from the fact that amidol is extremely popular with the trade printer. The fact of it being a neutral solution (or practically so) makes it suitable for the water of some districts in preventing the formation of insoluble compounds, which give the prints a gritty surface. It is very simple to make up, and has considerable covering power.

The chief disadvantage of amidol is that it does not keep in solution. Three days is considered to be its effective life, but I have found that with both neutral and acid amidol the covering power is very feeble after two days. However, this is not such a formidable disadvantage when one can keep a stock solution of sodium sulphite and add dry amidol as required just before using. After the continuous use for some months of an acid amidol developer for many thousands of prints and enlargements on bromide and contact prints on gaslight papers, I find it excellent, clean-working, constant, and what might be called a "business proposition." I do not notice any improvement in the keeping properties of acid amidol, but it is quite regular in use, due, I think, to the acid sulphite solution being constant and not so liable to deteriorate as a plain solution. The image builds up in the usual way, and development of bromides is complete in two minutes with ½ grain of potass bromide to the ounce of developer. Some makes reach finality in 1½ minutes. Gaslight prints develop in one minute, or sometimes less with the vigorous papers. Well diluted, it gives excellent colours on the slow development papers.

The formula given below is suitable for practically all the development papers. The acid sulphite solution is made up in a four-gallon jar with a wooden tap fitted for drawing off the required amount. This jar is placed on a strong shelf at a convenient height and a small hanging jar is kept under the tap in case of slight leakage.

Stock Acid Sulphite Solution.

A	Sodium sulphite (cryst.)...	8 lbs.
	Water (hot) about ...	3 gallons (480 ozs.)
B	Potass metabisulphite ...	2½ ozs.
	Hot water	½ gallon (80 ozs.)

When cool mix by slowly adding the metabisulphite (A) solution to the sulphite (B) solution, and make up to 4 gallons with water. To make a working bath, use the following proportions.

Working Bath.

Acid sulphite solution	40 ozs.
Water	40 ozs.
Amidol (dry)	200 grs.
Potass bromide	(See below)

The potass bromide plays such an important part in affecting the colour of the image, time of development, and prevention of fog that special care must be taken to ensure accuracy. This salt should be made up in a 10 per cent. solution, and always accurately measured out, bearing in mind that the average amount required for bromides is ½ to ¾ grain to the ounce of developer. In a 10 per cent. solution every dram contains six grains, every 10 minims contains one grain, and every min m (or drop) contains 1/10 grain.

Bromides and gaslights develop to a nice black colour with ½ grain of potass bromide to the ounce of developer, and to obtain a warm or olive black on gaslight, chloro-bromide, or studio development papers, it is necessary to add more (up to 6 grains to the oz.) And also to dilute the developer. It is interesting to note that in diluting the developer for gaslight papers the contrast with the vigorous grade is increased, but

quite the reverse happens when using a diluted developer for bromides. Potass. bromide has little or no influence upon the contrast given by any particular paper, but it is in practice absolutely necessary to prevent fog and to control the colour of the image. Absence of bromide will give quite a blue colour on gaslight, but the whites will often be degraded.

The following table may be useful for reference when a particular colour is desired:—

Process.	*Grade.*	*Exposure.*	*Potass. Brom., grains per oz.*	*Colour.*
Gaslight.	Vigorous, normal.	Correct.	¼ gr.	Pure black.
,,	Soft.	Double normal.	1 ,,	Olive black.
,,	...	4 times normal.	4 ,,	Brown black.
Bromide.	All.	Correct.	¼ ,,	Pure black.
,,	,,	Normal. plus ⅓	1 ,,	Greenish black.

The latter colour is produced on bromides that are to be toned in the hypo-alum bath. The development is stopped short of finality, so as to ensure a warm sepia tone in this toning bath. Bromides developed to finality give a rather cold tone in hypo-alum.

Fixing Bath.

Hypo	18 lbs.
Hot water	34 quarts.

When cool add the following solution:—

Potass metabisulphite	5 ozs.
Hot water...	2 quarts.

It is convenient to make up a large fixing-bath for a busy man. The formula is as given above. I am lucky enough to have a large white earthenware sink holding 40 quarts easily, and this is fitted with a pull-out plug. There is also a steam pipe fitted under the sink for use in winter or on cold days.

B. R. Rawkins.

PARIS NOTES.

An Unpublished Niépce Letter.

We owe to M. G. Cromer, well known for his writings on photography and an enthusiastic collector of documents relating to the history of photography, the rediscovery of an unpublished letter of J. Nicéphore Niépce. This letter, bearing the date of May 26, 1826, and addressed to Niépce's son Isidore, has hitherto been known only by a few lines quoted in Fouque's work of 1867, "La Verité sur l'Invention de la Photographie." It alludes to the images which for some time prior to the writing of the letter had been obtained by Niépce in the camera on pewter plates sensitised with Syrian asphalt. It was these results to which Niépce applied the description "points de vue d'après nature." A collotype facsimile of the letter has been published in the March issue of the Bulletin of the French Photographic Society.

A new example of the Russell Effect.

The late Professor W. J. Russell, as is well known, made numerous observations some years ago on the effect of exposing a photographic plate in the dark in contact with pieces of wood, etc. By allowing, for example, a piece of wood to remain for a sufficient time in contact with the emulsion, an image was produced on the plate showing by the different densities the fibres of the material characteristic of spring and autumn growth. A Parisian engineer, M. Bardier, has obtained the same results with a sample of lignite which had become almost converted into jet, and thus was many thousands of years old. The specimen was obtained in the course of a visit to Madagascar. Two faces of the specimen were polished in a dark-room, one parallel to the fibres of the fossilised wood, the other perpendicularly to these fibres. Both surfaces, after contact "exposure" for several hours, showed a quiet sharp image (more pronounced than in the sample itself) of the yearly rings in the wood and of the fibrous structure. The image was slightly more intense in the case of a second series of exposures made after exposure of the lignite to light.

M. G. Reboul, Professor of Physics in the University of Poitiers, has recently found that by wrapping a photographic plate in black paper and by bringing two spring electric contacts on to the paper in such a manner as to produce a difference of potential of about 1,000 volts (the effect begins at about 200 volts) there is obtained after development an intense image showing the structure of the paper with considerable fidelity. The action is more pronounced towards the positive pole. Check experiments were made, so as to eliminate pressure of the terminals as a possible cause of the phenomenon, and it would seem that successive falls in potential to points where there is discontinuity of resistance produce minute discharges, accompanied by radiation which is invisible yet exerts an action on the photographic emulsion.

Orthochromatic Sensitizing.

About the year 1912 a French expert in orthochromatism, M. F. Monpillard, succeeded in increasing the sensitiveness of Autochrome plates to a considerable degree, about 30 times. In collaboration with M. L. Gimpel, a worker of great experience in the use of the Autochrome plate in Press photography, he obtained in good light exposures of the order of 1-100th of a second, and even was able to make slow shutter exposures of scenes on the stage under the ordinary theatre lighting. A number of these results were shown at the time at a meeting of the French Photographic Society, and were greatly admired. The process was also applicable to ordinary plates, conferring upon them both a greater degree of colour sensitiveness in addition to general speed, and rendering them exceedingly effective for photography by artificial light. The extra-sensitised plates had, however, one great defect; they would keep for only a few hours, for not more than a day at the longest. M. Monpillard, however, hoped to overcome this difficulty. The method used for the extra-sensitising was not published at the time, but a sealed packet descriptive of the principle was deposited with the French Photographic Society. Recent circumstances having prevented M. Monpillard from continuing his work, the contents of the packet have been published at his request, and it has been disclosed that the secret of this extra-sensitising consists in the addition to the mixture of the usual isocyanine and carbocyanine dyes (pinaverdol, pinacyanol, etc.) of a small quantity of silver chloride previously dissolved in dilute ammonia. It is essential that as soon as the sensitising bath has been used any adhering liquid shall be rapidly removed with a whirler and the plates dried by a rapid current of air.

Process Emulsions.

The manufacture of emulsions of fine grain and great contrast, as required in photo-mechanical work, has long been neglected in France, but two emulsions for this purpose have recently been introduced. One of these is the "Collodium" of Guilleminot, Boespflug et Cie., its name being chosen as an indication that the plate serves as a substitute of wet collodion. The other is a slow stripping paper, issued as "Rex," by MM. Michel, Paillot et Cie.

X-Ray Work.

A Parisian medical practitioner of radiography, Dr. A. Zimmern, has recently observed that, without the aid of an intensifying screen, exposures may be made on X-ray plates with a reduction of about 35 per cent. in the time by previously heating the plate to 110 deg. F. Other conditions remaining the same, the same density is obtained on the warmed plate in this lesser time as that produced when working at 60 deg. F. Unfortunately, the installations commonly used for X-ray exposures are not well adapted for making use of this observation.

Apropos of X-rays, it may be mentioned that a recent paper by M. F. Holweck, a student and collaborator of Madame Curie, has gone a long way to step the gap which hitherto has existed between ultra-violet and X-rays in the great series of waves propagated with the same speed as light. This experimenter has been able to produce X-rays of relatively enormous wave length (extra soft rays), forming a continuous series with the ultra-violet rays of very short wave length obtained in the United States by Millikan.

Stereo-photo-topography.

An interesting demonstration has been arranged for the scientific section of the French Photographic Society by M. J. Prédhumeau of his stereo-topometer, the construction of which I mentioned a few months ago ("B.J.," January 13, 1922, p. 15). The two negatives are taken from two stations, the separation of which is preferably 500 times the average separation of the eyes. The exposures are made on the two halves of a slow fine grain plate in a stereoscopic camera provided with two lenses, which are alternately uncapped. The centre line at each exposure is parallel to the straight line joining the two stations, and the optical axes are horizontal and perpendicular to the line of the stations, the various adjustments being made by means of a theodolite serving as a support for the camera and by aid of a sight which for each exposure is placed at the station not occupied by the camera, that is to say the theodolite and sight, each on a tripod, exchange places between the two stations.

In using the negative thus obtained it is replaced in the same camera as that in which it was exposed so as to take up precisely the same position as that when the exposures were made. The camera is then placed in the stereo-topometer with the same inclination of the centre line as that which was given to it when making the exposures, this line being thus obtained parallel with the base. To each objective is attached a converging lens of 32 in. focal length, and the negative is observed from behind by means of a stereoscope having a magnification of about ten times, and fitted with prisms for reversal of the images. As a means of receiving in the stereoscope the light which comes from the objective, there is placed behind each of the elements of the stereogram a lens of plano-convex field having its focus at the exit node of the corresponding objective. The combining apparatus includes, in front of the photographic camera, a large frame turning on a vertical axis. A movable carriage on this frame carries with it a vertical rod, along which can be raised or lowered a "voyant" (a positive transparency of a flag or other design), lighted from behind. The various movements of the "voyant" are controlled partly with the hands and partly with the feet of the observer using the stereoscope. At the instant when the flag (an image of which is projected on to the negative by each objective) is seen to come, in the stereoscope, exactly on a point of the subject, the "voyant" then occupies in space the position where the subject appears to be reconstituted stereoscopically. Then by means of a pantograph connected to the "voyant" the lines of the subject or the horizontal sections of the ground showing the configuration of the latter can be traced on the plate. The great advantage of this apparatus is that all the registrations are done in the photographic camera used for taking the negative and not in the stereoscope, as is the case with the von Orel stereo-autograph. The whole construction calls for few exact adjustments; only the pantograph and its connection to the "voyant" require to be made with great accuracy.

Cinematography.

A very ingenious system in cinematograph projection has just been worked out by M. Lenouvel, Professor of Physics in the Rouen High School. In seeking to simplify, for the purposes of his class instruction, the alternating projection of animated photographs and ordinary lantern slides, M. Lenouvel has at the same time obtained an improvement of more than 300 per cent. in the light-efficiency of the projector. The light-box, carrying the 4½-in. condenser and the lantern slide carrier, are separated by the cinematograph mechanism. Between the two pieces of apparatus is an objective formed of two achromatic lenses, the adjustment being such that the image of the condenser or of a plane a little in front of the condenser (that is to say the surface of a slide placed in the carrier) is formed exactly in the gate. In contact with the latter, in front of or behind the position of the film, a plano-convex lens is arranged, transmitting to the projection lens the rays which, without this addition, would diverge after passing through the gate. Under these conditions the whole of the light which passes the condenser is used for the projection of the picture. No adjustment is necessary when changing from cinematograph to ordinary projection. Lastly, when the apparatus is used for the projection of apparatus such as electroscopes, living specimens in tanks, etc., the image is projected on to the screen the right way up instead of being inverted as usual. It should be added that the whole apparatus resembles an astronomical telescope provided with a Dollond rectifier, the source of light occupying the same position relatively to the projection apparatus as the eye to this telescope.

A notable step forward has been made in the taking of high-speed cinematograph films by the G.V. camera made by the firm of A. Debrie, of Paris, from the designs of M. G. E. Labrely. Provided there has been great exactness in the perforation of the film (in which respect no latitude is permissible), this camera allows of taking up to 100 pictures per second when the handle is turned by hand at the normal speed, or up to 240 pictures per second with electric drive from a small battery. The camera can also be worked at normal speed, thus avoiding the cost and bulk of two separate outfits. The two film spools are contained in the same box, accommodating 400 ft. of film, a fresh box being fitted in five seconds. Inclusive of case, the weight of the camera is 29 lbs. The apparatus, which permits of prolonging the time of movement ten to fifteen times, has already rendered valuable scientific and industrial services in the analysis of rapid movements. Many of the cameras already constructed have been supplied to the United States.

M. L. Clement, a leading technical authority in the cellulose ether industry, has recently drawn up the report asked of him by the cinematograph section of the French Photographic Society on a ready method of comparing the qualities of films on different supports, that is to say a method which does not involve the chemical and mechanical tests employed by film makers, but is applicable by users and renters of film. The test for resistance which is proposed consists in making an endless loop of film about 2 yds. in length, consisting of equal lengths of the two films to be compared. These are cemented by their ends as perfectly as possible. The films, which should have been perforated of the same pitch on the same machine, and should also have undergone the same treatment as regards printing, development and drying. The loop is placed in an ordinary cinematograph projector, and is there arranged so as to receive a tension, by means of a roller mounted on a weighted lever, when the machine is put into normal operation. The motor of the projector is then put in action and an account kept of the number of times the band of film passes

round. This is done by making a mark on the band. Every five minutes the machine is stopped and the perforation examined, and the test is completed when all the perforations of one of the two pieces of film are distinctly affected. Examination of the different fractures is then made, with the exception of those close to the junctions in the film. The number of times which the film has to be passed round in order to produce this result varies from 200 to 300 according to the quality of the projector, and thus two bands of film on the same support may be compared or, alternatively, two projectors may be compared by using identical film bands in each. The various causes which contribute to changes in the film with time can be greatly accelerated by placing the film in a heated atmosphere, temperature playing very much the same part as time. A similar test may then be carried out on a band of two films which has been exposed for about 120 hours in an oven at a temperature of 140 deg. F. The degree to which a film resists this application of heat serves as a useful indication of its keeping qualities.

L. P. Clerc.

SPENT DEVELOPERS IN THE DESENSITISING OF PHOTOGRAPHIC PLATES.

In an article entitled "Desensitising Silver Bromide and Safranine Treatment." Dr. Lüppo-Cramer has recently stated (Zeitschrift f. angewandte Chemie, 1922, 35, 69) that the oxidation products of certain developers, such as amidol and its homologues, greatly diminish the sensitivity of silver bromide to light. Thus, development can be undertaken in bright yellow light, provided that the plate has been previously immersed in a bath of exhausted amidol developer.

It is also stated that ortho-chromatic and, with certain precautions, pan-chromatic plates can be developed in the same way.

Dr. Lüppo-Cramer gives but few details of the methods he employed. Apparently spent amidol of the usual strength was used, since it is stated that the desensitising bath contained 0.05 per cent. of oxidised amidol. Development was then conducted in bright yellow light of 5-candle power intensity, with a screen of Tartrazine or filter yellow.

The present writer has tested this process and experiments have been carried out to obtain suitable working details. The method certainly has considerable possibilities and quite good results have now been obtained.

For these experiments it was considered very essential to employ an amidol developer that was fully oxidised (exhausted) In order to make certain that the solution no longer possessed developing powers, a series of experiments were carried out to ascertain the exact amount of amidol required to convert a fixed quantity of exposed silver bromide into metallic silver. From quantitative experiments, it is now established that one gram molecule of silver bromide (188 grs.) is reduced to 108 grams of silver by one gram molecule of amidol (181 grs.).

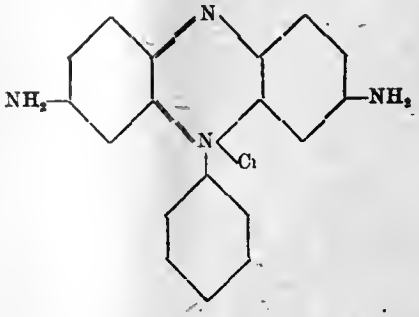
The oxidised amidol solution was therefore prepared by warming 500ccs. of ordinary amidol developer with six grams of freshly precipitated silver bromide, which had been previously washed free from other salts and then completely exposed to diffused daylight. The undecomposed excess of silver bromide and the metal formed were filtered off, and the filtrate was ready for use as a desensitiser.

In investigating the utility of Dr. Lüppo-Cramer's process, the exposed plates were immersed for ten minutes in the slightly warmed (21 deg. C. or 70 deg. F.) oxidised (spent) developer. They were then developed in the usual way. As soon as the plates were covered with the developing solution a bright yellow light was substituted for the red one employed up to this stage. The progress of development was observed, and the plates could be occasionally removed from the solution and held up to the light without the risk of "fogging." On one occasion diffused daylight was admitted into the dark-room during development, and no perceptible "fog" was detected afterwards.

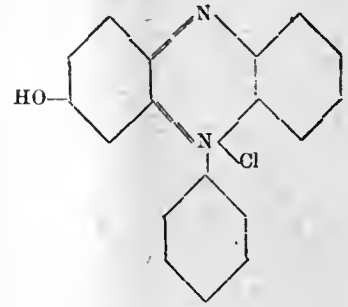
It was, of course, found that unoxidised amidol is not a desensitiser. Plates that were being developed in the usual manner "fogged" immediately on exposure to bright yellow light.

When this process is compared with the desensitising of silver bromide with safranin it is noticeable that the oxidised amidol solution is used in much greater strength, since safranin can be employed in as weak a solution as one part in two thousand of water. This solution is quite light red. The oxidised amidol solution is deep reddish brown.

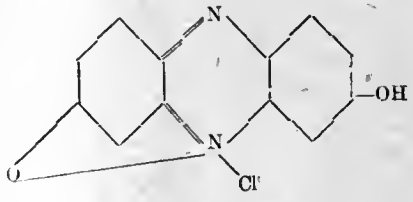
Presumably these substances function in a similar manner, although the presence of the accumulated potassium bromide, etc., in the spent developer must not be overlooked, since this restrainer may have some influence. Dr. Lüppo-Cramer is of opinion (*loc. cit.*) that it is the amino-group which plays an important part in desensitising the silver bromide. The formula for pheno-safranine is:—



If the amino-groups are replaced with oxygen or hydroxyl the safraninone (1) or safranol (2) so produced are found to possess no desensitising power.

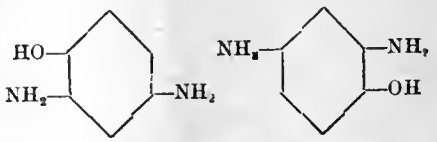


1.



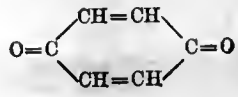
2.

The oxidation product or products of amidol have not yet been identified, but it is probable that an imino-quinone substance is formed. If the formulæ of two molecules of amidol base are written thus:—



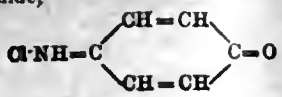
it will be seen that oxidation and condensation might give rise to a complex compound having a similar structure to that of safranin.

p-Phenylene diamine and *p*-amino-phenol (rodinal) may be regarded as homologues of amidol. When these substances are vigorously oxidised in acid solution they both yield quinone,



a deeply-coloured body which has now been found to possess no desensitising properties. Quinone is also the oxidation product of hydroquinone.

When p-aminophenol was carefully oxidised it first yielded quinone chloro-imide,



This substance readily oxidised further to quinone, but when acted upon by stannous chloride solution it was reconverted into p-amino-phenol.

The oxidation product of rodinal developer probably does not contain an amino-group. This conclusion has received strong support from the chemical evidence which has failed to indicate the presence of this radicle in spent rodinal developer. Thus the quinone chloro-imide would appear to be the active substance when oxidised rodinal developer acts as a desensitiser. This is not in agreement with Dr. Lüppo-Cramer's amino-group theory mentioned above. Further, the usual chemical tests have also failed to reveal the presence of an amino-group in completely oxidised amidol developer.

This negative evidence must not be considered sufficiently adequate to disprove Dr. Lüppo-Cramer's theory. The matter will be definitely decided when the exact constitution of the oxidised amidol has been determined.

J. G. F. Druce, M.Sc., A.I.C.

ELECTRIC CURRENT AT POWER RATE.

In the King's Bench Division on May 9 and 10, before Mr. Justice Swift, an action was brought by the Westminster Electric Supply Corporation, Ltd., of Eccleston Place, Westminster, S.W., against the Wykeham Studios, Ltd., 165, Victoria Street, Westminster, to recover a balance of account for electricity supplied to defendants. The case raised an interesting question as to whether current used for arc lamps in photographic businesses should be charged at lighting rate or power rate. Mr. W. S. Kennedy appeared for the plaintiffs (instructed by Fowler & Co.), and Mr. G. R. Blanco White represented defendants (instructed by Lickfold & Sons).

Mr. Kennedy, in opening the case, referred to the amount claimed, £82 18s. 5d., for the three periods, Midsummer, Michaelmas and Christmas, 1921, but defendants had admitted £48 5s. 10d., and paid this, so that only the small balance was in dispute. There was no dispute about the quantity of current, the sole question was as to the rate which plaintiffs were entitled to charge for current used by the arc lamp employed in the taking of photographs. The defendants' claim was that the charge should be the power rate. The plaintiffs' case was that they were fully entitled to charge rates up to the maximum on the schedule so long as no undue preference was shown.

The plaintiffs were authorised to carry on business under the Electric Lighting Orders Confirmation (No. 2) Act, 1889, which is in confirmation of a Provisional order made under the Electric Lighting Acts, 1882 and 1888. The Company was also governed by the London (Westminster and Kensington) Electric Supply Company's Act, 1908.

On July 26, 1913, the defendants entered into a contract to take a supply for certain lamps for lighting purposes and for a photographic arc lamp at 165, Victoria Street, which agreement provided for a lighting rate of 4½d. per Board of Trade unit, and for units used for photographic arc lamps at 1d. per unit, both the rates then current for light and power respectively. This arc lamp was on a separate circuit. In June, 1916, plaintiffs gave notice of alteration of terms of supply and submitted a new contract, which was signed by the defendants on September 28, 1916. This provided for a certain number of incandescent lamps for lighting as before, and one 50-ampere photographic arc lamp. The power rate was at the net rate of 1d per unit, but the lighting rate was raised. After 1916 there were continuous increases in costs of production, and early in 1921 plaintiffs gave three months' notice, expiring May 15 of that year, to terminate the agreement, and submitted a new contract for defendants to sign. This new contract provided for the studio arc being charged at the full lighting rate, which was then 8d. per unit as against the then power rate of 2d. This defendants did not sign, contending that they were entitled to have that portion of their current used solely for photographic purposes, and supplied through a separate meter, at power rates.

Mr. Kennedy said his submission broadly was that so long as the maximum in the schedule was not exceeded and the provisions of Section 19 and 20 of the Act of 1882 as to undue preference were not contravened, the charge was, so to speak, "at large." The limit was 8d. according to the schedule. There was no distinction in the Act as between electricity for lighting and for power, and by the agreement of 1916 the plaintiffs were entitled to vary the rates on giving not less than seven days' notice. Counsel mentioned that the matter of these charges had been discussed with the Professional Photographers' Association, and it had been agreed that the charge should be 4d. per unit, so it would appear that it could not be suggested that the plaintiffs were trying in any way to exact an exorbitant charge. In fact, 4d. was the charge plaintiffs were really seeking to make the defendants liable for. Counsel added that he did not suggest that this arc lamp was used for ordinary illuminating purposes. He submitted that if the company decided to charge 8d. for every unit supplied throughout the area no customer would have any remedy except on application to the Ministry of Transport.

Mr. Kennedy continued his arguments on behalf of the plaintiff company, quoting the decision in the case of the Attorney-General in Victoria v. Melbourne Corporation appeal case, 1907.

His Lordship: "You have one system of charging for lighting and another for power have you not?"

Mr. Kennedy said "No," the charge was a price per unit in each case.

His Lordship: "You say a division into lighting and power is not a differentiation?"

Mr. Kennedy said that was his contention, there could be no preference given, but it was only in the case of persons using the supply under similar conditions. There was no suggestion in the case that it was necessary to supply power at one rate and lighting at another. He said it was legitimate for the plaintiffs to charge different rates for power purposes. No suggestion was made in the defence that any undue preference had been given. The conditions that would follow from a decision that the power rate was to be the same in the case of every consumer would be very serious. He did not suggest that "the dreadful consequence" was one that would appeal to his Lordship, or that it would affect his construction of the Act of Parliament merely because serious consequences would arise, but such a construction of the Act as his friend was contending for would lead to a state of affairs never contemplated by the Legislature or anyone connected with the Act. If it was held that every consumer of power was to be supplied at the same rate which could not be altered, then the supply for power would cease, because it was impossible for any undertaking to supply a person using but a small amount for a short time at the same price that they would supply power to a railway company. As his Lordship was aware the question of the supply of power for the electrification of some of the railways round London was under consideration by the Ministry of Transport, and no railway with its large and continuous load would take power on these terms. Such a company would not pay a price like 4d. per unit, but would want it at 1½d or ¾d. It was impossible to supply a small man with one light and one motor at such a price as that.

Referring to the defendants' affidavit he said they claimed to continue the use of their arc lamp at power rates because they had hitherto been supplied at that rate. He did not admit it was power because it was charged for at power rates. No company had a power rate which they had not power to vary under the circumstances in which it was used. He did not know that he could complain of defendants' statement that the defendants had been using the light by a separate meter and at a lower rate. Naturally the company gave him a separate meter in the circumstances.

His Lordship: "Does it concern you to say that this is separate from the power rate supposing you have the right to fix your power rate according to circumstances?"

Mr. Kennedy did not think it did. If plaintiffs were entitled to vary the power rate then he was not concerned to deny that defendants were supplied for power.

His Lordship said on the facts he was inclined to think that this was current supplied for power purposes, and the plaintiffs' case was that it was a supply in which they had a right to differentiate as to the rate at which they charged. The defendants appeared to have assumed that there was no right to differentiate in the charges for power.

Mr. Blanco White said he did not wish to put his case higher than it was. The point was they might charge him the power rate

if they did not charge more than the maximum. That was what they were doing, he contended.

His Lordship: "Have they charged you more than the maximum rate!"

Mr. Blanco White said they had in his opinion.

His Lordship: "You are complaining of undue preference because they are charging you more than other users for power purposes, although somewhat less than the lighting rate?"

Mr. Blanco White said he contended that they were in the power class, and were entitled in these circumstances to be charged not more than the least favoured of the power users. What the company had done was to slightly alter their form of agreement for the supply of electric energy. They originally took the supply in 1916, which was terminated in 1921. Then plaintiffs charged at full lighting rate of 8d. to Michaelmas, 1921, when they entered into an agreement with the Association (who admitted it was not a power charge) to charge 4d. per unit. His clients were not parties to that agreement, and they said the charge for power was 2d. or 1½d. per unit, and as they were in the power class, they said they were being charged more than the maximum for power, in that they were asked to pay 4d. instead of 1½d. The power charge was originally 1d., but had gone up during the war.

His Lordship: "They were making a new class altogether?"

Mr. Blanco White said they had. The Photographers' Association admitted it was not power, and, in consideration of the admission, got a reduction, but the defendant was not bound by that, and, in consequence, the matter was now before his Lordship for determination.

His Lordship pointed out that the members of the Photographers' Association were paying a different figure than either light or power consumers.

Mr. Blanco White said that was so, and it was where the company got into the difficulty; they had made a special rate for photography.

His Lordship: "They have treated them not as a different class, but have created a new rate. There are now illuminating, power, and photographic rates."

In reply to his Lordship, Mr. Blanco White suggested that just because photographers used a photographic arc lamp, they wanted to get them into a class by themselves. He could show that in Westminster engineers' printers using the arc light for the purposes of producing their engineering blue prints were charged power rate.

Mr. Kennedy said there was no comparison between the two cases. The engineers used the light for hours at a time, while the ordinary photographer only used it from time to time at short intervals when taking a photograph.

Mr. Blanco White said he relied upon the plaintiffs' general advertisement that they supplied electricity for power purposes at 1½d. per unit. They had elected to supply power at 1½d. per unit and he was entitled to be supplied at that figure.

Mr. Kennedy admitted that the company offered to supply electricity for the purposes of power at 1½d. per unit, but it was a price adopted in some cases, but not in every case. In each case a special agreement was made. They were charging the defendants the same rate as every other consumer in the district who was using the current for the same purpose and under similar circumstances. The defendants had had an agreement previously subject to three months' notice to terminate, and also a seven days' notice, in accordance with the Act, to alter the rates, and these notices had been duly given by the company when they proposed to alter the rates. Unless the defendants went to the length of saying that a fixed sum must be paid by all power users the defendants must fail. There was no evidence of undue preference, neither did Mr. Blanco White suggest that his client was charged above the maximum, which was 8d. In these circumstances, he said, the company were justified in charging defendant 4d. per unit.

Mr. Blanco White having stated that he had experts present relative to evidence on wave lengths and blue-print photographers, radiator users on the plaintiffs' circuits, if his Lordship should consider it necessary for him to proceed further,

His Lordship said the case raised what might be important points in connection with the supply of electricity, and he would reserve his judgment. It had been ably argued on both sides by counsel, from whom he had received great assistance.

The services of Mr. J. C. Elvey, A.M.I.E.E., etc., consulting electrical engineer, were retained by defendants in the preparation of the case.

GERMAN SCIENTIFIC GOODS.

Board of Trade Inquiry Committee.

The first meeting of the Committee of Inquiry set up by the Board of Trade to take evidence and report on the sale of optical and other scientific instruments manufactured in Germany took place at the Hotel Windsor (Mines Department) on May 15. The Committee, as already announced in these columns, consists of Sir R. Henry Rew, K.C.B. (chairman), Mr. A. K. Davies, Mr. Rayner Goddard, Mr. A. E. Holmes, and Mr. J. F. Mason, J.P., with Mr. T. Turner, secretary. The Committee is instructed to report to the President of the Board of Trade:—

(1) Whether the conditions specified in Section 2, Sub-section (1), of the Safeguarding of Industries Act, 1921, are fulfilled in respect of all or any particular varieties of optical and other scientific instruments;

(2) On the effect which the imposition of a duty under Part II. of the Act on goods of the class or description covered by the complaint would exert on employment in any other industry being an industry using goods of that class or description as material; and

(3) Whether in the opinion of the Committee production in the industry manufacturing similar goods in the United Kingdom is being carried on with reasonable efficiency and economy.

The complaint is brought by the British Optical Instrument Manufacturers' Association, Ltd., the British Photographic Manufacturers' Association, the Spectacle Manufacturers' Association, and the Drawing Instrument Manufacturers' Association, and is to the effect that optical and other scientific instruments manufactured in Germany are being sold or offered for sale in the United Kingdom at prices which, by reason of depreciation in value in relation to sterling of German currency, are below the prices at which similar goods can be profitably manufactured in the United Kingdom, and that by reason thereof employment in the industry manufacturing similar goods in the United Kingdom is being, or is likely to be, seriously affected.

At the opening of the inquiry the Chairman called upon Sir Arthur Colefax to submit the case for the applicants and to tender evidence.

Sir Arthur Colefax said that he appeared, with Mr. Stafford Cripps, for the four associations named. He explained the nature of the complaint. The applicants intended to concentrate their case upon a few standard articles which were typical, these including cameras and lenses. After referring to German-made prisms and binoculars, which were sold at something like one-third of the cost of the similar British-made articles, Sir Arthur said that figures as to the cost of manufacture would be given, but it was requested that they should not be made public. He went on to speak of microscopes. British-made microscopes were considered to be superior to anything made elsewhere, but they were absolutely unable to compete with German goods in view of the low prices of these latter. With regard to photographic cameras and lenses, here in respect of cameras British manufacture was at one time supreme, and with regard to lenses, lost ground was being regained at the outbreak of the war. German competition in lenses had been very keen, and had been animated, it was believed, by an ambition to kill the industry in this country, but British enterprise went on maintaining its position. During the war there was an enormous extension of the manufacture of all kinds of lenses, and British manufacturers were in a position to take advantage of the demand. Almost directly after the war came to an end, however, importers began buying cameras in Germany, and selling them here at prices which were little, if at all, in excess of the actual cost of the material, quite apart from the cost of the labour. Sir Arthur then went on to refer to cheap German spectacles. With regard to unemployment generally, manufacturers of cameras and microscopes would state that they were employing less than half the number of workpeople they employed in 1913. It was recognised that this was a period of trade depression, but the opinion of the complainants was that this industry was one not directly affected to the same extent as other industries by bad trade. Sir Arthur concluded by urging that the 33⅓ per cent. duty imposed was insufficient under the circumstances.

At this point it appeared that the application was opposed, but the Chairman said that no notice of opposition had been given.

Mr. Ernest Evans, M.P., said that he was instructed by Messrs. Stikeman and Co. to appear on behalf of a group of merchants and importers. He undertook to give the formal notice which was required.

EVIDENCE.

Mr. Conrad Beck, managing director of R. and J. Beck and Co., optical and scientific instrument manufacturers, was the first witness. His evidence specially related to the sale of microscopes. He produced for the Committee's inspection English-made and German-made instruments, and gave details of the prices. He said that if it was a question of a small amount, they would not ask for protection, but the low price of the German article prevented trade. He gave figures showing the reduction in the number of men employed in his firm since the war. Ordinarily between 2,000 and 3,000 microscopes should be sold each year, and in normal times there was a steady demand. The largest trade was done among medical students, every one of whom should have a microscope. In reply to a question from the Committee, the witness agreed that certain German microscopes, for which about £13 was charged, could not be said seriously to be competing with a first-class English instrument.

The Committee adjourned until Tuesday morning, when the first witness to be called was Mr. Watson Baker, representing W. Watson and Sons, makers of prism binoculars.

When the committee met on Tuesday, the chairman announced that it was proposed to hear as many witnesses as possible that day, and then adjourn to May 31.

Mr. Cripps (for the applicants) asked if Mr. Evans, who had been instructed to object to the application, would indicate the line which would be taken by the opposition. At present the committee was only dealing with five typical cases, but the opposition might bring something else forward.

Mr. Evans undertook to make a statement at a later stage.

Mr. A. Dennis, B.Sc., Works Director, Houghton-Butcher Manufacturing Co., Ltd., of London, was the next witness. He said that his firm made all kinds of cameras and photographic apparatus. During the war the factory was practically completely employed on making special apparatus for the Army and Navy, particularly in connection with aeronautics. Houghtons, Ltd., which had been established for 50 years, owned that factory before the war. The total sales now were about half of those of Houghtons, Ltd., in 1914, although exactly similar cameras were being made. In 1919, before the competition from Germany materialised, there was a great demand for the output of the factory—so great that it was scarcely possible to meet it. A big export business was done formerly, but now the exports were limited practically to one country, namely, Japan. The export trade was only 20 per cent. of what it was in pre-war days. Before the war there were exports to Scandinavia, Italy, and France, but trade had fallen off considerably in those countries, and in Scandinavia, owing to German competition, it had disappeared almost completely.

Asked by the committee how many people were employed in the manufacture of photographic apparatus in this country, witness said that the number was about 20,000, but this included those employed by the manufacturers of sensitized material. He had no definite figures, but the actual number, after making a deduction on account of the employees of plate and film-making firms, might be somewhere about 13,000. He went on to give some details as to the number of persons employed by his own firm, and the reduction which had taken place since 1920; also particulars as to the hours worked per week. In 1913 the working week was 55 hours; in 1920, it was 47. In 1921 80 per cent. of the people employed were working a reduced week of 34 hours. Matters had improved since then, and now 60 per cent. were working the 47-hour week. But in 1913 the whole of the employees, then numbering 855, worked 55 hours.

If the present application succeeded it would have considerable effect on employment. The most formidable German competition was in plate cameras. It was practically impossible to sell an English plate camera, except to a man who was determined to have the English article. The German cameras were not by any means made according to the best methods, and the German plant was not as good as the plant in this country. With fair competition, therefore, it would be possible for British manufacturers to beat Germany hollow in any market in the world. The witness handed to the committee catalogues and lists showing the low cost at which the German cameras were sold. In reply to a member of the committee, he agreed that the present was a period of trade depression, but that was no reason for accepting a position in which the 1922 trade was less than half the 1913 trade. There was good reason to believe that people were prepared to spend money freely on cameras at the present time. The average amateur, especially the beginner, took his film to the nearest chemist to be developed, and the number of spools developed per day had increased fourfold of recent years. That was an indication that there were more cameras in use than ever. Witness would not suggest that the protection sought would eliminate competition, but it would at least offer British manufacturers a sporting chance. They would stand by their goods, and by the organisation that produced them, but they could not face the conditions which obtained at present. Asked why the export trade with Japan had been so well maintained, the witness said that Japan bought the highest class of instrument. It was an expensive camera, but it was being sold in Japan in considerable quantities, more so than before the war.

In reply to Mr. Holmes, who asked if the Germans were putting forward a popular line in plate cameras, the witness said that the plate camera was going out, and the sales every year were less. The amateur who simply wanted to get pictures and did not trouble much about the scientific side of his pursuit, preferred a film camera. Plate cameras, both German and English, were now being fitted to take films. In reply to a question as to the fall in wages and the price of cameras, the witness said that his firm had made all possible reductions in price.

The remainder of the morning was occupied with the evidence of makers of lenses for ophthalmic purposes and of field-glasses.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications May 1 to 6:—

COLOUR PHOTOGRAPHY.—No. 12,618. Colour photography. A. R. Trist.

MAPS FROM PHOTOGRAPHS.—No. 12,398. Photogeodetical production of maps from photographs. M. Gasser.

FILMS.—No. 12,377. Printing photographic films. H. V. Lawley.

FILMS.—No. 12,612. Manufacture of photographic films. Pathé Exchange, Inc.

COLOUR CINEMATOGRAPHY.—No. 12,408. Optical devices for vision or projection of films in colours. A. Keller-Dorian.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

REPRODUCTIONS OF PICTURES ON CURVED SURFACES.—No. 166,513 (July 15, 1920). To enable the pictures drawn on curved surfaces of Grecian vases, which are the only relics of Grecian

FIG. 1.

painting of the classical epoch, to be manifolded by photography, many attempts have been made.

The invention enables curved pictures to be reproduced on plane surfaces with the aid of simple means and at small cost.

Assuming, at first, that only cylindrical or conical surfaces, i.e., envivable surfaces, are to be dealt with, the invention consists in the curved surface being photographed in the ordinary

way, and in then projecting the negative obtained on to sensitive paper wound round a body of the same shape as the curved surface. If the photograph is to be of the same size as the original the body round which the sensitive paper is wound must have exactly the same size as the original body and it must be placed in exactly the same position, and, if the focal lengths of the taking objective and the projecting lens are equal, the distances between the body and the

Fig. 2.

objective on the one hand and between the objective and the negative on the other hand must be the same as the distance between the original body and the objective on the one hand and between the objective and the photographic plate on the other hand. If the scale of the drawing is to be different, the body on which the sensitive paper is wound must be similar in shape to the original body, but it must be correspondingly larger or smaller in size and the distances must be altered accordingly. The process may also be employed for original surfaces curved

Fig. 3.

in two directions, if the curvature in the vertical direction of the body is not excessive. In such cases the body round which the sensitive paper is wound must not be congruous to the original, but must have an evolvable surface which is the particular cylindrical or conical surface that is most nearly similar to that of the original body.

In the drawings, the part *a* to be taken of the Grecian vase selected by way of example has a surface which is slightly

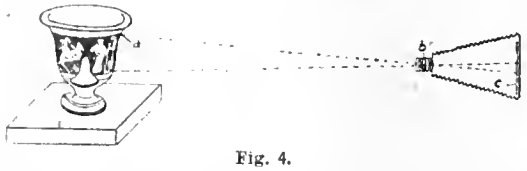


Fig. 4.

concave and tapers toward the bottom. A photographic camera with lens *b* has a sensitive plate *c* placed opposite the surface *a* to be taken. The taking camera is preferably placed at a sufficient distance from the object to get its receding portions as well as its prominent portions sufficiently distinct. The reproduction of the photograph taken is accomplished as follows :—A body *d* is made whose size is the same and whose shape is practically similar to that of the original body. Thus in the

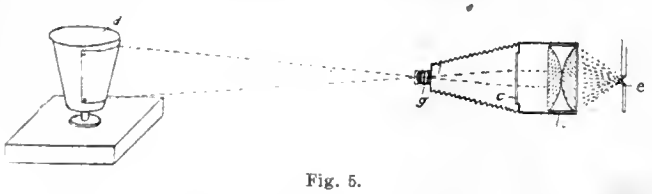

Fig. 5.

example illustrated, instead of a body that is slightly concave like the original, a body with a conical surface, has had to be used. In the reproducing apparatus the negative *c* is illuminated through the condenser *f* by the light *e* and projected through the lens *g* on to the surface of the body *d* round which a sheet of sensitive paper is wound.—Dr. Gottfried von Lücken, 26, Magdeburger Strasse, Berlin.

The following complete specifications are open to public inspection before acceptance :—

Etching Process.—No. 179,137. Process and apparatus for electrical etching. Weeks Photo-Engraving Co., Inc.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Stands Above All (Stork Design).—No. 421,936. Photographic apparatus included in Class 8 made in Great Britain. William Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4., manufacturers. December 31, 1921.

Stands Above All (Stork Design).—No. 421,937. Photographic papers, mounts and albums included in Class 39 and made in Great Britain. William Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4, manufacturers. December 31, 1921.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

Kosmos.—No. 417,223. Photographic plates and films and chemical substances prepared for use in photography. Kosmos Photographics, Ltd., Balfour House, Finsbury Pavement, London E.C.2, manufacturers of photographic papers, plates and apparatus.

Carbine (Stork Design).—No. 421,863. Sensitised films for use in photography. William Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4, manufacturers.

New Books.

The Wellington Handbook.—We welcome the appearance on our table of the twelfth edition of this handbook, by which for many years past Messrs. Wellington and Ward have provided photographers with sound instruction in the ordinary processes of negative making and printing. The text follows the excellently practical lines of previous editions and has an additional introductory chapter, specially addressed to the beginner, on the choice of a camera. There is also a fresh chapter on the Bromoil process, in which detailed instruction in the making of Bromoil and Bromoil transfer prints is given. The handbook also contains the working instructions for the new Wellington Q-Tone paper for prints of warm black colour by direct development either with metol-hydroquinone or with the special M.Q. developer containing borax. For the present edition the publishers have provided a dozen supplemental plates in photogravure from negatives on Wellington Anti-Screen, 'Xtreme and 'Xtra Speedy plates, which admirably convey the high quality of these products. The handbook is issued at the price of 1s. net in handsome cloth binding. It must cost considerably more than this sum to produce.

Registration of Business Names.—The Board of Trade have appointed Mr. Henry Birtles, the Registrar of Joint Stock Companies, and Mr. Arthur Edwin Campbell-Taylor, O.B.E., the Assistant Registrar of Joint Stock Companies, to be Registrar and Assistant Registrar of Business Names respectively.

Copyright in Brazil and Hungary.—In consequence of the accession of Brazil and Hungary to the revised Berne Copyright Convention of 1908, Orders in Council were made on April 21, 1922, under Section 29 of the Copyright Act, 1911, extending the provisions of the Act to Brazilian and Hungarian authors and works. Copies of the Orders may be seen in the Patent Office Library, 25, Southampton Buildings, W.C.2.

New Materials.

Imperial Desensitising Backing. Made by the Imperial Dry Plate Co., Cricklewood, London, N.W.2.

THE IMPERIAL CO. send us a packet of their plates backed with a new D-S backing which they have recently introduced, the title signifying that the backing also acts as a desensitiser of the plate when the latter is placed in the developer. The backing consists of a tough reddish coating, applied in liberal quantity, which we find to be highly resistant to friction or to any abrasion likely to cause a more brittle coating to chip off. But in the case of the D-S backing it is impossible to scratch it off with the finger nail; in fact, even with the use of the blade of a penknife or a sharp point it is not the easiest matter to remove it. Nevertheless, within a minute or so of immersion in the developer the entire coating dissolves away completely, giving a reddish colour to the developing solution. From trial of the plates which we have used, the Imperial ultra-rapid Eclipse, we can fully confirm the claims of the makers as regards the twofold properties of the backing, anti-halation and desensitising. The backing forms a powerful absorbent of the light passing through the plate, and is an extremely efficient preventive of halation. The desensitising dye which enters into its composition permits of development being done in moderate white light after a minute or so has elapsed for the backing to dissolve in the developing solution. Those who habitually work in a dark room will, of course, use the ordinary safe illumination during this first minute, and may then complete development in a much brighter light. It is, of course, inadvisable to take liberties with the reduced sensitiveness of the desensitised plate. It will not do to continue development in the bright light of an ordinary room or within a foot or two of an electric lamp but the boon which the backing confers of developing plates in about the same degree of illumination as is safe for, say, gaslight papers, will be appreciated by everyone who has many plates to develop. Moreover, the amateur worker unequipped with a proper dark room may employ a changing bag or box for the application of the developer, and then after a minute or so remove the dish from this shelter and finish his work in a light of the order of safety which we have just indicated. There is no doubt that this incorporation of a desensitising dye with an anti halation coating, in which the Imperial Company have led the way, will be widely welcomed by all classes of photographers as a further step towards the abolition of the dim light which hitherto has been necessary for the development of sensitive plates.

New Apparatus.

The Apem Vignetter. Made by Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1.

WHILE there have been in the past a fair number of patterns of holders for negative-making vignetting cards, we do not think there has been one which so fully fulfils every requirement as the present apparatus. It is indeed difficult to imagine that in range of movements and mechanical workmanship manufacture of this studio appliance can go further. The holder consists of a metal tube 27 inches in length, which is mounted on a stout metal quadrant so that it can be tilted up or down at about this midway point. To one end of the tube is fitted the square rod on which slide the two parts of the vignetting card. The other end, that placed at the rear of the camera, carries the two milled discs and the milled handle-piece by which the movements of the cards are controlled. The whole appliance can be fitted on either side of the camera stand, for operation by the left or the right hand, as most convenient.

As illustrated in the drawing, and particularly in the two smaller diagrams of the apparatus, the smaller milled disc operates the angling of the vignetting cards. This movement is made by a positive worm connection between a rod running the length of the tube and that on which the cards are mounted. The larger milled head operates the spread of the two parts of the vignetter. This is done by the turning a grooved wheel at the forward end, a catgut band being arranged to give a travel of each part of the vignetting card in opposite directions. The milled handle, shown best in the largest of the three illustrations, turns the whole tube so as to move the rod which carries the cards in a plane parallel to that of the plate—that is to say, this movement puts the vignetter more or less skew-wise, though still parallel, to the plate, and thus provides for vignetting a subject more or less diagonally towards one corner or another of the negative.

The fourth movement is twofold. By loosening the winged nut which normally clamps the tube against the supporting quadrant,

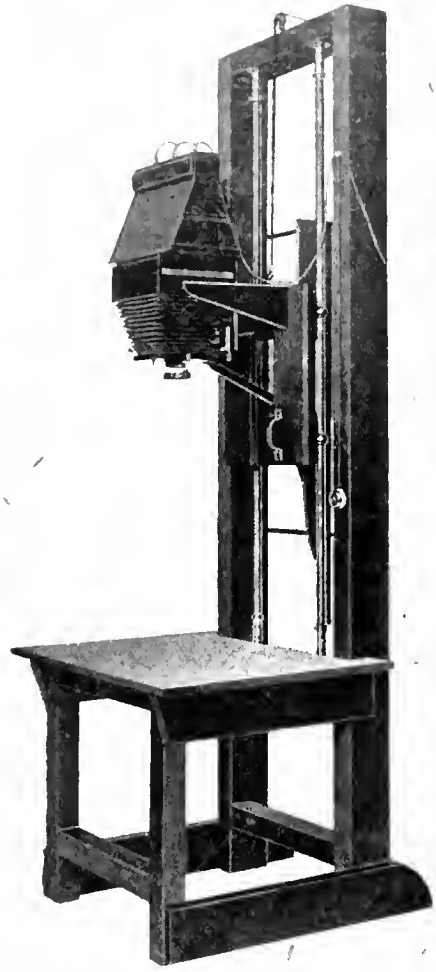
the tube is released for sliding to and fro, and also for raising or lowering the vignetting card, by turning the tube as a whole upon the axis by which it is secured to the quadrant. It will thus be seen that the apparatus most comprehensively includes all the movements which can conceivably be required of a vignetter, and, moreover, allows of these being made with the utmost convenience, and whilst viewing the effect of adjustments upon the image on the focussing screen. It seems impossible that the studio portraitist can ask for more. The apparatus is exceedingly well made in nickelled and blacked metal, and is supplied price £2 17s. 6d.

High-Power Focussing Magnifiers. Made by J. H. Dallmeyer, Ltd., Carlton House, 11d, Regent Street, London, S.W.1

MESSRS. DALLMEYER send us one of the focussing magnifiers which they have recently introduced, and which we find to be an excellent instrument having a magnification of about ten times and a wide field of achromatic definition. The magnifier is mounted in a brass sleeve provided with a screwed collar by which the glasses can be set and kept at the distance from the plane of the object suitable for individual eyesight. The range of movement which is provided for this purpose is three-quarters of an inch. The magnifier is of 1¼ inch diameter and 1½ inches in length when closed. It is supplied price £2.

The Overton Automatic Focussing Enlarger. Sold by O. Siehel and Samuelson, 52, Bunhill Row, London, E.C.1.

This apparatus, which was shown at the recent Photographic Fair, provides the great facility for automatic focussing in making enlargements with the added one of reducing, the latter by disengagement of the automatic device and employment of a hand method of focussing. For automatic work the range of enlargement is from 1½ times to about 6 times, that is to say, enlargements of from 7½ x 5½ inches to 36 x 30 inches when working from a half-plate negative. Half-plate is the largest size of negative which the apparatus takes for enlargement of the whole subject, but the negative stage is so arranged that negatives up to whole-plate in size may be enlarged



The framework and bench of the apparatus is extremely well made, the camera sliding very sweetly on solid steel uprights. By the use of a counterweight the camera is very easily moved, remaining in any given position. The mechanism which automatically adjusts the movement of the lens in relation to the negative in accordance with the degree of enlargement is of a very simple kind, and, as we were able to see from the apparatus at the Fair, accurately keeps the enlargement in focus without any sacrifice of sharpness.

Illumination is by three 100-watt Ediswan Fullolite lamps contained in the sloping chamber seen in the photograph. The bellows has an extension of 24 inches, a length which, with the 7-inch Ross *f*/6.3 Homocentric which is fitted, allows of a considerable degree of reduction when this description of work requires to be done, as in making lantern-slides or copy transparencies from negatives. The floor space required for the apparatus is 4 ft. by 3 ft., and the overall height is 9 ft. The price of the complete outfit is £50.

How the Royal Wedding Presents were Photographed.—The much-talked-of and much-queued-for wedding presents have been photographed, and the "Evening News" tells how the work was done. The producer of the film was Mr. Denison Clift, an American; the lighting experts were French; Mr. Belbuoni, an Italian, was the camera operator; and the rest of the staff of nearly twenty people were British. As there were only about twenty-four hours to spare between the public exhibition of the presents and their removal from St. James's Palace, the job had to be carried out very speedily. Certain permissions had to be obtained to take photographs in the Palace, and a direct order from the King was required to remove the difficulties. The photography of individual pieces of jewellery took four hours, but the work must be worth while as the film will be a unique contribution to British history records. Princess Mary and Viscount Lascelles took a keen interest in the film, and for some time followed the camera from room to room.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SUNDAY, MAY 21.

Hammersmith Hampshire House P.S. Outing to Aldenham.

MONDAY, MAY 22.

City of London and Cripplegate P.S. General Meeting.
Southampton Camera Club. "Chromatics." W. R. Kay.
South Glasgow C.C. Outing to Logan's Well.

TUESDAY, MAY 23.

R.P.S.—Technical meeting under the control of the Scientific and Technical Group. (1) Spectroscopic measurements of the hydrogen ion concentration colour changes in recent indicators, by Leslie F. Davidson, B.Sc.; (2) The dyeing of Silver Iodide with Methylene Blue, by K. C. D. Hickman, B.Sc.; (3) The function of the flash exposure in three-colour work, by E. L. Turner and C. D. Hallam; (4) The Trist three-colour exposure camera, by A. C. Banfield.
Bournemouth Camera Club. Criticism Evening
Cambridge Phot. Club. Exhibition of Winter Competition Prints.
Hackney P.S. "In the Land of the Fells." J. Grice.
Manchester Amateur Phot. Soc. "The Way of the Lovely Sky." A. G. Buckham.

WEDNESDAY, MAY 24.

Croydon Camera Club. "The Evolution of the Hand Camera." A. S. Newman.
Exeter Camera Club. Outing to Shobrook Park.
Hackney P.S. Outing—Westminster to Battersea.
Partick Camera Club. Print Criticism.

Partick Camera Club. Outing to Kilbarchan.
Sheffield Phot. Soc. Outing to Dukeries.
Wallasey A.P.S. Outing to Bidston Hill and Village

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, May 16, the president, Mr. W. L. F. Wastell, in the chair.

Mr. J. F. Shepherd read a paper on "Natural Colour Photography," in which he described the process to which he had given the name Triadochrome. He laid stress upon the correct relative exposure of the three colour-sensation negatives, without the proper balance of which the making of a correct colour print was impossible. In making a Triadochrome paper print from a set of negatives, prints on Transferotype bromide paper were made from the blue-sensation and red-sensation negatives. That from the former was toned yellow, and the other blue, by the ferric iron process. From the green-sensation negative a red pigment print was made on celluloid, and the blue and then the yellow prints successively transferred to it. A paper backing was then applied, and the composite three-colour print transferred to it.

A number of prints by the process were passed round, and aroused a good deal of discussion, the chairman expressing the opinion that the difficulties of making prints by the superimposition of three-colour images were insuperable, and were illustrated in the specimens shown. At the same time he acknowledged the success obtained by Mr. Shepherd within the limits of the process, and proposed a vote of thanks to the lecturer, which was passed by acclamation.

A demonstration was then given by Mr. Traise, of Messrs. Jonathan Fallowfield, Ltd., of a daylight projection screen consisting of ground glass placed ground side towards the audience, the lantern being placed behind. A remarkably bright picture was produced, even with Autochromes, by means of a lantern fitted with an 800-c.p. half-watt lamp. The projection required to be viewed from positions such that the line of vision of the observer formed a fairly small angle with a line at right angles to the screen.

If the position lay much to one side or the other, the picture suffered in brightness. The outfit, however, served excellently for the exhibition of slides in full daylight to small audiences, and the lamp possessed the advantage of being run from any house circuit.

A hearty vote of thanks was accorded to Messrs. Fallowfield and Mr. Traise.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council took place at 35, Russell Square, on May 12, 1922. Present: Messrs. Marcus Adams, Angus Basil, A. Bennett, W. B. Chaplin, H. A. L. Chapman, Gordon Chase, A. Corbett, W. E. Gray, Reginald Haines, H. A. St. George, George Hana, F. G. Wakefield, W. H. Wedlake, and Halksworth Wheeler, with Alfred Ellis (Secretary) and J. A. Griffiths (Editor). Mr. Alexander Corbett in the chair.

Apologies for absence were read from Messrs. Swan Watson (President), R. N. Speaight (Treasurer), C. F. Dickinson, W. Illingworth, Herbert Lambert and F. Read.

Arising out of the minutes, the secretary read further correspondence in a case in which the proprietors of a small journal disputed liability to pay for the reproduction of a photograph. The matter was left in the hands of the secretary to deal with further. He also reported interviews which he had had with the art editors of two daily illustrated papers concerning reproductions.

The chairman reported on the case of Westminster Electrical Corporation v. Wykeham Studios, in which the judge had deferred his decision.

Mr. Hana read the report of the Propaganda Committee, with regard to which a good deal of preliminary work has been done.

Mr. Marcus Adams brought forward a suggestion by Mr. Barrett that a competition should be organised in connection with the congress for photographs of the best dressed photographer's window or show-case, the photographs in question to be exhibited at the congress. It was left to Mr. Wedlake, on Mr. Haines' proposition, to look into the matter and report to the next meeting of Council.

Mr. Wakefield presented a report on the progress of arrangements for the trade exhibition in connection with the congress. He had had a large number of inquiries as to space and terms.

Mr. Haines raised the question of the admission of the public, and the secretary said the decision of the Council was that the public should be admitted to the trade and photographic exhibition between the hours of 10 and 5.

The chairman said that in Mr. Wakefield's next letter to intending exhibitors it should be made clear that the exhibition would be open to the public. Mr. Wakefield agreed.

Mr. Adams reported with regard to the Foreign Loan Exhibition, that an interesting letter had been received from Mr. Pirie Macdonald, who was doing his utmost to get a fine collection together, as were Mr. Bridgeman, of Vancouver, and others.

Other correspondence related to a dispute over the ownership of negatives, and the Council endorsed the advice which the secretary had tendered to the appealing party.

One member had written about some dry plates which were defective, and one of the Council offered to test and report upon an unopened packet, which the secretary had asked the member concerned to forward.

A member wrote from Lucknow asking advice with regard to the planning of a studio, and the secretary had sent him particulars as to architects and literature, and also a sketch plan of his own.

Advice had also been given to members on insurance policies, the taking out of county court summonses, and in respect to various complaints.

A member having written to ask for a scale of prices for commercial work, Mr. Haines suggested that every member of the Council should be asked to send to the Propaganda Committee his own idea of the scale of charges, which the committee could thereupon average.

Mr. Hana undertook to send out a schedule which members of Council could fill in. It was understood that the prices set down would be those actually realised by the member concerned.

Four applications for membership were considered:—H. Connold, London; C. D. Geddes, Perth; W. Thomas, London; D. Went, Brightlingsea. All were found to be in order.

Mr. Adams made a statement on the Faculty of Arts, which was intended to represent an assembly of everything artistic, and which desired for its photocraft group the support of the Association. The Faculty was anxious that every photographer should become a member of the group, they were now making licentiates, who, in future, would be referred to the group to which they belonged. The group ought to be representative of the Association, the Royal Photographic Society and the London Salon. He added that the Faculty was incorporated last November, and he promised to bring forward a more considered statement on the subject at the next meeting.

Mr. Basil supplemented Mr. Adams' statement. Further consideration of the matter was adjourned until the next meeting.

Mr. Gray initiated an informal discussion on railway rates for photographic luggage, and described recent experiences of his own. He promised that when the matter at issue between himself and the railway company was advanced to a further stage, he would bring it before the Council in a concise form.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice of intended dividend is given in the case of James Alfred Derbyshire, artist, photographer and cinematographer, residing at 1, Joldrell Street, Newtown, New Mills, and carrying on business at Goyt Studio, New Mills. Proofs must be lodged on or before June 2, with Archibald Yearsley, 27, Brazennose Street, Manchester.

EASTMAN KODAK COMPANY.—The directors have declared quarterly dividends of 1¾ per cent (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock; and of $1.25 per share of no par value of common stock, payable on July 1 to stockholders of record on May 31.

NEW COMPANIES.

BRITISH DEKO SYNDICATE, LTD.—This private company was registered on May 9 with a capital of £5,000 in £1 shares. Objects: To carry on the business of photographers, producers of pictorial photography, etc., and to adopt a certain agreement, the parties to which are not named. The subscribers (each with one share) are:—E. McBean, 89, Drakefield Road, Brockley, S.E., clerk; W. T. Lock, 3, Winterwell Road, Brixton Hill, S.W., assistant secretary. The subscribers are to appoint the first directors. Secretary: E. McBean. Registered office: 87, Moorgate, E.C.

W. K. SIMPSON & CO., LTD.—This private company was registered on May 9 with a capital of £2,000 in £1 shares. Objects: To carry on the business of manufacturers of and dealers in optical, surveying, nautical, astronomical and scientific instruments of all kinds, chemical and photographic apparatus, etc. The first directors are:—W. K. Simpson, 38, Goddard Avenue, Hull, optician; F. J. Milestone, 7, Marlborough Avenue, Hull, chemical manufacturer. Qualification: 100 shares. Registered office: 38, Goddard Avenue, Hull.

News and Notes.

PHOTOGRAPHIC PITCHES AT HASTINGS.—At the letting of sites on the beach at Hastings last week £1,800 was obtained. The photographic pitches fetched £97.

HEADSTONE PHOTOGRAPHS.—Photographs "blown into glass" and let into grave headstones are now becoming common in American cemeteries, says a news item.

REGISTRATION OF BUSINESS NAMES.—It was stated in a reply given in the House of Commons last week that the number of business men registered under the Registration of Firms Act was 152,335. Fees received amounted to £5,502 15s. 6d. for the year, and expenses £8,900 11s. 7d. It was proposed to increase the registration fees.

DEVELOPING AND PRINTING.—Messrs. W. Butcher & Sons, Camera House, Farringdon Avenue, London, E.C.4, announce a developing, printing and enlarging service for the amateur film trade. A price list of charges for circulation among dealers' customers is obtainable and can be had with the name and address of the dealer printed thereon. A special wallet for the supply of negatives and prints has been designed. Messrs. Butcher will send full particulars of this service to dealers and others interested in the D. and P. business.

PHOTOGRAPHING WASPS.—Mr. F. Martin Duncan, lecturing before the London Zoological Society last week, showed upon the screen a "close up" picture of a wasp's head which filled the entire screen. Another picture showed a wasp eating honey from the back of a lady's hand. Wasps, said Mr. Martin Duncan, were perfectly harmless, and made no attempt to sting if you were quiet and gentle in your movements. All his photographs, which also included studies of wasps building their comb and of young wasps being hatched from their cells, were obtained without a single sting.

A 500 EXPOSURE CAMERA.—According to the "Newcastle Chronicle" a camera has been invented which will take photographs or films, develop them, fix and chemically dry them—all inside 120 seconds. Mr. E. B. Hayes Fratze, who is closely connected with the invention, has stated that the new camera is slightly larger than the ordinary autographic camera, and the whole thing is worked by a secret chemical process. The camera and contents are practically indestructible, and 500 to 1,000 pictures can be taken without renewing the contents. It is hoped to put the camera on the market at a competitive price, and also to make it exclusively a British product.

A NEW PRESS-PHOTOGRAPHY RECORD.—Rush in Press photography is common enough to-day, but the greatest rush of all was that of getting into the London morning newspapers of the 9th inst. reproductions of photographs of the arrival of King George V. and Queen Mary in Brussels on the previous evening. Photographs of the King's arrival were taken by a Press photographer at 5.22 p.m. at Brussels, and the undeveloped plates were rushed to Evere aerodrome, just outside the city, where they were put on board an aeroplane. A motor-car was waiting at Croydon aerodrome to convey the plates to the London newspaper office. There was also a motor-car waiting at Lympne aerodrome, Kent, in case the aeroplane coming from Brussels was compelled to make a forced landing. The aeroplane started at 5.40 p.m., and arrived at Croydon at 8 p.m., covering 202 miles in 1 hour and 55 minutes, and travelling at an average speed of over 105 miles an hour. The plates reached the London offices at 8.40 p.m. Never before, we believe, have photographs taken in a foreign country at such a late hour been published in a London morning newspaper on the following day. This in itself is a great feat; but, in addition, it was arranged that the special edition containing these photographs, with their titles printed both in French and English, and the description of the arrival also printed in both languages, should be sent off by aeroplane to Brussels very early in the morning.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

D. W.—If you write to Messrs. Winsor & Newton, 37-40, Rathbone Place, London, W.1, they will send you a reprint of a very good article on colouring lantern slides, for which work they supply the best colours and brushes.

B. J.—Yes, the postcard is printed from a half-tone block. Messrs. Hood & Co., Sanbride Works, Middlesbrough, or Messrs. Hamel & Co., Premier Studios, Palmerston Street, Woodborough Road, Nottingham, supply blocks of this kind.

R. K.—We have no experience in the use of Arctic glass for studio glazing, but provided that it is not of a decidedly green or yellow tint it should answer very well. It is more usual to employ "rolled plate," which we think would diffuse the light more evenly.

S. H.—Effect of sulphur toning is somewhat uncertain, that is to say, it works well with some papers and not with others. We advise you to take the advice of the makers of the sensitive cards which you will be using. About the average formula is that in the Almanac.

M. H.—Two and a half years is a long time for keeping bromide paper under ordinary conditions of storage. We do not suppose there is any ground for thinking the paper was originally defective, and we do not think that there is anything which you can now do to render it perfect for use.

W. H.—If you mean that you should follow up the matter by taking any kind of legal action, we advise you to think nothing more about it. The issue is very doubtful. Most probably the judge would say that it was a matter which was not of sufficient importance to be brought before the Court.

N. F.—The value of old engravings is out of our province. You might get the information from the "Art Trade Journal," 13, Buckingham Street, Strand, London, W.C.2, or you might send the map to Messrs. Maggs Bros., 109, Strand, London, W.C.2, asking them to make an offer for it. They are a very old and reliable firm in the old print trade.

J. M.—The "Photo-Miniature" is issued in this country by Houghtons, Ltd., 88-89, High Holborn, London, W.C.1, from whom you can obtain a list of the comparatively small number of issues which are in print. We are afraid if you want copies of any of the older numbers you will have to write to the American publishers, Messrs. Tennant & Ward, 103, Park Avenue, New York, and probably they have only a few of the older numbers in print.

E. R.—(1) It is difficult to assign a value to the Shepherd lens, as it is entirely dependent upon its quality. If genuine and in good condition it is worth from £2 10s. to £3 to a private purchaser. (2) The Dallmeyer lens is by the number a very early one; its current value, according to condition, is from £4 to £6. (3) Messrs. Sands, Hunter & Co., 37, Bedford Street, Strand, London, W.C.2, might have a flange in stock to fit the Shepherd lens. If not, they would adapt one for a few shillings. You need only send the racking jacket for fitting.

M. D.—We are afraid that in the absence of very complete particulars of the method which is used it is not possible to say what is the cause of difficulty in obtaining uniform sepia tone. We suppose that you refer to the hypo-alum process. Certainly variation in exposure of the paper and also in the degree of development has an effect as regards causing variation of tone, but we do not think that these factors would upset matters to a material extent, that is to say, if exposure and development are reasonably right. It is very doubtful if a particular formula for the hypo-alum bath will help matters, but we may refer you to that on page 773 of our issue of December 30 last. Our experience is that during the last year or two, probably as the result of differences in the gelatines which are used, there is greater difficulty in obtaining uniformity of hypo-alum tone. We should think that your best course would be to obtain the help of the makers of the paper.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3238. Vol. LXIX. FRIDAY, MAY 26, 1922. Price Fourpence.

Contents.

SUMMARY.

In the King's Bench Division of the High Court on Monday last, May 22, Mr. Justice Swift delivered his reserved judgment in the action brought by the Westminster Electric Supply Corporation, Ltd., against Wykeham Studios, Ltd., in which the issue was the right of the electric company to supply current at a power rate greater than the power rate at which it was supplied to other consumers. Judgment was for the plaintiffs. (P. 314.)

In a leading article we deal with the judgment in the above case. One part of it, which is a point to the good, is the ruling of the Court that current supplied for studio arc lamps is current supplied for power purposes. As regards the right (which he held the electric company to have) to supply current for power at a higher rate than that granted to other consumers, the learned judge based his decisionson the alleged greater intermittency of the consumption of current in a studio as compared with that of other users of current for power purposes. (P. 306.)

In the paper this week of the series dealing with the business side of professional photography, "Pelham Swinton" describes a system of ascertaining the cost of photographs produced under the conditions prevailing in a portrait business. The system is based on the average proportional costs for a given output of prints, and provides the means of showing the differences as regards profit between different styles and also of disclosing the fluctuations of cost due to the ups and downs of the number of portraits sold by the studio. (P. 307.)

Mr. Robert Dykes draws a lurid picture of the conditions under which photography has to be done in exploration work in tropical West Africa, and particularly emphasises the necessity of the inclusion of a portable dark-room in the outfit. (P. 310.)

The report of the Eastman Kodak Co. for the year ended 1921 shows net profits of £2,903,424, a reduction of nearly £920,000 on those of the previous year. The hundred dollar ordinary shares are to be split, each into ten shares of "no par value." (P. 314.)

The many interesting studies in natural history which may be made at night by means of flashlight was the subject of a recent paper at the Royal Photographic Society by Mr. Oswald J. Wilkinson, whose flashlight photographs recently received the Society's medal. (P. 311.)

A note referring to a vacancy on the editorial staff of the "British Journal" will be found on page 306.

Mr. Pirie MacDonald is to form one of the R.P.S. selecting committee in the pictorial section. (P. 319.)

Mr. W. L. F. Wastell invites suggestions for the form of the Fox Talbot Memorial. (P. 319.)

Hints on the making of the amidol developer and on preparations for a water shortage will be found in "Assistants' Notes." (P. 316.)

EX CATHEDRA.

The Costing of Portraits. The chapter which appears this week in the series by "Pelham Swinton" on the business side of portrait photography deals with a branch of studio accountancy which our correspondence regularly shows us to be greatly neglected. In comparison with scores of requests for advice on the price which should be charged for certain work, we cannot remember one which disclosed the existence of any system in use for ascertaining the cost of photographs and therefore the charge required for a given ratio of profit. The fact that competition may often determine the charge to the public does diminish the value of a trustworthy costing system. Nevertheless, it is an argument for the more general adoption of a method which should benefit photographers generally by disclosing the unprofitable nature of work the charge for which is unduly "cut." To many, perhaps, the system as set forth by our contributor may have a forbiddingly intricate appearance, and suggest an amount of labour out of proportion to its benefits. Many, at a first glance, will be inclined to put it aside and continue on the time-honoured lines of leaving things to chance. Therefore, we may underline the recommendation which our contributor makes by pointing out that the system consists of two parts: (1) the establishment of average proportional costs as ascertained for a known output, and (2) the application of these costs to a particular job. Part No. 1 having been worked out for a sufficiently long period remains valid so long as the cost items and the output remain approximately the same. Hence the system reveals anomalies in the differences between cost and price of various styles of portrait. But, more than that, it allows of the considerable fluctuation of cost consequent upon variations in output to be quickly ascertained, forming a danger signal of the direction in which profits are tending.

* * *

The Kodak Report. The difficult economic conditions which prevailed in almost every country of the world during 1921 are reflected in the report of the Eastman Kodak Company, issued last week. The profits earned by the parent or subsidiary companies show a reduction of about £900,000, as compared with those of the previous year. Nevertheless, they reach the respectable total of £2,903,425, and must be considered in reference to the fact that 1920 was the most prosperous year in the history of the Company. The falling off is no doubt due to the lesser prosperity of the cinema industry, since the making of cinematograph negative and positive film is the major part of the Company's business, and one which, it is supposed, exceeds all the others put together. The report discloses a very strong financial position in the high ratio of cash and other assets to the issued capital and current liabilities. As has been the case in the balance sheets for years past, goodwill and

patent and trade mark rights stand at nil among the assets. It is announced that each $100 ordinary share is to be split into 10 "of no par value," a unit of capital which, we confess, is unfamiliar to us, and of which the circular letter of Kodak, Ltd., does not provide an explanation. Shareholders, however, have had such good reason to be satisfied with the financial results in the past that they may feel assured of benefit to themselves from the present share-splitting scheme. Of late years the Rochester factories have undergone great expansion, so that the Company is in a better position than ever before to increase its earnings on a scale commensurate with the economic recovery of countries on the continent of Europe and in the western hemisphere.

* * *

Patching the Gelatine Film. As a rule when a negative exhibits defects due to mechanical damage of the film, the custom is to hand it over to the retoucher for spotting out with water colour. If the defect is of appreciable size this is by no means an easy job, and, therefore, it may be of advantage to call attention to the facility with which in some circumstances a negative may be patched with part of the film taken from another. Dependent upon the character of the subject a tear in the gelatine film may be made good by using a bit of film of equal density from another negative. The required patch is cut out with a sharp knife and the negative containing it well soaked in water. By means of a little hydrochloric acid the patch can be detached, washed and applied to the damaged negative with a fine camel hair brush. Very little touching of the negative is then required to make good the damage. It might be thought that the above is a rather difficult operation, but a steady hand and some experience in judging the density of the applied patch will determine its successful use.

* * *

A Post on the "B.J." Since some of those likely to be interested may not be in the habit of looking at the announcements of vacant situations, we may be excused for drawing attention to the advertisement on another page by the publishers of the "British Journal" for an assistant editor. While this advertisement appears also in several of the daily newspapers, we think we may expect to receive applications from those familiar with the "B.J." as regular readers of it. Naturally, a knowledge of photography and the ability to write good plain English are two essential qualifications, in respect to which applicants should submit evidence. It is also asked that applicants should give particulars of employment during, say, the past seven or eight years, including war period, and that letters should not be addressed to any individual members of the staff, but to the publishers, Messrs. Henry Greenwood & Co., Ltd.

* * *

A Scientific Instruments' Journal. From the Institute of Physics comes the proposition to establish a monthly journal dealing with methods of scientific measurement and with the theory, construction and use of measuring instruments. A preliminary number has, in fact, been issued, showing the proposed form of the journal and, as well as can be done in a single issue, the field which it will cover. In an introductory note Professor J. J. Thomson emphasises the usefulness of a journal of this kind, of which there has hitherto been no representative in the English language. It would seem that the projected publication will, in a measure, follow the lines of the "Zeitschrift für Instrumentenkunde," a journal which in the past has published many notable contributions to technical optics. At a price of 2s. 6d. per issue it is estimated that with a circulation of about 1,000 there will be a deficit of some £2,000 per annum, whilst a circulation of about 3,000 will render the journal self-supporting. The promoters are, therefore, anxious to ascertain as accurately as they can the probable circulation, and those who will become subscribers are asked to notify their intention to the Institute of Physics, 10, Essex Street, Strand, London, W.C.2, from which address they can no doubt still obtain copies of the preliminary number which has been issued.

CHARGES FOR STUDIO ELECTRIC CURRENT.

JUDGMENT has now been given in the action brought by the Westminster Electric Supply Corporation, Ltd., against Wykeham Studios, Ltd. On Tuesday last, May 22, Mr. Justice Swift decided in favour of the electric company, and thus disappointed those who hoped that the case might establish the principle that consumers, such as photographers, are definitely entitled, under the Electric Lighting Act of 1882, to the supply of current at a "power" rate at least as favourable as that allowed to other consumers. Nevertheless, although this hope has not been realised, the judgment, so it seems to us, is not altogether without benefit to photographers in efforts they make to obtain terms for the supply of current at power rate as advantageous as those granted to other consumers. We may therefore endeavour to show the issue which has been raised and decided in the case when divested as far as possible of its legal technicalities.

The circumstances of the dispute have already been described in our issue of May 19 last, pages 297-298, and are recapitulated in the judgment reported on another page. Broadly, the Wykeham Studios, Ltd., after having been supplied with current for their arc lamp through a separate meter at the ruling power rate, disputed the right of the Company to continue the supply only at first at the full lighting rate and afterwards at a rate less than this latter, but greater than the power rate. They contended that they were entitled to a supply of current at the same power rate advertised by the Company and paid by other consumers. Now, in reference to both these arguments the learned judge did definitely hold that the current used by the defendants was used by them for power purposes. It is something to have obtained a judgment on this point, namely, that current used in studio lamps, as distinguished from that used for ordinary lighting, is current used for power purposes according to the electric lighting acts. Unfortunately, that does not end the matter so far as the dispute is concerned. The question remains whether an electric light supply undertaking has the right to vary its charges for current for power purposes. May it charge one consumer 1½d. per unit, another, 4d. per unit, and a third even as much as the full rate permitted for ordinary lighting? The Company claimed that in fixing the defendants' power rate at 4d., whilst supplying other photographers in the area at the same rate, they were not infringing the sections in the Electric Lighting Act of 1882, which enforce uniformity in the terms of supply and prohibit preference to one consumer in comparison with another. It is in reference to the Court's interpretation of these sections in their application to photographic studios that the judgment is of chief importance.

These sections in the Act are as follows:—

19. Where a supply of electricity is provided in any part of an area for private purposes, then, except in so

far as is otherwise provided by the terms of the license, order or special Act authorising such supply, every company or person within that part of the area shall, on application be entitled to a supply on the same terms on which any other company or person in such part of the area is entitled under similar circumstances to a corresponding supply.

20. The undertakers shall not, in making any agreements for a supply of electricity, show any undue preference to any local authority, company or person, but, save as aforesaid, they may make such charges for the supply of electricity, as may be agreed upon, not exceeding the limits of price imposed by or in pursuance of the license, order or special Act authorising them to supply electricity.

The Act of 1882, like many other statutes, is pleasantly vague in its terms. What are the "similar circumstances" of Sect. 19 and what is "undue preference," mentioned in Sect. 20. The Act does not say; it leaves it for the Courts to define these matters in the course of expensive litigation, and Mr. Justice Swift reviewed the several cases in which these questions of preference and similarity of circumstances had been the subject of legal decisions. It may be said that these decisions are in agreement in regarding as similar such circumstances of consumption as are alike in the variations they cause in the load upon an electric company's generating station. Obviously, it is inconceivable that the consumptions of even two customers can be exactly similar as regards amount of current, duration of its use, and intervals of disuse. Such a coincidence of three variable factors is a practical impossibility; the mathematical laws of chance make it so. For this reason it is a manifest absurdity to expect similarity of circumstances in greater degree than a rough approximation. Yet, when the learned judge proceeded to apply this doctrine to the facts of the present dispute, he appeared, so we think, to contrast conditions of electric consumption in photographic studios with those in the establishments of other users of current for power purposes in a way palpably out of relation with the facts. Other manufacturers, he held, consume current regularly; photographers, intermittently. At the hearing he appeared to be of the view that in a photographic studio current is used in sudden bursts, like flashlight, and it was rather unfortunate that evidence contradicting this view was not given. But apparently, on this impression it was held that because of this intermittency an electric supply company is entitled to charge photographic studios more for current than it charges other users of current for power purposes. If that, as we think, is the essence of the judgment, electric companies are welcome to all the satisfaction they can get out of it. In future cases it will require to be shown that a studio takes current under a greater variation of load than other consumers if it is to be charged more than those consumers. Apparently, an instrument recording the variation of load on a kind of indicator diagram is a device which is necessary for securing non-preferential treatment of photographers in comparison with other users. The particular use to which the current is put has nothing to do with it. Such, it seems to us, is the position into which the question has been brought by the present judgment. That current for studio lighting has been held to be current for power purposes is a point to the good; the question of similarity of circumstances in future cases must rest on the evidence.

In conclusion, a word deserves to be said on the public spirit exhibited by the directors, Messrs. Emus & Prout, of Messrs. Wykeham Studios, Ltd., in making the question a test action. The amount at issue was not large, and their aim was to establish a case for the supply of electric current to photographic studios at as low a rate as for other power purposes. Although judgment has gone against them they have, nevertheless, scored certain points. Their case was no doubt weakened by the Professional Photographers' Association's acceptance of the Company's offer of 1d. per unit, which figured among the arguments of counsel for the plaintiffs.

THE BUSINESS SIDE OF PROFESSIONAL PHOTOGRAPHY.

[Many photographers, we are afraid, go for years in happy, or, it may be unhappy, ignorance of the cost of producing a dozen portraits of a given size. The technicalities of costing form a branch of commercial accountancy which probably in nine studios out of ten is shirked altogether. Nevertheless, it is a part of the business management of a studio which is of prime importance, and particularly so under fluctuating conditions. The practice of a systematic costing system on the part of the photographer may be compared with the taking of an X-ray photograph for the surgeon who is to carry out an operation. Both reveal a condition of things which is not apparent on the surface. We venture to think that the present chapter by "Pelham Swinton" on this subject is the most valuable because the most needed of the series of papers which, as we hear from many quarters, has aroused widespread interest among photographers and some speculations on the identity of their author. Previous articles have been:—"The Economic Position of the Photographer" (April 28), "The Photographer and His Client" (May 5 and 12); "The Photographer's Clerical System" (May 19). The remaining paper will be:—"The Art of Account Collecting."]

IV.—THE PHOTOGRAPHER'S COSTING SYSTEM.

I TAKE it for granted that all photographers, however humble, possess a cash book which they balance every day, and that, at the end of each month, they draw up for their personal information a statement of their turnover and expenses for that period. It is not necessary here to discourse on the various methods of keeping such books, and the mysteries of double-entry, as such things are common to all kinds of business; and if there be any photographer who is ignorant of these simple modern processes, the nearest accountant will set him right in half-an-hour.

I take it for granted also that the average photographer makes a monthly or annual analysis of these totals, dividing up his turnover under different headings, such as Studio Portraits, Commercial Work, Enlargements, Colour Work, Frames, etc., etc.; his material costs under such classifications as Plates, Papers, Mounts, and Chemicals; and his working expenses under Rent, Salaries, Repairs, Postages, Coal and Light, and so on. I presume all this in order to save space, and because if a photographer possess not the elementary information which such analysis affords him, he is walking

in a darkness even greater than that of his darkroom—for there is no light in that darkness.

There is, however, another form of analysis which the photographer should employ, and from which he can deduce, as nearly as is necessary, the cost of those commodities which he daily produces and which he sells to a grateful public at a price. When I speak of the cost of photographs I do not refer merely to the cost of the materials employed. This is but a fraction of the total cost. Nor do I include merely the cost of the materials, plus the direct labour involved—but also such things as rent, rates, insurance, postages, packing materials, clerical labour, cleaning costs, electricity, coal, law and accounting charges, and the redecorating of the reception room last spring.

Costing systems employed in factories and elsewhere are usually of a highly complicated nature, involving the necessity of a time-sheet for each job undertaken, to be filled in and checked as the order progresses. Fortunately for the photographer, such intricacies are unnecessary, the work which he produces being more or less of a standardised nature. Photographs are produced in standard sizes, with standard materials, and, for all practical purposes, it may be taken that the labour involved in the production of one portrait is the same as that of another. Of course, it is admitted that one negative may require more retouching than another, and that two prints may occupy very different quantities of skill and time on the part of the same finisher; but, in estimating costs over a month or a year, these variations may be overlooked, and an average time or cost be accepted.

This applies also to the time spent in operating, the extra time expended over the difficult sitter being balanced by the ease in photographing the good one. And, as far as printing and mounting are concerned, it may be even more readily accepted that it takes little more time to print and mount a large photograph than a small one. Finally, as regards the clerical expenses, it is just as easy to put a large order through the books as a small one—and considerably more enjoyable.

Thus, if a photographer possess figures which show the total working expenses involved in the running of his printing room for a period of twelve months—including the rent of the room, the proportion of taxes applicable to that rent, the wages of his assistants in that room, the cost of replacing dishes, bottles, etc., during the year, the proportion of cleaning expenses, of heating and lighting, and a certain portion of his own salary for supervision—then he has but to divide that total sum by the number of prints which that room has produced during the same period in order to arrive at the figure which it costs him to make one print. If, then, he requires to know what is the cost of making a cabinet print, it is necessary only to add to this the net cost of a piece of cabinet paper.

Similarly, he may work out the cost of mounting the print, finishing the print, and dispatching it. Then, with regard to the other processes, he may discover how much it costs him to photograph a customer—by dividing the cost of the operating department, which consists of the greater part of his own or an operator's salary and the rent, rates and upkeep of the studio and darkroom, by the number of sitters taken during that year. Similarly, he calculates the cost of retouching by dividing the retoucher's salary, etc., by the number of negatives retouched. Finally, by the same methods, he will learn what it costs him to record an order and send it through the books, and what expense is involved in dispatching it; while the cost of receiving a customer, showing her first to the dressing-room, and then to the studio, he will find to be quite a formidable item.

Having acquired all this information, it behoves the photographer to put it to a practical use; and the first thing he will do is to ascertain the cost of the production of a dozen cabinets, commencing with the reception of the sitter, and including the taking of the photograph, the completion of the order, and the postage or delivery thereof. He will then learn, for the first time, whether the price which he charges for all these services is sufficient to yield a comfortable profit, or whether he has been living for years a life of unconscious philanthropy.

To ascertain this rather important fact, he has but to add together the results of his previous deductions, thus:—

	s.	d.	s.	d.
Reception Dept.—Cost per sitter during year			2	6
Operating Dept.— Do. do.	12	0		
Add—6 plates at 4d. ...	2	0		
			14	0
Retouching Dept.—Cost per negative, 1s.; three negatives			3	0
Printing Dept.—Cost per print, 8d.; 12 prints	8	0		
Add—12 pieces paper ...	1	0		
			9	0
Mounting Dept.—Cost per print, 2d.; 12 prints	2	0		
Add—12 mounts	3	0		
			5	0
Finishing Dept.—Cost per print, 6d.; 12 prints			6	0
Clerical Dept.—Cost per order during year ...			2	6
Dispatch Dept.—Cost per parcel during year (including postage and materials)			2	0
Total ...			£2	4	0

Now this gentleman has probably been in the habit of supplying cabinet portraits at £2 2s. per dozen, and of exclaiming continually at the unlucrative returns of photography as a profession. These figures, although fictitious, are in no way exaggerated, as they are considerably below those which have been arrived at in connection with my own firm.

In order to calculate the cost of a re-order, the same process is employed, but omitting, of course, the operating and retouching costs. Similarly, in the case of a "copy," the cost of the copying department is substituted for that of the operating department, and divided by the number of copies done during the year. As the retouching department deals with copy negatives, as well as those taken in the studio, the cost of this department must be divided by the number of studio negatives *plus* the number of copy negatives. To arrive at the number of studio negatives retouched during a year, it is necessary merely to multiply the number of sitters by the number of proofs which it is the custom of the firm to supply to each client. Again it is admitted that this is only a rough rule by which to calculate a cost; but it is averages with which we are dealing, and, if the photographer is content to charge a fixed price for a certain size of portrait, irrespective of the physiognomy of the sitter, or—within limits—of the nature of the copy or enlargement—he cannot cavil at the acceptance of a flat estimate of costs for the retouching of these negatives. Nor has he need to do so. The only alternative is the elaborate time-sheet; and, in my opinion, this would be merely to use a sledge-hammer to crack the nut.

The photographer who had been charging £2 2s. per dozen for portraits which, on the average, were costing him £2 4s., may still have been able to show some profit at the end of each year, the loss on the cabinets having been balanced by a substantial profit on whole-plates, enlargements, etc. But it is not a state of affairs out of which he could hope to immerge into opulence. If his staple line were whole-plates, however, on which he made a good profit, and cabinets were merely a subsidiary consideration in his business, then he would have no cause for anxiety. For the interesting factor of this aspect of photography is, that, as the overhead and labour costs involved in the production of a dozen whole-plates are barely any greater than those of a dozen cartes, the only

saving in the production of smaller sizes is on the materials employed. Thus, as the photographer must charge considerably less for a smaller size of portrait—for the inflexible reason that the public will not have it otherwise—he cannot avoid a financial loss on at least one size. But the important point is—that the photographer cannot afford to bear such a loss *on his staple or most popular line*. In other words, he must see that his best selling size is in no need of subsidisation out of the profits of other sizes, and that this line stands alone as an economic proposition.

While the public insist on paying very much less for carte portraits than for cabinets, although the cost of production is very little less, they are willing to pay considerably more for whole-plate portraits, despite the fact that the cost of making these is very little more. The whole-plates should yield a sufficient profit to justify their own existence, as well as sufficient to balance the loss on the cartes; while the cabinets should neither give nor receive excess profits. This, of course, is in a business where cabinets are the staple line. The suggestion may be made that the smaller sizes should be abolished, since they involve a loss. Such a course would not be profitable in the long run. The photographer cannot afford to refuse custom, for it is always possible that the carte sitter of to-day may be the whole-plate customer of next year. Besides this, it must not be forgotten that even a carte order helps to pay part, if not all, of its proportionate labour and overhead charges, and increases the firm's expenses only to the extent of a few shillings' worth of materials.

The chief object of the photographer's costing system therefore is to ascertain, from year to year, that his principal size of studio portrait, and his most popular size of enlargement, are being sold at a profit, and that the loss on the smaller sizes is made good by the extra profit on the larger. Further, when called upon to do an unusual job for which he has no fixed price, he has but to refer to his costing figures to learn the price which he should charge. It is obvious that if the photographer can arrange his prices in this manner he will extract from his business annually the maximum revenue that is to be obtained therefrom, and which, I presume, is an object near to his heart. He need have no fear of elaborate books and long hours of clerical work, for the employment of this system involves only one book, and an expenditure of time varying only from two to ten minutes daily.

All that is necessary is a cash book sufficiently long to contain entries for each day of the month on one page, and with fourteen money columns across the double page. There is a standard size made in this pattern. The fourteen columns are headed as follows:—Reception Dept., Operating Dept., Copying Dept., Retouching Dept., Printing Dept., Mounting Dept., Finishing Dept., Dispatch Dept., Clerical Dept., Number of Sitters, Number of Prints, Number of Copies, Number of Parcels, Number of Orders. One double page is used for each month, the dates being written down the left-hand side of the first page.

Let it be understood that by "department" is not meant necessarily a suite of rooms, nor even one room. These divisions are purely nominal, and if, as is probable in many cases, the touching, retouching, and even mounting, are performed in the same room, and by the same people—then the expenses of each of these three departments consist of one-third of the rent of the room, the salary or part-salary of the persons employed in each process, and a proportion of cleaning expenses, coal, light, etc., repairs and renewals being allocated to the department for which they were executed. Thus, if Miss Brown is in receipt of £2 10s. per week, and she is employed during the greater part of the day in retouching, but assists Miss Smith in finishing, her salary may very properly be allocated thus: Retouching Dept., £2; Finishing Dept., 10s. Miss Jones, on the other hand, does all the mounting, but she assists both Miss Brown and Miss Smith in her spare time. Her salary, if she receive, say, £1 15s. per week, may be distributed in this manner: Mounting Dept., £1 5s. Retouching Dept., 5s.; Finishing Dept., 5s.

The important point to be observed is that entries must be made in the various columns *daily*. If such things are postponed for a few weeks, they become a burden; and those photographers who are the proud possessors of that mental defect prettily termed an "artistic temperament" must be on their guard. Each morning, therefore, the photographer glances at the cash book of the previous day, and he finds, possibly, expenses such as the following:—

By stamps	£0	10	0
„ coal	2	10	0
„ repair to copying camera ...	1	7	6
„ pencils	0	0	6

He should keep two stamp drawers—one for parcels and the other for letters and receipts. Thus, if the item of 10s. is for parcel postage, this sum is entered in the Dispatch Dept. column. Then comes £2 10s. for coal. How many fires has he? Five. Very well, that is 10s. per fire. Where are these fires? One is in the finishing and retouching room, one in the mounting room, one in the studio, one in the reception room, and one in the dressing room. Five shillings, therefore, goes against the Finishing Dept., and 5s. against the Retouching; 10s. against the Operating Dept., 15s. against the Reception Dept., and 5s. against the Clerical Dept. The Reception Dept., it will be noted, is debited with the dressing-room, plus one half the reception-room costs, as the clerical work is also carried on there. The item of £1 7s. 6d. for repairs goes under the Copying Dept. column, and the 6d. for pencils, of course, under the Clerical Dept.

The photographer then refers to his day book, and notes, under the respective columns in his costing book, the number of prints and the number of copies entered on the previous day, as well as the number of orders completed. His receptionist tells him how many parcels she dispatched on the previous evening, and he enters this figure, as well as the number of sitters whom he photographed. That is all that is required for that day; and at the end of the month he adds up the columns. These totals being added at the end of the year, a few simple division sums will reveal all the information which he desires.

There are one or two details which must be noted. Material expenses, of course, are not entered in this book; the material costs being easily calculable for any size or quantity. On the other hand, materials such as chemicals should be entered under their respective departments, as these items are spread over the production of all negatives and all prints, and are similar in consequence to an overhead cost. The proportion of rent per room is best arrived at by discovering the rent per square foot of floor-space over the whole premises, and allocating it according to the dimensions of the room in which the "department" is placed. Rates and taxes, of course, are apportioned at so much per pound of rental. Cleaning costs, insurances, and lighting can be split up among the departments in equal proportions, unless there exist any kind of apparatus which consumes more than an ordinary amount of current, or articles which require more than a usual insurance premium. The Clerical and Dispatch Depts. must not be confused. Under the first are entered notepaper, pens, pencils, ink, letter stamps, etc., and under the second are classified packing board, parcel paper, string, sealing wax, parcel stamps, and so on.

The whole scheme involves a certain modicum of common sense, and each business and each circumstance must be considered separately. Thus, one photographer may find it necessary to add a Commercial Work Dept., and many will find a Colour Work Dept. an essential. Whatever the photographer may do, however, he must allow an adequate salary for himself. Even although he own all the business, it is obvious that what he calls "profit" cannot be so until he

has deducted a sum which he would reasonably require to pay for a competent operator-manager to fill his place in the event of long illness, or that which his trustees would require to pay in the event of his death. In the event of his becoming too successful this constant reminder of his mortality will serve to keep him humble. His salary, real or imaginary, he should allocate among the departments, the largest portion under the operating department, and the remainder in equal portions among the others as expenses of direction and supervision.

The costing figures for the past year form the basis for the future. If business proves to be much the same as during the previous year, then the photographer knows that his costs will remain similar; but, if business decreases to any extent, and sitters come in much fewer numbers, then let him beware. For the most important fact to a professional photographer in difficult times is this, that the overhead and labour costs are so large a part of the total expenses that during a time of depression the average cost per sitter, per print, per enlargement, and for each of the other processes, soars at so alarming a speed that the business may be well-nigh overwhelmed before its owner is aware of the danger. During such a period, the photographer should strike his costs at short intervals, and the consecutive results will show with an undeniable vividness the precise time and place for drastic economies.

A mere knowledge that his profits are sadly reduced is of little utility at such a time. He is merely in the position of a surgeon who is aware that his patient is suffering from some organic disease, but is ignorant of its nature and whereabouts. If the patient's life is to be saved, the surgeon must know immediately where to insert the knife. In times such as the present the photographer must ever watch over his business, knife in hand. And a costing system is his only sure means of diagnosis.

PELHAM SWINTON.

PHOTOGRAPHY IN TROPICAL WEST AFRICA.

THE joys of dark-room operations at a temperature of 90 deg.-100 deg. F. under expeditionary methods, where everything in the way of facilities is reduced to a minimum, and both quarters and apparatus have to be improvised, would require the lurid pen of an Edgar Allen Poe to describe. A word of warning to cinematograph and photographic operators attached to expeditions fitting out for the tropics—*carry a reliable small portable dark-room* suitable for changing plates and films and to do a few developing tests in—it is an absolute necessity. Even on the darkest of nights in the forests the darkness is broken every few seconds by vivid blue flashes of tropical lightning, and there is no native hut that is light-tight or rainproof; in fact, the interior of a native hut in the "bush" is a ghastly nightmare to be shut in for an hour. Firstly, it has to be stuffed up in about one hundred or more different places to make it light-tight and to help suffocate the occupant. The next thing, in the absence of a table, is to clear the centre of the floor and squat on it. By the time one is ready to start loading, say, about 1,200 ft. of cinematograph film and unloading the same amount of exposed film, then doing the same with a dozen or two plate carriers, the temperature has risen considerably, and the perspiration is actually dripping off one's fingers over the emulsion. The writer adopted native customs in the way of attire, *but* discoverod that he was not the only occupant of the hut; it was also the home of scorpions, a tarantula spider had been killed in it during the afternoon, beetles buzzed around, *real beetles, weighing over half a pound in weight*. One huge specimen of horned beetle buzzed in with a bang, and smashed the lamp-glass to atoms. Another of the same species collided with one of the expedition in the darkness, and gave him a lovely black eye. It is a very pleasant sensation to be loading film and hear the unmistakable rustle amongst the reeds of floor of some creepy crawly thing, then, whack! a lizard falls out of the roof on to your bare shoulders. The writer had not a portable dark-room, and next time he photographs in West Africa that will be one of the first items on the list.

Coming to the question of exposure, owing to the idea prevalent that the sun being vertical and the light glaring, it is easy to over-expose, and therefore necessary to stop down, one under-exposes, and gets soot and whitewash results. The writer has found that the old adage quoted by him before in his "Night Photography" and other photographic publications holds good in the tropics, viz., "expose for the shadows and let the high-lights take care of themselves." There is, in the first place, a distinct yellow haze occasioned by the intense heat and the humidity. In the second place, a lot of the light is green, reflected from the dense masses of tropical vegetation; other factors to be taken into account also are the colour values of the natives and the soil; the native being a dead black, and the soil highly ferruginous and ranging in colour from yellow through the reds to burnt umber.

The best time to photograph is either the early morning or late afternoon, but one can photograph all day long with care and the protection of an umbrella for the camera. The writer's cinematograph camera got so hot at times it was unbearable to the touch.

Development in the tropics is certainly not advisable, and except for a few tests or an odd plate or two, all exposed film and plates should be packed up tightly in specially fitted tins with calcium chloride and mailed back to England for development. It is a good plan to have oilskin envelopes, into which may be packed film "take-ups" in use, *i.e.*, if a roll of cinematograph film is not finished at the end of the day's work, remove it from the camera and roll up tightly in an oilskin bag. Dark-slides and plate carriers should be treated in the same way.

In development the great difficulty lies in temperature. It is almost an impossibility to keep the temperature down. The image flashes up very quickly, and a good negative may be developed fully out, with normal exposure and diluted developer, in one-half to one-third the usual time.

Fixation is the height of vexation, for it is in the fixing bath that the already softened emulsion meets its Waterloo. After two or three minutes in the fixing bath, even though the emulsion may have been hardened, one may safely look for it under the plate or hiding in the corner of the dish, not unlike a sticky ju-jube. Of course, under proper conditions, where ice is obtainable, one may get fair results—but not lasting—as it is impossible to wash thoroughly and completely eliminate the hypo.

Drying is another difficulty. Apart from the heat and the possibility of melting, ants and various insects make "small-chop," or, in other words, dine off the emulsion, and thrive on it.

The wonders of the primeval forests of Africa are, to a scientist and a photographer, stupendous. One can be observing, studying, collecting and photographing from early morn till nightfall, and after night comes on the great silence is broken by the shrill whistle of countless millions of insects, the babel of sound being not unlike the shriek of a locomotive

whistle entering a tunnel. The darkness is intense even on a moonlight night, for some parts of the bush are so dense that even at mid-day one can hardly see. The only light that breaks the inky blackness is intermittent flashes of lightning and the flicker, flicker, of countless fire-flies. Their tiny little blue light is like a miniature electric arc-lamp, flitting from one side to the other in sinuous waves, suddenly going out as the fly comes to rest on a leaf, then flitting on again. Above these weird noises may be heard the loud agonising wail of the little tree-bear. The wee animal is not larger than a cat, yet it makes a loud, plaintive and most dismal call, louder than many of the larger animals of the forest. Moving through the tangle of rope-like creepers hanging hundreds of feet from the branches of the giant mahogany, cottonwood, teak, and other trees towering skywards, one disturbs many queer denizens of the forest, from monkeys to chimpanzees, and clock-birds to parrots, and chameleons to enormous snakes. As the natives chop the road yard by yard one is kept busy the whole time collecting, studying and photographing.

The difficulties of transport are enormous, and one must leave everything to the native carriers, who carry cameras, instruments, kit, tripods, etc., on their heads as head-loads. It is really marvellous how these native carriers are so sure-footed and careful. The writer wanted to film some waterfalls in the Central Territories of the Gold Coast near the Volta River, and to do so it required all his energies to chop and climb over rock ledges hanging thick with creepers, over huge fallen cotton-trees nearly 30 ft. in diameter at the roots, wading up rapids and crossing the ravines on fallen trees that one had to negotiate on all-fours, yet the native carriers did it, head-loads or no head-loads, and the apparatus, a heavy cinematograph camera, tripod, case of reloads, and an ordinary camera, was transported in perfect condition.

The writer would strongly recommend as a most useful auxiliary camera on tropical expeditions, where all the apparatus has to be transported by means of head-loads, a small camera such as the Baby Sibyl, and a supply of a dozen or two dozen loaded sheaths; also the new small Debrie cinematograph camera. These two cameras could be easily carried in a small knapsack, or even in one's tunic pockets. The writer needed a small portable camera very much, as he missed many wonderful shots whilst climbing through forest glades, where it was impossible for him to handle a heavier camera.

ROBERT DYKES, F.R.P.S.

FLASHLIGHT PHOTOGRAPHY OF NATURAL HISTORY SUBJECTS.

(A Paper read before the Royal Photographic Society, and published in the Society's Journal.)

LITTLE is known of the habits of many species during the hours of darkness, though it is assumed that when not attending to domestic duties birds as a whole merely roost and sleep. On the other hand, even when attending to such duties, some species may still sleep by night, whereas others may continue their activities throughout the day and night, and others, again, only attend to their young ones by night. We may, therefore, set ourselves to investigate and illustrate the life of birds by night, of which, practically speaking, little is known. The Great Crested Grebe, for example, we know, take turn and turn about at incubation during the day, and each parent bird turns the eggs once an hour, but precisely what happens during the hours of darkness we are uncertain of, and have no photographic records by flashlight similar to those daylight studies that have been obtained. Owls are known as nocturnal species, and though there are many beautiful photographs available of their domestic habits by day, there are no records of their behaviour by night. The Manx Shearwater is a bird (not now found in Manxland) which nests in holes in the ground, like puffins. It is rarely seen on land, as most of its life is spent out at sea, only returning to relieve its sitting mate by night. I am told that on one island in the Scillies the scene at night is like a resurrection, so that flashlight records should not be a difficult matter. As another example we may consider the nightjar, which rests like a log all day, but becomes active at nightfall and feeds its young at intervals throughout the night. Precisely how, no one knows, but flashlight may yet provide a solution of the problem.

Insect and Other Forms of Life.

The study of insect life is one that causes a thinking man to pause. It is appalling in its sheer immensity, for the field is apparently illimitable. Sufficient it may be for naturalists in this country to confine their attentions to British species, any one of which will provide ample food for reflection and study in their leisure hours for years. Their name is legion, for spiders, included for 'convenience' sake within the category, comprise no less than 500 different species on the British list, beetles, 3,000, as against 300,000 in the whole world, butterflies and moths more than 2,000, and the number of Hymenoptera, or flies, including gnats, mosquitoes and the like, must run into many thousands.

That photography was an epoch-marking discovery most people now recognise, but outside scientific circles comparatively few really understand the extent to which it has operated in unravelling the tangled skeins comprising the life-histories of creatures connected with their health and welfare.

Flashlight photography is, of course, no new thing, neither is its application to the portrayal of natural history subjects, for Richard Kearton it was, I believe, who first published records of birds and insects obtained in this way when he lived at Elstree in Hertfordshire. For my part the idea did not occur to me until some years later when taking up the photography of wild life as a serious occupation, and it was not until the year 1918 that I undertook research work in that direction.

Early Experiments in Flashlight Photography.

The only data I had to work upon in my early experiments was that kindly given to me by a mining engineer who had taken successful photographs at close quarters in subterranean works, and he informed me that it was necessary to use a fairly short focus lens with a wide aperture. On the conclusion of the Armistice in 1918, and when such work was permissible in the spring of 1919, I ventured to experiment in my garden, and having found a butterfly by the aid of a lamp, resting on some vegetation, I made an exposure by the use of a heavy charge of powder. The result was full of promise, which was confirmed by additional records made of similar subjects, and plans were made for further experiments, because I could see no reason why such an open stop as the one I had used (*i.e.* *f* 4) was really necessary, and moreover a greater depth of focus was imperative if more valuable records were to be obtained. Many plates were exposed from that time onwards with gradually decreasing aperture, until

successful results were obtained of insects on life-size scale and with the lens working at *f*/45.

Having thus established to my own satisfaction one of two important facts, further experiments were conducted with increasing confidence, with a view to ascertaining the quantity of powder necessary, and the amount was gradually decreased until I found that 60 grains was adequate, for life-size pictures with the 6-in. lens working at *f*/32, and using a Wellington Anti-Screen plate.

Throughout these early experiments I was somewhat troubled by scattered high lights in the resulting negatives, and other hard contrasts which caused me to consider ways and means for overcoming the objection. I attribute the absence of hard contrasts, referred to by Dr. Rodman in his kindly reference to my work at the recent Exhibition, to the use of a light-filter which I adopted in all my later work, and to slow development. It was, and is still, my invariable practice to use a K 1 screen for ordinary subjects on anti-screen plates, and either a K 2 or K 3 for Ilford Panchromatic Special Rapid, and I must confess to finding my negatives much less contrasty than formerly.

It was from the middle of the summer season to the early days of autumn in the year 1919 that I contracted the habit of staying out at night, under the pretext of flashlight photography. During that year, and also in 1920, it was my custom to search my garden, which was sufficiently extensive to provide a nightly supply of suitable subjects, by the aid of an acetylene head-lamp from a motor-cycle, and many very interesting insects were revealed, including those which hide themselves by day. Spiders, such as the Diadem spider, the largest British species and common in gardens, are very good sitters. An interesting discovery was made on one occasion when I was taking a flashlight photograph of a spider. The web was a particularly striking one, and, being desirous of securing the best result possible on such a favourable night, preparations were made with extra care. The lens, an *f*/5.9 Zeiss, was not more than 12 to 15 ins. from the spider when the flash was fired from a metal tray placed on the camera bellows immediately above and behind the lens. Closing the slide, the light was turned on to see if all was well prior to exposing another plate, but not a sign of spider or web remained. The duration of the flash must have been so brief as to allow of the photograph being taken before the air disturbance had travelled the intervening distance of 12 to 15 ins. My disappointment may be understood, likewise my surprise when the plate was developed, which was done as a matter of curiosity later on.

One's lamp frequently discloses larvæ of moths and butterflies, feeding and resting, also moths themselves, which ordinarily are exceedingly active at such an hour. Every opportunity should be taken of figuring these finds, as some, such as the Golden Plusia, may prove to be a stranger to the locality. In this particular case the insect had not been seen in my locality previously, and was thus recorded as extending its range northwards. The Brown Spot Pinion, a noctuid species, and very common, invariably hides itself away by day, yet flashlight enabled me to figure this specimen on the hole of an elm. It was of such a placid disposition that I was able to take a stereoscopic record by two distinct flashes, and with a single lens mounted on a sliding panel.

A connecting link between my earliest experiments and those later ones which suggested the possibility of figuring slightly moving objects, was formed when my friend, Mr. A. E. Tonge, F.E.S., discovered the Scalloped Hazel larva at rest on the delicate foliage of everlasting pea, one cold and windy night in October, 1920, when it was photographed as a demonstration of flashlight photography on such subjects. The fact that the foliage was continually in a state of disturbance had not affected the result in any way. This result led me to think that it might be possible to ignore slight movement due to wind, and that if such an assumption be true, one would also be able to ignore slight movement on the part of the subject, within reasonable limits. In this way I came to consider the possibility of snapshots by night through a lens working at *f*/32, and of which I hope to say more later.

It will readily be understood, I know, that one can only touch upon the fringe of the field of work upon creatures in the wild, but prior to passing on to other applications of flashlight photography one should indicate other attractive work for one's camera. The night photographer may adopt a ruse frequently practised by bird-men to attract species to the vicinity of the camera, *i.e.*, by setting a lure, in the nature of a mixture of molasses and rum flavoured with essence of pear or aniseed, on tree trunks, fences, and gateposts. By this means many interesting records may be made of moths, earwigs, woodlice, and centipedes, and perchance a fat old toad in wait at the foot of the tree, for intoxicated revellers to fall. Similarly, it should be possible to attract ants, and burying beetles, to carcasses, and to figure them at work in the free state.

Nature Study by Flashlight Indoors.

We may now pass to a consideration of the possibilities for work upon captive subjects under cover, and thus enter upon a field which is practically immeasurable. We can but subdivide it into sections, any one of which the specialist may select for his life's work, be it lepidoptera, coleoptera, hymenoptera, and so on. The serious student, one imagines, will address himself to a systematic specialised study of one of these subjects only, without complicating matters in other directions. He may decide to investigate the life-histories of British dragon-flies, or spiders, or pond life as a whole, and set himself to study mosquitoes and the like in aquaria at home, but in any case he will certainly have ample material for study and photographic representation. It will not be denied, I think, that the maximum utility to be derived from the application of flashlight photography in the realm of natural history is not to be measured by the number of species merely figured, but by the otherwise unobtainable records of incidents connected with, or inseparable from, the life-history of the creature under observation. It is not what we set out to do, but what we achieve, that counts most of all, and the application of flashlight photography may yet help us to learn something of insect life, and perhaps lead us to new discoveries.

Beyond proving beyond dispute the feasibility of making photographic records of insect life by flashlight on life-size scale, and through a 6-in. lens fitted with a screen, and stopped down to *f*/32 or *f*/45, I had not, up to the summer of last year, carried my investigation very much farther, but in the early summer I continued my experiments indoors upon captive subjects, and having brought a number of larvæ of the Painted Lady butterfly to my home in Cheshire from the Isle of Man, I conceived the idea of making a regular series of photographic records illustrating pupation. In order to do this I arranged a number of thistle-heads in separate bottles of water, and allowed one larva only to each plant, in order that when the moment for pupation arrived my work would not be hampered by the presence of other active larvæ of an inquiring disposition. Happily, one of these insects decided to make preparation for the change before its fellows; and I made a figure of it whilst engaged upon its final feed, as it had become very fat and listless, and inclined to wander from its food plant. I then placed it on a new piece of thistle, and the next day it was found suspended. Twenty-four hours later another negative was made showing the pupa being formed inside the skin, and the head of the larva assuming a hooked shape. It was my intention to take figures every twenty-four hours until the change was effected, and fortunately, when preparing to expose another plate the next day, the larva suddenly became active, and commenced to twist itself about.

so much so that I hesitated to fire the flash. I then noticed that the skin had split behind the head, and that the pupa was emerging so rapidly that little time was lost in making the exposure. As quickly as possible another charge was placed in position and fired, but the skin had been cast in the few minutes that had elapsed, and the elongated pupa hung revealed. It was of a pale grey-green tint, and very shiny in appearance, but it slowly contracted and hardened, changing colour to a dull reddish brown with greyish stripes until, several days after, it had assumed its final form, resplendent with metallic points of shining gold.

In this way many pupal changes may be figured—practically all the metamorphoses of British butterflies, in fact—and I should imagine there would be much difficulty in making such figures in any other way, on account of the continual restlessness of the subject.

It was my intention to follow this series through to the actual emergence of the perfect insect ten to fourteen days later, and had it not been for a pressing business engagement that brought me to London on the tenth day, I feel I would have been able to show the birth of her ladyship. I have regretted ever since that I was unable to complete this interesting sequence, but I hope to make a fresh start *de novo* this season.

Another subject of vast importance which may be studied in this way indoors is that embracing the life-history of aphides. The economy of these interesting so-called pests may be examined indoors, regardless of disagreeable climatic conditions out of doors, and photographs taken at the precise moment when it is desired a record shall be made. Aphides are very restless creatures, at one moment they are nearly all quiet and subdued, and the next they all seem to turn as if obeying some parental instruction. By means of flashlight a satisfactory record may be made without showing any sign of movement.

My own knowledge of these creatures is but slight, but I understand the well-known Hover fly feeds upon the green aphis found upon rose trees, and pupates *in situ*. Finally, the fly emerges from this pupa and, to the best of my knowledge and belief, occupies its time hovering over flowers in the noonday sun, extracting honey and laying eggs.

Colour Photographs.

I should like to say a word in passing relative to colour photography by flashlight. Experiments have been made by the Paget process, but the high cost of Autochromes being beyond my slender means, and receiving no facilities from the agents, I have been unable to do more than indulge in a single exposure on an old plate. The slides I propose to show now are by the Paget process, and will, I feel sure, be regarded as evidence of the practicability of producing pictures in natural colours in precisely the same way as those just shown in monochrome. A great advantage in figuring specimens in this way is that the process becomes a purely mechanical one; no calculation of exposure is necessary, and figures can be made as quickly as the specimens can be pinned upon the board and the charges of powder weighed and laid in position.

In regard to data relative to these slides, I may say the taking scale was unity with a 6-in. lens, stopped down to *f* 10. Plate, Ilford Special Rapid Panchromatic, Paget Special Flashlight Screen placed between the lens components, and taking screen in the dark-slide. Charge of Johnson's professional flashpowder, 20 grains. As Messrs. Lumière supply a special flashlight screen also, there would seem to be no reason why photographs cannot be produced in Autochrome by flashlight as readily as by the Paget process. In both cases restless subjects can be dealt with, whereas this would be much more difficult by day, in fact almost impossible if the lens was stopped down to *f*/32.

Working Details.

As already indicated, it is now my practice to use a light-filter on all occasions, whether working with anti-screen plates or panchromatic plates, a procedure which, of course, necessitates an increase in exposure over the normal. For most subjects, maybe, a non-panchromatic plate may suffice, and in those cases the Wellington anti-screen, with a K 1 screen, will require a charge of flashpowder equal to about 50 grains, with a 6-in. lens at *f* 23, and scale life-size, or 60 grains at *f* 32. These figures are approximate, and not intended to be absolute. Moreover, the character of the subject must be considered in all its aspects, as a subject such as the pupation series just shown will probably require a larger charge of powder than a spider resting on a white-washed wall, or a white butterfly at rest, and conversely a smaller charge than a dull coloured object resting on the ground will require.

When working on restless subjects, such as feeding larvæ, or larvæ changing to pupæ, a very fast plate would seem to be most desirable, in fact high-speed plus panchromaticism would seem to meet the requirements of the night photographers admirably, on account of the necessity for using the smallest charge of powder compatible with efficiency in result. It would appear to me that the larger the charge, the greater the duration of the flash; but I speak subject to correction, and the smaller the charge the more brief it is. I must, however, confess to not having measured the speeds, nor have I been able to obtain any figures from manufacturers. Another important matter, and not the least, is that the powder employed on work of this character should be exceedingly dry, and finely ground, in order to ensure an instantaneous flash; so very imperative, as a slightly delayed flash would probably affect the result somewhat detrimentally. A procedure productive of good results on restless subjects indoors is to use a high-speed panchromatic plate, refrain from closing the lens aperture more than is necessary for depth of focus, and use a small quantity of fine dry flashpowder, such as Johnson's, redried immediately before use.

The Firing of the Charge.

The method most frequently adopted is to fire the powder by means of a piece of touch-paper set vertically in the charge, but this is open to many very serious objections, notably the uncertainty as to the precise instant of exposure. When using touch-paper one has to light it either by means of a match or taper, or some glowing object such as a red-hot poker, or the lighted end of a cigarette. In the interval between lighting and firing of touch-paper the subject may have assumed a pose quite uninteresting and otherwise unsatisfactory, so that in order to overcome this I must confess to having fired my powder direct from a hot cigarette fixed on a skewer. Latterly, however, I have become convinced of the necessity for firing electrically, and intend to adopt this method in future, arranging the mechanism in such a way as to uncap the lens slightly in advance of the firing and to close immediately afterwards. No matter whether working indoors or out in the open, some such contrivance is quite necessary, but in either event, dry powder is imperative. In the former case such conditions are easily obtainable, but when out in the open it is another matter, especially in winter time. True, the operator is able in most cases to lay the charge a few seconds prior to firing from a dried supply, but frequently this is impracticable, for example, when awaiting the gentle noiseless descent of the nightjar to feed its young, the emergence of a fox or badger from its earth, or the appearance of the shearwater at the entrance to its hole. No warning is given, the eagerly awaited and "demd elusive object" of the photographer's patient vigil appears silent and unexpectedly; he must therefore be prepared. How best then can the climatic vagaries of this country be countered? I can only offer a suggestion in the absence of much experience, namely, the possibility of keeping the powder in some form of closed and gently

heated receptacle, the top of which can be thrown back, like a cycle head lamp, at the time of firing, electrically. As one who has spent many nights alone in the wild, on mountain tops, in forest trees, and on the rock-strewn coast, I can speak from experience of the conditions, and having prepared and fired flash-light there, I can anticipate difficulties, and warn would-be experimenters of the deliquescence of flashpowder.

General Observations.

One cannot do more than indicate very briefly a few of the many directions in which flashlight photography can be applied in the study of natural history subjects in the short time available on such an occasion as this.

Reference should, however, be made to the practicability of photographing insects and minute forms of life on a scale greater than life-size by instantaneous exposures. This has already been proved. Experiments in colour photography also lead one to feel sanguine of ultimate success in taking photographs of moving insects in their natural colours, and on a scale several diameters above life-size.

The field naturalist is nothing if not optimistic and, like the fly-catcher, ever hopeful that something good will turn up. For my part I feel that we are but at the beginning of things, and that the application of photography by artificial light to the study of natural history will in course of time show startling developments. We hear of moving pictures being taken by night by the aid of "potted sunlight," and maybe in the not far distant future, perchance more immediate than we anticipate, the nature photographer may be able to show moving pictures of minute forms of insect and other life in all its forms and phases and in natural colours. Flashlight is but a light of exceptional brilliance and actinic power, and some means may yet be found for a prolonged concentration of light of equal intensity to that of magnesium. A modification of the existing type of cinematograph camera should then enable the natural history student to illustrate the whole life-history of many creatures which at the present time are unrecorded.

Such a hope should be our ultimate aim, but we may yet have to traverse a road beset with difficulties, and strewn with disappointments, before we see the realisation of our desires in this respect. At the same time, there is every reason to be sanguine and to feel that we are on the threshold of further developments of an interesting character.

OSWALD J. WILKINSON.

EASTMAN KODAK COMPANY.

THE report of the directors of the Eastman Kodak Co., of New Jersey, which includes the various subsidiary Kodak companies, for the year ended December 31, 1921, discloses a surplus of $5,782,704 (£1,192,310) after charging liberal amounts for depreciation, making allowance for shrinkage in value of inventories, and paying 6 per cent. on the preferred stock and 40 per cent. on the common stock. The net profits for the period are returned at $14,105,861 (£2,908,424), a reduction of nearly £920,000, as compared with the previous year. The latter, it may perhaps be remembered, was the most successful in the history of the company. The report, however, discloses a strong financial position. A total undivided surplus of £11,983,926 goes with an issued capital of £5,394,990.

Two new names appear in the list of directors, those of George W. Todd and George H. Clark.

The following table shows the net profits since the year 1904 :—

Year.	£	Year	£
1904	688,484	1913	2,920,090
1905	827,610	1914	2,332,579
1906	1,116,639	1915	3,245,600
1907	1,446,479	1916	3,564,784
1908	1,540,725	1917	2,998,467
1909	1,619,087	1918	2,897,313
1910	1,850,552	1919	3,778,595
1911	2,401,910	1920	3,828,084
1912	2,886,401	1921	2,908,424

At a meeting of the shareholders of the Eastman Kodak Company held in Jersey City, U.S.A., on April 4, 1922, a proposal to exchange each of the present common shares of $100 for ten (10) shares of no nominal or par value was carried.

New certificates representing shares of no nominal or par value are being prepared. Ten of these shares will be issued to the shareholders in place of each $100 common share now held.

Registered shareholders have been notified that they should at once send their common stock certificates by registered post to the Lincoln-Alliance Bank, Rochester, New York, so that the exchange of certificates may be effected.

Shareholders who have lent their common stock to the British Government will, it is presumed, receive their new certificates from the Treasury on compliance with the regulations recently issued in respect of the return by the Government of the borrowed shares.

Dividends on the common shares will no longer be declared on a percentage basis, but will be at so much per share. Thus the dividend just declared as payable on July 1, 1922, is at the rate of $1.25 (one dollar twenty-five cents) per new share of common stock of no par value.

ELECTRIC CURRENT AT POWER RATE.

THE important case dealing with the use of electric power by photographers was decided by Mr. Justice Rigley Swift in the King's Bench Division on Monday last, May 22, in the claim brought by the Westminster Electric Supply Corporation, Ltd., against the Wykeham Studios, Ltd., of Victoria Street, Westminster.

Plaintiffs sought to recover £82, representing a sum alleged to be due for electricity supplied to the defendants.

Mr. Justice Rigley Swift, in giving judgment for the plaintiffs, said:—In this case the plaintiffs claim the sum of £82 18s. 5d., being the cost they allege to be payable by the defendants for electricity supplied to them at 165, Victoria Street, together with meter rental. On an application for judgment under Order XIV. the defendant company admitted that they were liable to the plaintiffs for the sum of £48 5s. 10d. Liberty was given to the latter to sign judgment of the Court and liberty was given to defendants to defend as to the balance of the claim, £34 12s. 7d.

It was admitted in the course of the action before me that the amount claimed was arithmetically accurate if the plaintiffs were entitled in law to charge the rate they had done, but the defendants contended that in law the plaintiffs were not entitled to charge them at the rate of 7d. or 4d. per unit in the midsummer, Michaelmas, and Christmas quarters for certain electricity supplied, and it was contended by them that they should be charged at the rate of 2d. per unit.

The plaintiffs are a company registered under the Companies Act, 1862-1866, carrying on business under the provision of the Westminster Electric Lighting Order, 1889 (confirmed by the Electric Lighting Orders confirming No. 2 Act, 1889), and they supplied electricity in the area mentioned in the first schedule of the Order and in the area the defendants carry on business as photographers. The plaintiff company has for many years past been in the habit of supplying electricity at two different rates of charge, one rate of charge being applicable to electricity used for lighting purposes and another and a lesser rate being applicable to electricity used solely for purposes other than lighting, and supplied through a separate meter and known as power rate.

The defendants for some years had been in the habit of using electricity for the purpose of a photographic arc lamp used by them for the purpose of providing an exceptional light for the taking of photographs, and it was admitted that the electricity, the price of which this action is now considering, had been used by the defendants for purposes other than general illuminating purposes. In the account which was the subject matter of this action the plaintiffs sought to charge the defendants at a higher rate than the maximum rate stated by them to be payable for electricity used for power purposes, and the defendants object that this current having been taken and used by them for power purposes, that is to say, for purposes other than lighting and through a separate meter, they were not liable to be charged more than the maximum rate for power purposes.

I find as a fact on the admissions made before me that the electric current used by the defendants for the price of which plaintiffs claim in this action was used by the defendants for power purposes and not for lighting, and that it should be charged for at power rate and not at the lighting rate. This, however, does not dispose of the action, for the plaintiffs contend that even if they were under

circumstances compelled to treat the defendants as taking electricity for power purposes only they might still charge them at the rates which they had done in the action, that is to say, 7d. per unit for the quarters ending midsummer and Michaelmas and 4d. for the quarter ending at Christmas, 1921. The right of the plaintiffs to so charge is dependent upon the construction of sections 18 and 20 of the Electric Lighting Act, 1882. By section 19 it is provided that where a supply of electricity is provided in any part of an area for private purposes, then, except in so far as is otherwise provided by the terms of the licence, Order or special Act authorising such supply, every company or person within that part of the area shall, on application, be entitled to a supply on the same terms on which every other company or person in such part of the area is entitled under similar circumstances to a corresponding supply. Section 20 provides that :—" No undertaking shall, in making any agreements for a supply of electricity, show any undue preference to any local authority, company or person, but, save as aforesaid, they may make such charges for the supply of electricity as may be agreed upon, not exceeding the limits of price imposed by or in pursuance of the licence, Order or special Act authorising them to supply electricity.' The meaning of these two sections has been discussed in four cases to which my attention has been drawn. In the Metropolitan Electric Supply Co., Ltd., v. Ginder, 1901, 2 ch. 799 Buckley, J., held that in making agreements the undertaker would have regard to special circumstances, *e.g.*, the amount of energy consumed, the expense of supplying it and getting payment, the uniformity of demand, and the fact that some consumers required energy by day and some by night, and that unless all the circumstances were similar, agreement might be made for different terms and at different rates. In the Attorney-General for Victoria and the Mayor, Aldermen, Councillors and Citizens of Melbourne, 1907, A.C. 469, where under the Victorian Electric Light and Power Act, 1896 (of which sections 38 and 39 were in practically the same terms, as sections 19 and 20 of the Act, 1882), the respondents supplied electricity under two different systems and charges—one at a fixed rate and the other at a rate varying in the unit consumed and the consumer could adopt either system at his choice, and within each system no preference was given to one customer or another, it was held that the suppliers were authorised so to charge and were not restricted to one uniform rate for all electricity supplied by them, and it was held by the Privy Council that the preference prohibited is a preference between customers dealing under similar circumstances and not between customers dealing with two different systems of supply, either of which they are free to select and therefore dealing under entirely different circumstances. In the case of the Attorney-General v. Long Eaton Urban Council, 1914, 2 ch., page 251, Mr Justice Sargant said at page 263 :—I think a fairly clear distinction may be drawn for the present purpose between those reasons for making a lower or preferential charge which under legislation of this kind are legitimate and those which are illegitimate. It would seem that A must not be charged less than B merely to overcome a greater reluctance on the part of A to become a customer in respect of another supply, although either of these reasons might be a good commercial reason for charging less to A were the public undertaker merely carrying on any ordinary commercial business. On the other hand, any circumstances which render it less costly or otherwise more profitable to supply A than B constitute a legitimate reason for making a lower charge to A for the same supply. And if the Court once came to the conclusion that some such circumstances existed, then proof would not be required that the diminution in the charge was precisely equivalent to the diminution in the cost of the supply. In that case the learned judge was dealing with a case in which the undertakers had issued a circular with reference to the price charged for electricity to power consumers, the effect of which was in certain cases to make a lower charge for power purposes to consumer A by whom electricity for the supply of both power and lighting was taken, and a higher charge to consumer B by whom electricity or supply of power or power and partial lighting was taken, and the effect of his judgment is that the differentiation was a breach of the sections, both 19 and 20. By Section 19 of the Acts the supply of electricity to consumer B for power purposes was a supply corresponding with a supply to consumer A for power purposes, and was applied for and given under similar circumstances, and by Section 20 of the Acts the lower charge to A was an undue preference. In the case of the Attorney-General v. Hackney Borough Council (33, "Times" Law Reports, p. 548) Mr. Justice Astbury held that a differentiation fairly arrived at between classes of customers or between customers in any one class *inter se* might be made by the undertakers provided that no differentiation was made between customers taking or entitled to take supplies which corresponded in similar circumstances, and that there was no undue preference given to power users over light users because the circumstances affecting the supply were substantially different in the two cases, and justified in the interest of the undertaking the difference in treatment. On page 549, he said :—These sections say nothing about and do not draw any distinction between light, heat or power users as such. The station turns out only one class of energy, which is measured in Board of Trade units, and the dissimilarity of circumstances and the non-correspondence of supply involved in Section 19 must be looked for not in any difference in the energy consumed or in the manner in which it is led into and distributed by wiring and meterage in the customer's premises, but in the circumstances of the customer himself in so far as they react upon the supply that he takes, and in the time, diversity, and quantity of his consumption. In other words, the purpose to which the consumer puts the energy which he purchases, whether for lighting, power or heating, is *per se* irrelevant : it is in the quantum of, and in the circumstances under which he takes his supply of the one product that the undertaking offers for sale that the answer to the question as to undue preference must be looked for, and it is only for the purpose of classifying customers according to this test that they are for convenience divided into light power and heat classes, such purposes involving, as I have already pointed out—well recognised differences from the point of view of load factor, diversity factor, and the quantity of units purchased. Customers may therefore be and are in practice divided into classes in accordance with these considerations, and they are charged with varying and different rates and classes of rates with the object of encouraging advantageous purchasers and classes of purchasers, as well as of attempting to adjust fairly the respective charges obtained from the station by all. This had led to what is termed different systems of supply being adopted as a fact, for instance, for lighting, heat, power, etc., the customer in each case taking the only thing that the undertakers have to sell, but in circumstances which affect differently the load factor of the station in both diversity and quantity. If the different systems of supply are fairly arrived at, and are at the choice of the customer, the preference prohibited by section 20 is between customers dealing in similar circumstances and not between customers dealing under different systems for supplying (see Attorney-General for Victoria v. Melbourne,, Corporation 23, The Times L.R., p. 753; (1907) A.C., 469) to the extent that the customers under one system benefit the undertaking in the way I have described to a greater degree than customers under agreement, they are given a benefit in the scale of charges. This is expressed by Mr Justice Sargent in the case of the Attorney-General v. Long Eaton Urban Council (30, "The Times," L.R., 537 (1914), 2 Ch., 251), in these words :—" Any circumstances which render it less costly, or otherwise more profitable to supply A. than B. constitute a legitimate reason for making a lower charge to A. for the same supply. Now is the right to differentiate the scale of charges confined to different classes of customers or to different systems. There is not a attitude to the company to make bargains with its individual customers when circumstances differ or the supply does not correspond for different terms." Then what does corresponding supply mean. Does it mean that you are necessarily to treat the small customer upon equally advantageous terms as the large customers. Due cost to the company may be very different. Greater uniformity of demand, easier and less expensive collection of the amount to be paid are circumstances to which regard must be had. (See Mr Justice Sankey in Metropolitan Electric Supply Co v Ginder, 17 "The Times," L.R., 435 (1901), 2 Ch. at p. 811.) Therefore, any differentiation fairly arrived at between classes of customers or between customers in any one class *inter se* may be made by the undertakers provided differentiation is not made between customers taking or entitled to supplies which correspond in similar circumstances which is the only thing that is prohibited by section 19. I think the result of these decisions is that where current is supplied on two different systems, the choice of which is left to the consumers, there is no infringement of section 19 and 20, and that as between customers of each system, the undertakers are entitled to differentiate as to price, provided that the special circumstances of such customer are had regard to. But it was con-

tended by Mr. Blanco White that in this case the defendants using the current for power purposes had been charged more than the rate which was fixed and advertised by the plaintiffs as being the rate for current supplied for power. I do not see why this should not be done, if regard is had to the special circumstances of those who are charged at the higher rate, and if a proper differentiation can be made between them and others, who are being supplied with current for power purposes in the same area. Provided that the undertakers do not charge more than the amount which is fixed by the Act, or which for the time being is agreed upon between them and the consumer, I cannot see why they should not be allowed to charge a consumer more if the circumstances under which he is taking power are not similar to those of other persons who are taking it. Now, in this particular case, the photographers, speaking generally, are not taking current for power purposes under similar circumstances to other manufacturers. Their lamp is not burning regularly and for fixed hours during the day or night, but is intermittently used as occasion necessitates for the taking of particular photographs, and I think that the undertakers are entitled to say that, although their ordinary charge to persons using current for power purposes is 2d. per unit, they would charge a higher rate to persons who take current for use in a photographic arc lamp. I, at any rate, see nothing in the sections to which I have referred, as they have been construed by the Courts in the cases I have mentioned, which is inconsistent with this view. It is clear that here the plaintiffs were under no agreement to charge the defendants other than the rate which they did, and the defendants had ample notice of the rates which they would be charged if they took a current. All photographers in the area using this supply have been treated in the same way, and I see no reason for holding, that the defendants taking this current with notice that they would be charged for it at the rate which they had been, should be relieved from payment of those rates. Under the circumstances there will be judgment for the plaintiffs for the amount claimed, with costs.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Dissolving Amidol.

To open a bottle of amidol, weigh out so many grains, and dissolve it in any room where plates, papers, negatives or prints, are kept or handled, means risking the appearance of a beautiful crop of maroon-coloured spots at an early date. In fact, the keeping of an opened amidol bottle or a pair of scales in such a room may cause a regular occurrence of this trouble. After suffering at various periods, I hit upon the following dodge to avoid it. The water is heated in a large enamel baler, and the sulphite and preservative dissolved completely before touching any amidol. Then a full oz. bottle is submerged in the sulphite solution, and with the clean, small blade of a penknife, the cork is removed under water. By moving the bottle about in the solution, all the amidol will be taken up without any possibility of the salt getting into the air, The formula which lends itself to this treatment is as follows :—

Water (hot) about ...	...	40 oz.
Glycollic acid ...	...	10 grs.
Soda sulphite ...	...	10 oz.
Amidol	...	1 oz. (new bottle each time)

Pour into a Winchester bottle, fill up with water, and use 1 part to 1 of water. This formula will keep. Bromide is optional, but may have to be calculated according to the papers used.

The ounce bottles may be objected to by large buyers or consumers, who are used to the lb. size, but the advantage is so great that this disadvantage is outweighed. Of course the best way of all, to make up any solution, is to do it in a special room, into which no plates, prints, or other photographic tackle ever goes, but this is not convenient everywhere. Another detail which may need mention, is the advisability of removing coloured labels, cork wax, etc., before submerging a bottle. Using Johnson's amidol, I have not found it necessary to remove anything, submerging the bottles just as they are bought, but, of course, the dodge may appear abortive if dirty benches, or opened bottles are near at hand, as traces of amidol on them may still cause trouble.—THERMIT.

Prepared for a Water Shortage.

SOME little time ago I opened the workshop on a holiday in order to get an urgent batch of work through. Just when the major portion was ready for washing, off went the water—and stayed off for the rest of the afternoon. This was discouraging, but as most photographers must know, it was not to be unexpected. The experience caused me to take measures to dodge, to some extent at least, a repetition of this form of annoyance, so I rummaged round next day for something in the way of a large water container. At first I thought of having a cistern installed, but as I did not want to bring in plumbers, etc., at a busy time, I looked for a simpler way out of the difficulty. I was fortunate in finding a small spirit cask in a pharmacist's cellar. This just fitted in a corner by the sink and could easily be filled with the aid of a hose-pipe from the tap. A wooden wine tap projecting over the sink completed the fitment. Two days after installing the cask, it proved its worth by supplying the necessary for making up a few winchesters of solutions, the water-main having temporarily gone on strike again, but since then I have realised its value to a greater extent. Those—and my experience goes to show that they are many—who are troubled with "intermittent" water supplies, know the pettifogging annoyance of placing a measure, dish, or bottle under the tap just one-half second before the water stops to flow and starts to make noises in the pipe for an indefinite period. With a container right at hand, one is independent of these little troubles, and it is worth its room for this only. The only drawback of the above arrangement was that it did not exactly improve the appearance of the room, but this was got over by one of the hands who is blessed with an artistic temperament. He decorated the end of the cask with four big X's in white chalk, and the dark-room consequently looked unusually cheerful.—THERMIT.

Exhibitions.

THE POLYGON CAMERA CLUB.

THE above club, which was formed last year, and consists of past and present students of the Regent Street Polytechnic Day School of Photography, held their first annual exhibition in the School last week, over a hundred photographs, mainly portraits, being on view. Judging from the high level of quality which prevailed, it is not surprising that most of the students make successful portraitists when they start in business on their own account, as most of them do. A noteworthy feature is that in every case the entire production, from posing the sitter to mounting, is the unaided work of the individual worker, thus proving the thorough all-round instruction given by the School.

A very practical innovation was the choosing of members of a well-known firm of photographers as judges; Messrs. Miller and Scott, of Sloane Street, officiated in this capacity. Two medals were awarded by the judges and one by a ballot of the club members.

The awards were:—Portraiture: First (with medal), Miss Daisy Day; second, Mr. A. Riddoch; third, Miss Daisy Day. Landscape: First (with medal), Mr. Howard; second, Mr. Hooper; third, Mr. Hooper. Technical: First, Mr. Hooper; second, Mr. Wilkinson; third, Mr. Obbard. It says a good deal in favour of the general quality of the work when it is noted that a fine portrait by Miss D. Galloway, which has just won the challenge cup of the Northumberland and Durham Federation, did not secure an award here.

In another room a small display of technical work by members of the teaching staff, who all belong to the club, included specimens of oil finishing, Autochromes, photomicrographs, the various stages of photogravure, and portraits by the trichrome process.

FORTHCOMING EXHIBITIONS.

April 22 to May 27.—Royal Photographic Society. Colonial prints arranged by "The Amateur Photographer and Photography." Open daily from 11 to 5 p.m. 35, Russell Square, London, W.C.1.

June 1 to 30.—Royal Photographic Society. Prints by Pirie MacDonald, of New York. Open daily from 11 to 5 p.m., 35, Russell Square, London, W.C.1.

August 26 to September 9.—Toronto Camera Club. Latest date for entries, July 22. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, May 8 to 13 :—

PHOTOGRAPHY.—No. 13,195 Photography. C. Dekker, E. Lewis, and P. S. Kooistra.

BROMIDE PRINTING.—No. 13,306. Means for automatically determining period of exposures in photographic bromide printing apparatus. C. B. Priestner.

PRINTING APPARATUS.—No. 13,510. Photographic contact printing apparatus. W. F. J. Smart and A. L. White.

FOCUSSING.—No. 13,181. Focussing means for photographic cameras. J. S. Stanyon.

APPARATUS.—No. 13,436. Photographic apparatus. C. Wojcik.

PROJECTION APPARATUS.—No. 13,320. Automatically-focussing projection apparatus. Kodak, Ltd.

COLOUR REPRODUCTION.—No. 13,386. Photographic reproduction in colour. A. E. Bowtree and A. R. Trist.

STEREOSCOPIC CINEMATOGRAPHY.—No. 13,005. Means for giving a stereoscopic effect to cinematograph pictures. M. Steinman-Bezencenet.

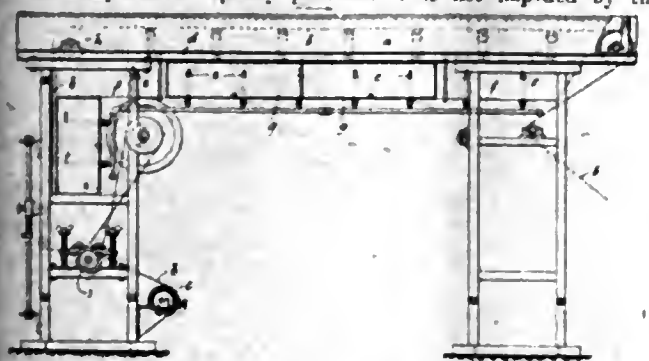
COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; if abroad, in the case of patents granted under the International Convention.

PAPER-SENSITISING MACHINES.—No. 177,073 (April 14, 1921). In the manufacture of certain kinds of photographic papers, e.g., those employed by engineers for the reproduction of drawings, it is usual to unwind the paper from a roll and after applying thereto a ferro-prussiate sensitising medium, to continue the travel of the paper through a heating chamber or zone whereby it is dried to a degree sufficient to enable it to be re-reeled or otherwise dealt with.

The coating of the paper in such instances can be effected with comparative rapidity provided it is not impeded by the



time occupied in drying. This time factor is, however, largely governed by the path available for the paper to travel.

The invention consists in arranging that the heating chamber shall extend vertically from one or other or both ends of the customary horizontal trunk so that for a given overall length of floor space a relatively longer drying path for the paper is obtainable.

In the drawing the horizontal trunk *a* through which the treated paper *b* proceeding from the roll *c* and emulsion-applying device *j* travels is of a form well known, being rectangular in cross section and supported by a pair of longitudinal irons, *d*, beneath which are arranged gas jets *e*, in a heating duct *f*, *g* being doors to enable access to be readily had to such jets. The paper *b* before it reaches the drum *h* in the trunk *a* travels upwardly adjacent to a downwardly directed extension *i* of the heating duct *f*. The heating path for the paper is thus appreciably increased for a given length of apparatus, which increase might be obtained by arranging the extension at the opposite end of trunk *f*, directed either downwardly or upwardly, according to the direction in which the paper is conducted from the machine; or the length of the path may be further augmented by employing extensions at both ends. It has already been suggested, in apparatus for drying photographic paper strips after exposure, toning and fixing, that the strips should be drawn through a horizontal tubular flue, over a guide roller, and then downwards through a vertical part of the flue, thereby gradually approaching nearer and nearer to a source of heat situated at the bottom of the vertical section of the flue.—John William Davies, 30, Rothschild Road, Chiswick, London, W.4.

The following complete specifications are open to public inspection before acceptance :—

TELEPHOTO LENSES.—No. 179,529. Spherically, chromatically and astigmatically corrected telephoto objective. Firm of C. Zeiss.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, MAY 29.

Southampton Camera Club. Print Competition. Subject—Winter and Spring Landscape.

TUESDAY, MAY 30.

R.P.S. "Wild Flowers." Edward J. Bedford.
Bournemouth C.C. Lantern Slide Making. W. L. Carter.
Hackney Phot. Soc. Annual Meeting.
Manchester Amateur P.S. "A Negative, and its Interpretation." Messrs. Bonner, Hadley, Jarrett and H. E. Johnson.

WEDNESDAY, MAY 31.

Bradford Phot. Soc. Outing to Esholt Hall and Woods.
Croydon Camera Club. Members' Print Display.
Dennistoun Amat. P.A. Outing—Kelvingrove Park.
Exeter C.C. Outing to The Red House, Whipton.
Rochdale Amateur P.S. "What is a Good Negative?"

THURSDAY, JUNE 1.

Hammersmith Hampshire House P.S. Annual General Meeting.

SATURDAY, JUNE 3.

Hammersmith Hampshire House P.S. Outing to Marlow.
South Glasgow C.C. Outing to Blanefield.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, May 23, the president, Mr. W. L. F. Wastell, in the chair.

The programme was arranged by the Scientific and Technical Group, and included the following subjects:—

A paper on "Spectroscopic measurements of the hydrogen ion concentration colour changes in recent indicators," by Messrs. T. Thorne Baker and Leslie F. Davidson, was read by Mr. Thorne Baker. It dealt with the changes in the absorption of certain colouring matters (those used as indicators) by acid and alkalies. The authors discussed the usefulness of these indicators in the testing of gelatines.

Dr. Slater Price thought that caution was necessary, in the case of gelatine in accepting colour changes as indications of differences in chemical properties. The colloid character of gelatine could not be neglected.

Mr. K. C. D. Hickman then described a piece of research on the dyeing of silver iodide with methylene blue. He had endeavoured to discover the chemical mechanism which caused silver iodide to mordant a dye and had limited himself to methylene blue B. He

first experimented with silver iodide precipitated from aqueous solution, i.e., without gelatine. Under certain conditions well-washed silver iodide did not fix the methylene blue at all; under other conditions it exhibited two distinctly different degrees of mordanting, one representing a dark-blue dyeing and the other a much lighter blue. In the course of a long series of experiments he obtained circumstantial evidence for the theory that the dyeing of the silver iodide is dependent on the formation of the complex of silver iodide and potassium iodide. Any condition which favoured occlusion of this complex within the silver iodide likewise intensified the dyeing effect. He described also some further experiments on the dyeing of silver iodide images obtained by bleaching the silver image of a plate, as in the Traube process, and referred also to the effect of the tanning action of the developer on the gelatine.

A somewhat lively discussion took place between Mr. Hickman and Dr. Slater Price. Fortunately, when matters seemed to have reached a deadlock, it was suddenly discovered that the two controversialists were in agreement.

A paper on "The function of the flash exposure in three-colour work," by Messrs. E. L. Turner and C. D. Hallam, was read by Mr. Turner. It described the results of the further series of quantitative investigations in half-tone which are being carried out at the L.C.C. School of Photo-Engraving, Bolt Court. In three-colour half-tone, a flash exposure (to a piece of white paper) was necessary for correctness of rendering. The authors had made measurements of the reflection densities of the original and the half-tone reproduction in a number of cases, and had found that the most truthful rendering was obtained by a flash exposure of about 3 per cent. of the time of the exposure employed in making the half-tone negative from the original. Some discussion followed between Mr. Olaf Bloch and Mr. A. J. Bull as to the effect of the characteristic curve of a plate on the gradation obtained in half-tone negatives and the proofs from the resulting plates. Mr. Bloch thought that the shape of the curve had a considerable effect. Mr. Bull did not think that such relation was established.

At a somewhat late hour, Mr. Arthur C. Banfield described and showed the Trist three-colour exposure camera, a most ingenious piece of mechanism for the successive exposure of three (or four) plates for three-colour photography. Its essential feature was that mechanism was provided for setting the lens diaphragm at such apertures that the successive exposures of a panchromatic plate having any ordinary ratio of sensitiveness to the three colour-sensations could be made equal, the same shutter-setting then giving exposures in the accurately correct ratio. On this system the mechanism of the camera provided the means of exposing the three plates in very rapid succession. Mr. Banfield demonstrated the working of the camera by placing an electric lamp behind it and operating the plate-changing and shutter-opening mechanism. The time taken for the exposure of all four plates could not have been greater than five or six seconds.

Votes of thanks to the authors and readers of papers brought the proceedings to a close.

CROYDON CAMERA CLUB.

Mr. Handel Lucas gave a lecture on "The Science of Colour, and Artists' Vision." It was highly interesting in many ways, particularly in illustrating how a distinguished artist, whose paintings have many a time attracted considerable attention at the Royal Academy and elsewhere, need know but little about that branch of the science which relates to the admixture of coloured rays of light, as contrasted with the blending of pigments.

He began with an emphatic declaration of disbelief in the wave theory of light, and regretted time was not available to deal with the matter. Things then began to get a little mixed, and to speak candidly it was often difficult to understand exactly what the intrepid lecturer was driving at. However, he mainly sought to disprove the additive theory of colour vision by demonstrating that its fundamental principles broke down when applied to the subtractive system dealing with pigments instead of coloured light.

As is generally known, yellow is produced by the admixture of certain red and green rays, whether or not colour perception of yellow in Nature is entirely due to this fact. To prove the contrary, Mr. Lucas partially superimposed a disc of red gelatine over a similar disc dyed yellow, and placing the combination in the lantern, showed at the overlap only a dull nondescript colour, far removed from yellow, was transmitted. Other experiments on similar lines followed. A conviction was also expressed that if screen plates were coated with the three pigment primaries, viz., blue, yellow, and red, instead of blue-violet, red, and green as is customary, added brilliancy, and better colour rendering would be obtained.

In the discussion, Mr. Harpur said the lecture had "appealed to him very powerfully indeed." Other optical experts not being Joshuas, mostly preserved a discreet silence, for Mr. Lucas had intimated he would allow no apparently contradictory experiments to influence his mind unless the sun itself formed the illuminant. Unfortunately the orb had retired for the night. It was, however, arranged that three members—Messrs. Purkis, Hibbert, and Budd—should give an evening on the same subject later on which Mr. Lucas promised to attend. Being unblessed with artists' visions, it is anticipated that the cheerful triplets (who are doing well) will not find themselves in complete agreement with his views.

A most hearty vote of thanks was accorded Mr. Lucas.

On the previous Saturday a successful and enjoyable outing was held at the Watermeads, Mitcham, one of the many beauty spots acquired by the National Trust. With the exception of the Easter outing, rambles have met with little success in the past for reasons quite unknown. Mr. Walker, however, has recently been appointed excursion secretary, and if unflagging zeal and hard work can command success it is assured.

Ladies are even to be allowed to join some of the trips, which decision, arrived at in open meeting, filled Mr. Wadham with dire forebodings. With a mournful expression, of amplitude sufficient to cover a dozen funerals and a bit over, he maintained that the innovation meant the insertion of the thin edge of the wedge, and ultimate inclusion of the feminine sex as members of the club. "And that will be the end of things," he added, aghast at the petticoat peril

Commercial & Legal Intelligence.

LEGAL NOTICES.—At an extraordinary general meeting of the members of the Octophototype Syndicate, Limited, held at 224 to 228, Great Portland Street, W., a resolution was passed to the effect that the company be wound up voluntarily, and that F. W. J. Jackson, of Messrs. Jackson, Pixley, Browning, Husey & Co., chartered accountants, 58, Coleman Street, E.C., be appointed liquidator.

A supplemental dividend of 3¼d. in the £ has been made in the case of Frederick Parker (trading as F. Parker & Co.), picture framer and art dealer, 14, Clifton Street, Wolverhampton, Staffs.; and carrying on business at Chapel Ash, Wolverhampton. The dividend is obtainable at the Official Receiver's office, 30, Lichfield Street, Wolverhampton.

Notice is given of the dissolutions, by mutual consent, of the following partnerships: (1) Between Christopher John Grosvenor and Edward Grosvenor, carrying on business as photographers at Cowleigh Road, North Malvern, under the style of C. J. & E. Grosvenor. All debts due to and owing by the late firm will be received and paid by Christopher John Grosvenor. (2) Between Charles Ernest Watts, Walter Robert Hadler and Edward Prime, carrying on business as photographic process engravers at Colchester, Essex, under the style of the Essex Process Engraving Company.

News and Notes.

MR. H. C. PHARAOH, widely known throughout the photographic trade as formerly advertisement manager of the "Amateur Photographer," has been appointed advertisement manager of "The Referee."

A NOVEL WINDOW BILL is being circulated among dealers by Messrs. Amalgamated Photographic Manufacturers, Ltd. It is an exposure chart showing the exposure required for every Apem brand of plate.

War Grave Photographs.—Lieut.-Col. Stanley, on behalf of the Secretary of State for War, stated in last week's Parliamentary Papers that steps are being taken to arrange a contract to take photographs of war graves. Photographs will be sent to the relatives in due course.

Royal Institution.—On Tuesday next (May 30), at 3 o'clock, Sir Percy Sykes delivers the first of two lectures at the Royal Institution on (1) "Travel in Persia," (2) "Foundation of the Persian Empire." The Friday evening discourse on June 9 will be delivered by Mr. Joseph Barcroft on "Physiological Effects at High Altitudes in Peru."

Guilleminot Plates and Papers.—Mr Jules de Gottal, 17, Cecil Mansions, Marius Road, London, S.W.17, sends us a circular of the reduced prices just adopted for the plates and printing papers of MM. Guilleminot, Boesflug & Cie., and intimates that samples of any of the Guilleminot products will be sent to any bonâ fide professional photographer.

Mr. Pirie MacDonald, we are informed by the secretary of the Royal Photographic Society, has accepted the Society's invitation to form one of the selecting and hanging committee in the pictorial section of the forthcoming R.P.S. exhibition. Mr. MacDonald will arrive in England in time to take an active share in this work and in the Congress of the Professional Photographers' Association.

Rapid Photography.—The "Westminster Gazette" refers to a demonstration, given at the studio of the United Film Co., Hampton Hill, last week, when a woman was photographed and the negative developed and printed within two minutes after it had been taken. This process is the invention of Messrs. P. S. Kooistra and C. Dekker, who are both Dutch, and is known as the "Phodeko" developer.

Reflex and Press Cameras.—An excellent list of secondhand reflex and folding focal-plane press cameras has just been issued by Messrs. Sands Hunter & Co., 37 Bedford Street, Strand, London, W.C.2 The cameras are conveniently classified according to size, and full particulars given of every instrument. The list includes a very fine selection of all the leading makes, including a dozen reflexes in the 3½ x 2½ size. A postcard to Messrs. Sands Hunter will bring the catalogue by return of post.

Correspondence.

**** *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

**** *We do not undertake responsibility for the opinions expressed by our correspondents.*

PHOTOGRAPHING AROUND WESTMINSTER ABBEY.

To the Editors.

Gentlemen,—As most of your readers probably know permits to photograph in Westminster Abbey and its Precincts are obtainable from the Dean, but it must not be imagined that the possession of such permit means that the photographer can start work. Something else, it appears, must be done before the photographer can make an exposure—officially, the Clerk of the Works has to be interviewed, and the permit from the Dean should, I think, be more carefully worded.

One official permit reads as follows:—"Westminster Abbey. Permit (name) to photograph the following views or objects in the Precincts, by arrangement with the Clerk of the Works:—(Particulars of subjects). (Signed) Herbert E. Ryle, Dean."

This does not mean, as some seem to imagine, that arrangements have been made by the Dean or his representatives, but that the photographer has to look up the Clerk of Works and make arrangements. If he does not there will be trouble.

The second part of the performance is more difficult than the first. The Dean's permit can easily be obtained by post, but the Clerk of the Works has to be seen.

Last Saturday twenty-two members of a well-known photographic society spent the afternoon in the Precincts under the leadership of an architect, when a hundred or so plates and films were exposed. Their happy wanderings were somewhat marred by the sudden appearance of an extremely officious gentleman, who called for the production of the permit and asked why arrangements had not been made with the Clerk of the Works as directed by the permit. A ten minutes' lecture on what the words on the permit really meant, or were intended to mean, followed, along with some comments on good manners and several other things—a most disturbing interview, and one distinctly out of place in such a beautiful and peaceful setting.

Happily for the photographers the official—who he was is not known—did not appear upon the scene until all plates and films had been exposed, and cameras were being packed up or pocketed. The incident, however, deserves to be recorded, and an explanation of what the wording on the official permit really means may be of assistance to your readers, and save them much annoyance should they ever use a camera in the Dean's Yard, Cloisters, and other parts known as the Precincts.—Yours faithfully,

South Suburban.

THE FOX TALBOT MEMORIAL

To the Editors.

Gentlemen,—The Council of the R.P.S. will shortly have under consideration the question of the particular form to be taken by the Fox Talbot memorial, the subscriptions to which total approximately £200. I shall be grateful if you will allow me, through your columns, to invite all subscribers to send to me, at 35, Russell Sq., W.C.1, any suggestions they may care to make on the matter. All such suggestions will certainly receive the careful consideration of the Council before any definite action is taken.—Yours faithfully,

W. L. F. Wastell.

CLOUD NEGATIVES.

To the Editors.

Gentlemen,—In a very interesting article in your journal of the 19th your contributor opens his remarks by saying that since Mr. Green, of Berwick, discontinued making cloud negatives they are no longer listed by dealers, and he presumes it is not an article of commerce any more.

It may interest you to know that if you refer to page 105 of our abridged list you will see that these are listed both in celluloid and in glass up to 1/1 plate size. They have never been out of our list; not only are they in the list which we distribute ourselves, but they are in the 100,000 dealers' lists which are sold and distributed by dealers themselves, and have been for years, and have never been discontinued.—Yours faithfully,

pp. W. Butcher and Sons, Ltd.,

Isidor Joseph, Director.

Camera House, Farringdon Avenue, E.C.4.
May 23

Liverpool Amateur Photographic Association.—After twenty-one years in Eberle Street, this old association has now removed to 21, Dale Street, where accommodation has been found, one minute's walk from the Exchange Flags, for club and workrooms. The use of a hall has been secured for lantern-lectures and meetings in the Church House, four minutes' walk away, at the corner of Lord Street and South John Street. The lecture hall is a handsomely furnished room, considerably larger than the old club room, whose capacity was often overstrained in past years. The opening house exhibition under the new conditions is to be a show of photogravures by Mr. John H. Anderson. By a happy coincidence the inauguration of the new series of exhibitions thus falls to a Liverpool man. So far as we are aware, Mr. Anderson has not previously exhibited in his native city. Amateur workers in the beautiful photogravure process are all too rare, and Mr. Anderson's work is likely to provide considerable interest among the Liverpool members and perhaps perturbation in the ranks of the Bromoil-transfer workers who claim for their process a beauty equal to that of photogravure.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. S.—As you seem to be clear in your own mind as to the rates which are commonly paid for reproductions in a newspaper of the kind in question (and we think they are about right), the only course is for you to send in your account and to press for payment as greatly overdue. A properly conducted paper would pay, as a rule, at the end of the week or month following publication. Assuming that the copyrights are your own property there is no reasonable doubt that you would be able to recover the amounts by suing the people in the County Court if such is necessary.

H. B.—It is not practicable to coat such large areas of polished surface with a matt preparation, such as could be employed for very small objects. Flashlight at night often will give better results when windows are in such positions that their images are seen reflected, but large quantities of powder are needed for such black objects, especially as the position of the flash must be well to the side. A sheet of newspaper held by an assistant will indicate whether the flash will show as a reflection. No means exist of preventing details on the board itself being reflected, but block-makers all employ skilled aerographists for obscuring such unwanted detail on the print.

J H.—It will be rather a difficult matter to get a really good-looking enlargement from the yellowed postcard. So far as ordinary photographic reproduction is concerned, the best thing that you can do is to make a copy negative on a process plate, and from that an enlargement, preferably on one of the slow gaslight papers, such as Cyko Professional. After one or two trials it would no doubt be possible to get a greatly improved enlarged copy of the postcard, but we really think that the best course in the end would be to send the postcard to a first-rate firm for the making of a platinum or carbon enlargement, leaving the people free to work up the enlargement at their discretion.

F L.—Ordinary M.Q. developer is quite unsuitable for the ferrotype plates. We enclose formula for a combined developing and fixing solution, which gives excellent results with these plates:—

Water, to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo	8 ozs.
Liq. ammonia .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in two or three minutes. They can then be examined in daylight and fixed in plain hypo.

J R.—(1) The F numbers corresponding to the various Goerz numbers are as follows:—

4.6	*f*/6.76
6	*f*/7.7
12	*f*/11
24	*f*/15.5
48	*f*/22
96	*f*/31
192	*f*/45

(2) The Endolithic Manufacturing Co., 60, Aldersgate Street, London, E.C.1, are large producers of cut celluloid labels and name plates. But most likely you would have to get the celluloid cut by a metal plate engraver, such as Mr. H. Cosins, 25, Wellington Street, London, W.C.2.

W. D.—There is little choice of shutters for large lenses, and of those available we think that the Packard Ideal is by far the best. There is one model of this which gives instantaneous exposures as well as time, the speed varying with the quickness with which the bulb is compressed. Exposures of less than half a second may be given on the time setting, and we have found that the sensitiveness to the bulb action may be increased by dropping a few small wire nails into the hollow piston, so that the recovery when the ball is released is quicker. We do not think that the risk of producing pinholes by dust disturbed by a flap shutter is great, as the inside of the camera ought to be kept clean. For many years flap shutters were almost exclusively used in the studio, in days when the average negative had to be much more perfect than it is now.

R. G.—There is no special dictionary of photographic chemicals, at any rate not in English. Valenta's "Photographische Chemie" is an excellent work which deals with the properties, chemical and photographic, of the substances used in photography. But you will find the properties and uses of practically every photographic chemical in Cassell's "Cyclopædia of Photography," now out of print, but on the shelves of the library of the Patent Office, 25, Southampton Buildings, W.C., which is open to the public daily. In the alcove containing chemical works you will also find large chemical treatises in which information on practically every substance can be found. One rather good and recent work is the "Condensed Chemical Dictionary," issued in 1919. Although it is an American book, we expect they have a copy in the Patent Office library.

O. P.—(1) If, as we suppose, the developer is for films, we do not think you should use metol hydroquinone instead of pyro. The developer may be cheaper to make up (we have not worked out whether it is or not), but as regards the quality of the results, we think pyro is much the better. However, a formula is as follows:—

Metol	¾ oz.
Hydroquinone	2¾ ozs.
Sulphite	2 lbs.
Carbonate	1¼ lbs.
Potass bromide	200 grs.
Water	10 gallons.

(2) The yellow filter used for the Paget colour process will have a certain correcting effect on an anti-screen plate, but nothing very substantial. It is quite unsuitable for use on ordinary plates, as it will prolong the exposure considerably without any material advantage. (3) It is a very bad plan to soak negatives after fixing and washing in 5 per cent. solution of sulphuric acid. Any traces of hypo left in the film are decomposed, and are liable to give rise to stain in course of time. Also, the film is rotted to a certain extent unless the acid is very thoroughly washed out. A much better plan would be to wipe the water from the negatives as completely as possible with wash-leather, or by running a roller squeegee over them, and giving a final soak in a couple of baths of distilled water, or in a weak solution of citric acid, which is a very mild acid, without the injurious effects of sulphuric.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3239. Vol. LXIX. FRIDAY, JUNE 2, 1922. Price Fourpence.

Contents.

SUMMARY.

In a contributed article Mr. F. H. A. Hall describes a method of measuring the speed of a focal-plane shutter in which an exposure is made with a shutter of known speed whilst the slit of the focal-plane shutter is travelling across the plate. (P. 323.)

Our contributor "Pelham Swinton" begins the last of the series of articles on the business side of professional photography, dealing with the persuasive or legal methods to be followed in collecting accounts. (P. 324.)

In a leading article we deal with mechanical questions respecting the efficient glazing of the studio. (P. 322.)

In France a local society has been formed with the object, among others, of discovering infringements of photographers' copyrights in portraits by newspapers and others. (P. 321.)

The Edinburgh Society of Professional Photographers proposes to hold a congress, fair and exhibition in Edinburgh next March. (P. 322.)

The Lancashire Society of Master Photographers held a successful conference at Blackpool on May 17 and 18. (P. 329.)

Professional photographers in North Yorkshire and South Durham have formed an association. (P. 330.)

The Photographic Convention will be held at Shrewsbury from July 3 to 8, under the presidency of Mr. C. B. Clifton. (P. 330.)

Mr. D. Charles recommends and describes a form of lens hood consisting of a collapsible frame attachable to the camera front. (P. 326.)

At the Croydon Camera Club last week, Mr. Arthur S. Newman sketched the evolution of the hand camera. (P. 328.)

Flexible sensitive film without gelatine emulsion is the subject of a recent patent. (P. 327.)

Picture postcards may now be sent with a halfpenny stamp and without deletion of the word "postcard" on the front, provided that they bear no message beyond five words of conventional greeting. (P. 321.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

Mr. J. G. Arch, in a contributed article, describes how a repeating back for the taking of a set of three colour-sensation negatives may be made by those of quite moderate experience in the use of tools. (P. 21.)

We describe a laboratory and screen demonstration of a process of colour cinematography which has been worked out by Mr. Aron Hamburger. A single film has images on each side of it, and is simultaneously treated on both sides with four dyes, which are then caused to form a dye image by treatment of the film in a special bleaching bath. (P. 23.)

A contributor describes a fitment for small roll-film cameras permitting of the exposure of Paget colour plates. (P. 24.)

M. J. Carteron, in "La Photo-Pratique," strongly recommends preliminary desensitising of the Autochrome plate with phenosafranine. (P. 23.)

The conditions which chiefly apply to the display of Autochrome and Paget colour transparencies are the subject of a note by Mr. R. M. Fanstone. (P. 22.)

At the R.P.S. recently Mr. Wastell foreshadowed an entirely different process of colour photography. (P. 24.)

EX CATHEDRA.

Postal Improvements. The reduction in the charges for letters and postcards which came into operation on Monday last is, perhaps, not the most substantial part of the steps which are being taken by the Post Office towards the pre-war postal facilities. The resumption of Sunday collections of letters will be particularly appreciated by those carrying on any business which receives orders by post. Newspapers, in particular, have had reason to appreciate the fact that many of the people who send small advertisements draw them up on a Sunday, and that consequently, in the absence of Sunday collections, such advertisements have been late in arriving and, moreover, during the absence of the Sunday collection, have been fewer in number. The publishers of the "B.J." have to deal with some hundreds of advertisements each week, and, therefore, we take this opportunity of pointing out that it is an advantage, as regards certainty of insertion, that such advertisements should come to hand during the Monday of each week. Among the other concessions that have been made, we are glad to see that the Postmaster General has admitted view postcards for transmission at the halfpenny "printed papers" rate without insisting on the deletion of the word "postcard" on the front. When sent at this rate cards must, of course, bear no message beyond five words of conventional greeting; a view card which bears an informative message must be stamped at the full penny rate. The concession removes what has long been an absurdity, and will, no doubt, do much to revive the popularity of the picture postcard.

* * * *

Copyright Infringement in France. An example of a piece of protective organisation in the interests of photographers is described in the current issue of our professional contemporary "Le Photographe." Although photographers obtain copyright in their work in France, their position has never been as strong as in this country, and no doubt rights have been greatly abused by publishers of newspapers. As a step towards the detection and prevention of such infringers a local society has been formed, named the Société des Auteurs Photographes de Normandie, having its headquarters at 75, Rue Thiers, Rouen. In addition to publishing information on copyright law as it applies to photographs, the Société examines the newspapers in its district and compiles a list of the portraits of people which are reproduced without acknowledgment to the photographer, and thus, presumably, in many cases without the photographer's authority. Such lists are to be published from time to time in our contemporary. The first instalment contains the names of about fifty people, and gives such brief description of each portrait as will enable its author to identify it. Those who thus have reason to think that

their work has been reproduced without their permission will apply to the Société for particulars of the name and issue of the newspaper which, it is judged, has published the work without permission. It will be interesting to see whether this local detective work proves effective in bringing the infringers to book.

* * *

Scottish Fair and Congress. With the caution which characterises our friends north of the Border, the Edinburgh Society of Professional Photographers is anxious to ascertain the views of the photographic trade respecting a congress and fair which it is proposed to hold in March next in the new exhibition hall which is being built in Edinburgh. The hall, measuring about 270 ft. square, will be fitted with more than 100 stands, supplied with water, gas and electric power and light. The Edinburgh Society, which has shown itself an exceedingly active and efficient association, proposes to organise exhibitions in the same hall of amateur photography and of professional photographic portraiture. It is felt that the Scottish capital is a centre which will draw large numbers of visitors, and that Scottish photographers will welcome the opportunities of seeing apparatus and of taking part in a congress dealing with the technical and commercial sides of their business. A floor plan of the hall and drawings of the stands are obtainable with other particulars from the secretary of the Society, Mr. Allan Lowson, 116, Hanover Street, Edinburgh.

STUDIO GLAZING.

THERE are many points to be considered when constructing a new studio or re-glazing an old one, and, unfortunately, errors in judgment at such times are costly and troublesome to correct. The selection of a suitable glass is an important matter, especially when the studio is so situated that direct sunlight falls upon the glazed portion for any period during the day, or where it is desired to shut out the view of passers-by or neighbours. In the majority of cases a good heavy "horticultural" glass, such as is used for conservatories, will be as effective as any and less expensive than most. It is usually supplied in two weights, 15 oz. and 21 oz., the latter being preferable, particularly for the roof. Plate glass is sometimes used, but there is not sufficient advantage to be gained to justify the extra cost. Moreover, the original hard surface having been ground away, it is more likely to be attacked by the weather, the surface becoming rough and retentive of dirt. Also, some qualities will darken considerably by long exposure to light, thereby causing an appreciable increase of exposure.

When it is necessary to prevent overlooking, the most obvious thing is to use ordinary ground glass, but it is by no means the best material, as it quickly becomes dirty and smoky. It is not easy to clean, soapsuds and a brush being necessary, which is not convenient in most studios. For the purpose in question and also for diffusing direct sunlight, what is known as "rolled plate" is very suitable. It is a rather thick glass, one side being smooth, while the other, which should be placed inside, is covered with fine ribs or grooves. These grooves should be placed so as to run from the ridge to the eaves, and not transversely. This facilitates cleaning, as the grooves being smooth give up the dirt readily to an ordinary wet leather. Fancy glasses, such as Muranese and similar patterns, should never be chosen, as they are very difficult to keep clean. There is a variety of glass which has a surface similar to hammered metal. This should be avoided, as in direct sunlight it is liable to give a mottled effect if the sitter is placed near to it. Whatever style of glass is chosen the colour should be studied and the whitest sample selected, as this will have a slight effect upon the exposure, enough to be worth considering in dull weather.

The sash bars may be of wood or metal. When first cost is not the primary consideration the latter should always be specified, for not only do they obstruct less light but they are stronger and better adapted for puttyless glazing. Leakage is a chronic trouble in many studios owing to the putty shrinking away from the bars. This is entirely obviated by choosing one of the many systems, now available, of fixing the glass by means of leaden strips which grip the edges of the sheets, any water which may pass under being carried away by small gutters which form an integral part of the sash bars. This plan can also be adapted to wooden sash bars, and in either case, ease of replacement of broken panes is a valuable feature. If, for the sake of cheapness, the old wooden bars are used, leakage may be minimised by mixing about one-third of real Stockholm tar with good ordinary putty. This mixture never becomes quite hard, and consequently does not shell away from the wood. Before glazing, the sash bars should receive two coats of good paint, and the glass should be set in before the second coat is quite dry.

When setting in the glass, care should be taken that the panes are not quite in contact at the overlap, as this will often cause a drip, through the water being drawn up by capillary attraction. Wide overlaps should be avoided, for if dirt is allowed to accumulate in them there is a loss of light besides an unsightly appearance.

The "pitch" or angle of the roof is a matter of some consequence, and the question of steep and flattish roofs has often been discussed. It has been claimed that less light is lost by reflection from a roof with an angle of 25 deg. than from one of 40 deg., but in practice the loss is small and there is a distinct advantage in the steeper pitch, as it is kept cleaner by the rain and will not allow so heavy a load of snow to accumulate before slipping. The single-slant light which has an angle of over 60 deg. gives less trouble in every way than the ordinary ridge roof, and is well worthy of adoption, if it is not necessary to provide for taking large groups.

When erecting a studio, the question of the amount of glass necessary usually arises. Modern practice calls for a much smaller light than was formerly considered necessary, but it is not wise to limit the extent of glass which can be used if need be. In a very large studio the area of glass may be small in relation to the total size of the roof, but in such a studio a great variety of lighting can be obtained by moving the sitter or the camera. In a small narrow studio this is not possible, and if it be desired to obtain the same effects, it is necessary to alter the position of the light. Therefore, in a studio, say 20 feet by 12, there should not be more than four feet of solid roof at each end, and at the end at which the sitter is usually placed the glass may extend to the end wall, so as to allow the light to come from behind the model.

A good deal of glass is generally wasted by having the side light too low. It is rarely necessary for this to come lower than four feet from the floor, thus saving a row of blinds, as well as avoiding risk of breakage and keeping the studio cooler in summer and warmer in winter.

Regarding the question as to the advisability of glazing at least a part of the side of the roof opposite to the principal light, it may be said that this plan is rarely adopted by the most experienced photographers. In

many studios, where glass has been so fixed, it will be found to be painted over or covered outside with felt or iron sheeting. In a few cases where the studio runs from north to south, glass and blinds are provided on both sides, so that in sunny weather one side may be worked in the morning and the other in the afternoon, but even with this orientation a skilful operater will manage to do good work with a one-sided light.

MEASUREMENT OF THE SPEEDS OF FOCAL PLANE SHUTTERS.

THE writer has recently designed a piece of apparatus for the testing of speeds of focal-plane shutters. The object aimed at was to give, by means of a front shutter of *known* speed, a comparatively large number of exposures during the time taken by the slit of the focal-plane shutter in travelling from top to bottom of the plate. This, as Fig 1 shows clearly, will

Fig. 1.

give an image of the slit for each exposure by the front shutter, and a simple calculation based on the number of images, the number of exposures per second front shutter, and the width of slit, will give the effective exposure of the focal-plane shutter.

The reliability of the test depends entirely on the speed of the front shutter being measurable. The most accurate and constant method of making the exposures, it seemed to me,

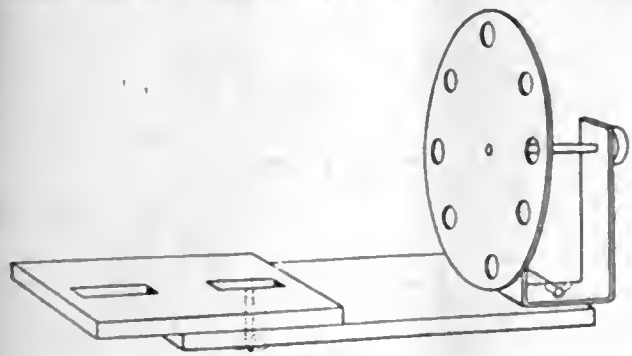


Fig. 2

was to use a falling weight, which, as is well known, completes 16 ft. in one second. This gives for 4 ft. (about the average for a tripod) a speed of 8 ft. per second at the *end* of the fall.

A disc of thin card (Figs. 2 and 3), about 6 in. diam., is mounted on a spindle passing through two bearings and carrying a grooved pulley on the outer end. The disc has 8 equally spaced holes punched in it, $\frac{3}{4}$ in. diam., allowing sufficient margin from the edge to act as a light trap; say, from the outside edge of the hole to the edge of the disc $\frac{3}{4}$ in. A piece of card with a $\frac{1}{2}$ in. hole in the centre is fitted in the front of the lens mount to allow the smallest space consistent with free running between the disc and the lens front.

The bearings for the spindle are made by bending a strip of brass $\frac{1}{2} \times \frac{1}{8}$ in. twice at right angles and drilling holes in the free ends for the spindle to pass through. The base of the bearing bracket is clamped to a wooden support 1 in. square by about 6 in. long. This piece is again clamped to a similar piece which should be long enough to reach under the tripod head so that one screw will serve to attach the camera on top and the apparatus from below by using a longer $\frac{1}{4}$ in. Whitworth screw than the one supplied with tripod. It will be found to add greatly to the convenience of adjustment if the supports are slotted at each joint and small bolts with wing nuts used instead of ordinary screws.

A weight of about 3 lbs. is attached to a length (4 ft.) of strong thread with a loop on the opposite end, which is placed

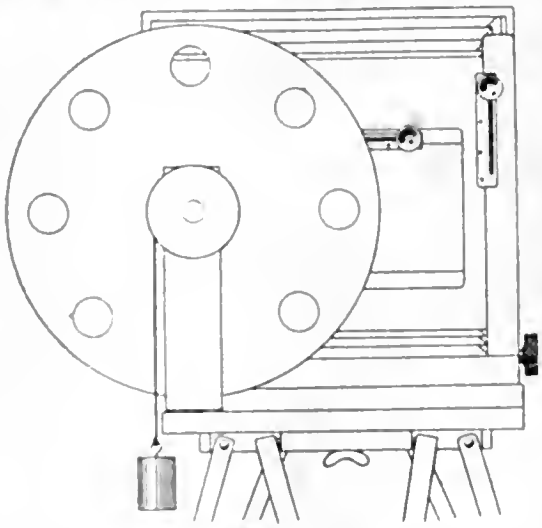

Fig. 3.

over a small pin driven into the bottom of the groove in the pulley. The weight is wound up to the top and held in position by a loop of thread placed over end of spindle. Fig. 2 shows the apparatus detached, and fig. 3 in position of use.

The shutter is now set with a *narrow* slit and wound up, the dark slide put in and the shutter drawn. The camera is pointed to a clear space of bright sky. The loop of thread which holds the weight from falling is cut through and the focal-plane shutter is released just as the weight strikes the ground, at which moment the disc will be revolving at its maximum speed. On development the negative will be found to be crossed by a number of dark bands which are images of slit, the actual number varying with the speed of the focal-plane blind. There is no need to hurry in pressing the release

as the time taken for the weight to attain its maximum speed is quite sufficient to allow of reasonable deliberation. With shutters having a fixed tension and obtaining variable speeds by altering the width of slit only, one negative will give the data required. If the speed is altered by winding up a tension spring a fresh negative must be made at each tension, as the actual speed of the blind is not then constant.

The diameter of the pulley on the fixture described is 1 in.; that is, 3.141 in. circumference.

The speed of the weight (maximum) is 96 in. per second: 96 divided by 3.141 = 31 (approx.), so that the disc makes 31 revolutions per second.

There being 8 holes in the disc, each exposure represents 1/248 second (8 × 31 = 248). The number of dark bands shown on the plate divided by 248 gives the fraction of a second taken by the focal-plane blind to complete its travel, and this divided by the number of slit-widths contained in this height of plate denotes the *effective* speed of focal-plane shutter.

Taking Fig. 1 as an example—

Width of slit was	.10 in.
Height of plate	3 in.
Number of slit widths in 3 in.	30
Number of images of slit	15
Speed of front testing shutter	1/248 sec.

1/248 ÷ 15 = 1/16.5 sec., which is time of travel of blind. This is multiplied by 30 (number of slit widths in plate). 16.5 × 30 = 485 gives the *effective* speed of the focal-plane shutter as 1/485 sec.

Fig. 4 is a print from a negative of an express train, using the same width of slit, taken at about 45 deg., and moving some 40 miles per hour. I have enlarged it as nearly as possible twice *linear*, and though there is a *slight* advance of the upper portions, the funnel and dome, owing to the time taken for the slit to pass over the distance from the rails to the highest part, it would not be noticed unless specially looked for. I merely include this as a sort of corroboration of result of the test, as the shutter speed indicated agrees very closely with that given in the tables in the almanac for such a subject.

There would be no advantage in increasing the speed of the front shutter to any great extent, as a speed would soon be reached when the image of the slit would overlap, or even two exposures of front shutter might take place before the slit had time to travel its own width. The method, for this reason, is only available for narrow slits, from the results of which tests the slower speeds are easily ascertained. With shutters with fixed tensions one test negative will serve, but where the speed is altered, both by variations in tension and width of slit, a separate test negative must be made for each tension.

There is another point in the analysis of the movement of the blind which is clearly shown on the test print, *i.e.*, the

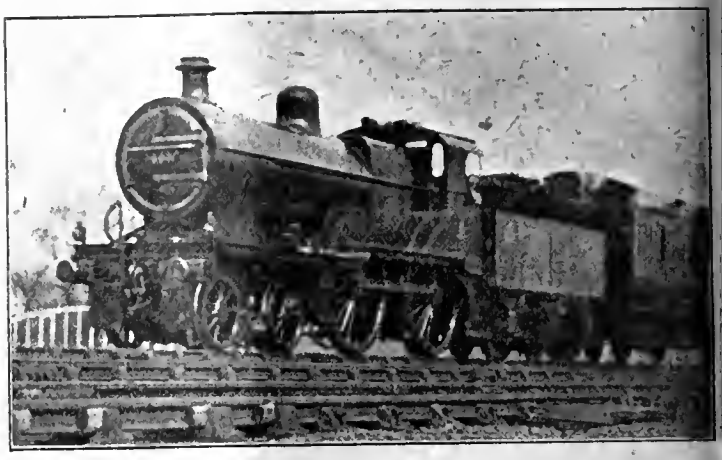

Fig. 4.

acceleration; the dark bands are close together at the top and get wider apart till about the half distance, beyond which position they are nearly equidistant, showing that the blind has then reached its maximum speed. This might suggest some advantage from giving the blind a longer travel than actually needed at the top, so as to overcome inertia before commencing the actual exposure, the extra time being allowed for by releasing shutter a fraction of a second early. I intend to make further tests with the blind running upwards, and also with slit vertical, which should show whether there is any great advantage to be gained by running the blind in the opposite direction to movement of object.

F. H. A. Hall.

THE BUSINESS SIDE OF PROFESSIONAL PHOTOGRAPHY.

[The subject of the last of the chapters on the business side of professional photography, namely, the collection of customers' accounts, provides our contributor, "Pelham Swinton," with special opportunities for exhibition of his mordant wit and shrewd insight into human nature. The whole chapter is unfortunately too long for completion this week, but its appearance in our next issue will end the present series. Previous chapters have been:—"The Economic Position of the Photographer" (April 28); "The Photographer and his Client" (May 5 and 12); "The Photographer's Clerical System" (May 19); and "The Photographer's Costing System" (May 26). We think that those who may have overlooked any of the previous papers will be grateful to us for these references.]

V.—THE ART OF ACCOUNT COLLECTING.

In those far-off dark ages when our rude forefathers knew not the use of money, and conducted their commercial transactions by means of barter, I think it hardly probable that any system of credit was in practice; and such things as bad debts, or the expenses involved in the extraction from one man that which belongs to another, are evidently the growth of politer periods. Credit, in a more or less nebulous form, first made its appearance in the Middle Ages when the noble lord took from the vassal, or from some weaker person, that which he had a fancy for without any intention, either tacit or implied, of payment or restitution. During the eighteenth and early nineteenth centuries, when one of the measures of a gentleman was the volume of his financial obligations, morality had advanced so far that intention of repayment was always implied. Nowadays, the moral and legal necessity to pay for whatever one purchases is almost universally admitted; but we have not yet arrived at a state in which it is universally practised.

The custom of giving and taking credit, one of the direct inheritances of the feudal system, has been found by economists to be not entirely harmful, in that, when used with moderation, it supplies the very necessary oil for the wheels of

commerce. As a lubricant, therefore, it is a blessing; but when it is allowed to develop to such an extent as to transform a business into a polite form of loan institution for the benefit of an improvident public, then such credit is a curse both to the trader and to the community.

The broad principle of the advantages of retail credit is simple. When I require a new suit of clothes, it would be a great inconvenience to me if I were obliged to visit my bank, draw a sum which I calculated would suffice, and then proceed to my tailor, money in hand. To the tailor it would be equally a disadvantage. The trouble involved to myself might cause me to postpone the purchase until another day, and by then I might have decided that the old suit would last another year. Thus there is inconvenience caused to me, and a possible loss to the tailor. Under conditions of credit, however, I walk into the shop when I happen to be in that district, order my suit, and, at a convenient date, send him a cheque for the debt incurred. Further, when I know that I have an account standing against me with the tailor, I am tempted to purchase from him several extra small articles of which I am more or less in need, but which I might hesitate to buy were I obliged to pay cash on each occasion. This, again, is an advantage to the tailor, and for such advantage he is willing to forgo immediate payment for his goods, or, in other words, to lose interest on the amount of my account—for a certain limited period. But if that period be extended by me for twelve or fifteen months, then the tailor will begin to wish that I had purchased a little less and had paid more promptly.

The value of credit to the retailer, therefore, has very definite limits, and, to the public who purchase from him, it is merely a matter of convenience and does not involve any of the complications associated with high finance. There is consequently no reason for the extension of such credit beyond that period which affords the convenience described. One month is an ample period to serve such a purpose, and there is no logical argument which could prove it inadequate. A man may exclaim: "O, but my salary, or my dividends, are not due until six months hence. I cannot possibly settle my accounts till then." This is not an argument. It is merely an admission that he is living in advance of his income—a state of affairs which he should never have permitted. If, however, such is really the case, and the circumstances were unavoidable, then let him borrow the necessary money honestly, at an interest per cent., instead of forcing the retailer to finance him at no interest at all.

Many photographic firms conducted on the credit system have long been in the habit of permitting accounts to remain unpaid for absurd and uneconomic periods. I say this with conviction, because my own firm was one of these. In some cases this state of affairs is due to laxity; but in the majority of businesses it is the result of sheer moral cowardice. The creditor is afraid to press the debtor lest he should lose his custom. Can anything be more pitiable, more disgustingly servile? In a country where so much is talked about freedom and justice, one would hardly imagine such circumstances possible. Yet they exist every day, and in all kinds of businesses, where nineteenth century methods hold sway.

The position is plainly this. The photographer makes a contract with the customer to supply a certain number of portraits of a certain size, in return for which he shall receive a certain agreed sum of money. It is simply an exchange. If the photographer has performed his part of the contract to the satisfaction of the customer, then there exists no reason, either ethical or legal, why the customer should not fulfil his or her agreement to the satisfaction of the photographer—i.e., within a reasonable period.

The truth of the matter is, that the photographer's fears are entirely misplaced. He fears to offend a customer, but he has evidently no fear of the scarcity of floating capital which such conditions create. He has no fear that he will be rendered unfit to compete with his rivals in normal times, and he has no fear of bankruptcy should trade become bad. Rather let him fear these things. It is the man who has floating capital in hand who can outrun his competitors, and it is such a man who, in times of depression, can stand securely until better days. And, as regards the offending of the customer, this is but a children's bogey, which disappears in the light of up-to-date and reasonable methods.

A human being withholds payment of a debt, for at least one of four reasons:—Either through forgetfulness, through dissatisfaction with the goods supplied, through a temporary inability to pay owing to financial embarrassment, or through a determination to pay nothing until compelled to do so. To do justice to human nature, the first cause is the most common, especially in the case of small accounts; and it is for the individual photographer to see to it that the second cause is made as uncommon as possible. The third cause is probably nearly as common as the first; while the fourth is merely an evidence of the spirit of the Middle Ages still among us. This, fortunately, is not so much in evidence as it was ten years ago. The growth of morality is like that of education, very slow; and to certain types of persons it can be introduced only by means of a surgical operation. The minds of persons who have been educated to regard tradesmen, and people who buy and sell, as beings of an inferior creation considerably lower than the angels, and whom, in consequence, it is no dishonour to cheat, have recently been bathed in a flood of democratic light. This influx has had a most salutary effect; but it required nothing less than a European war to create the necessary cranial fissure.

In the event of payment of a debt being withheld on account of dissatisfaction with the goods supplied, no breach of contract is evidenced, as the contract on the part of the creditor has not been fulfilled. The customer, however, has no right to delay to inform the creditor of this, otherwise, he is at fault. As a rule, however, people are quick to point out shortcomings or mistakes, and do not usually delay this beyond the rendering of the first account.

With regard to the other three causes of delayed payment, what is the photographer to do? A repeated rendering of the account at fixed intervals for an indefinite period of months or years, is the usual and time-honoured procedure, and, if payment is not made by a date coincident with the expiry of the photographer's patience, the matter is placed in the hands of a solicitor or debt-collecting agency.

Now, a letter from a solicitor or agency has an extraordinary psychological effect. No matter how carefully or courteously worded, it is always described by the recipient as "insulting." Everyone knows the curious reflex action of the nerves of the leg, when, sitting with knees crossed, the bone below the upper knee is struck sharply. The foot and leg jump forward involuntarily, and cannot be controlled. In the same manner, a debt-collecting letter from a solicitor seems to strike some similar spot in the brain, and the recipient immediately cries out "insulting!" I have known some who felt so outraged as to threaten legal action against the sender—and this, be it observed, after months of weary account-rendering in a humble endeavour to obtain one's own.

It is advisable, therefore, as far as is possible, to keep one's fingers from contact with this tender spot in the human mentality. However inconsistent or ridiculous it may appear to the normally-minded, some persons do feel righteously aggrieved at this request for payment of a debt. And here is the whole point. It is not so much the request at which they are incensed, but on account of the person who makes the request—the fact that the letter is from a solicitor. In describing the communication as "insulting," therefore, they seem to be unable to distinguish between the phraseology of the letter, and the implication of its origin. Thus, if such a letter be sent by the photographer himself, the debtor will not feel insulted at all. In fact, the photographer may write

in very much stronger terms, and still the recipient will feel no insulting effects.

Why, then, should the photographer cause offence to his customers in this manner? To offend customers is to lose them; and the only customers whom he can afford to lose are those of class No. 4 who endeavour on principle to evade all debts. Obviously, these are the only people who are deserving of the solicitor's attentions. The other two classes—1 and 3—are more or less innocent persons—the one type careless and forgetful, and the other financially embarrassed. Each of these, therefore, must be treated separately, and they are distinguished the one from the other by a simple process of filtration, or sifting. Here it should be mentioned that the photographer is wise who sends out his accounts every month. Longer intervals than this mean bad debts, and awkward scarcities of ready cash. A large number of persons never pay an account until it has been rendered from two to four times. If, then, a man renders his accounts quarterly, he must be prepared to wait from six to twelve months for the average customer's payment. If he prefers to do this, I have no quarrel with him; but I prefer to put my floating capital to more productive uses. Further, it is an excellent plan to place an account beside the photographs when the order is despatched. This offends no one. Old customers treat it as an invoice, and it assures that no misunderstanding can arise regarding the price charged. While—most important factor of all—it is surprising how many people will be found to pay within a few days of the receipt of the order.

The reason of this is important. When I purchase almost any other commodity (excepting food), I am still in possession of the article when the account has to be paid. But, when I purchase photographs, the first thing I do is to scatter them broadcast among my friends; and, when the account arrives, perhaps a few months later, the folly is past and well-nigh forgotten. This rude reminder is most unpleasant. The money which I had arranged to set aside for the photographs has been spent a month ago on something else, and, the cause of this account being no longer present to give me a feeling of value received, I naturally look upon it as money thrown away. For these various reasons, therefore, the account is put aside, where it is forgotten, and where it lies unpaid for months. On the other hand, if the account is enclosed with the photographs, it is highly probable that I shall settle it almost immediately, while I am interested in the photographs and while the cash is at hand, for people rarely indulge in a luxury unless they have the money to pay for it. There is, therefore, nothing to be lost and everything to be gained by the photographer encouraging his customers to pay their accounts as quickly as possible. But how? Here I must break off for lack of space and postpone my discussion of the practical side of account collecting to next week's issue.

PELHAM SWINTON.

THE IDEAL LENS-HOOD.

THE ideal lens-hood, like any other ideal photographic apparatus, does not exist. The fact is that comparatively few photographers fully realise the advantages of a lens-hood at all.

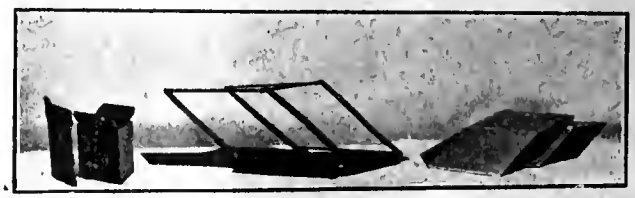
Perhaps it would be as well to state the qualities which the ideal lens-hood should possess, in my opinion:—Firstly, it should cut off brilliant light which is not part of the subject, and which would otherwise strike the lens and flatten the image on the plate. That, it will be said, is the sole purpose, the be-all-and-end-all of a lens-hood. Agreed, but still there is a second. It should cut off all such extraneous light without itself intruding on to the plate, and should therefore be adjustable to various lenses and extensions of a camera. Thirdly, too, it should not take too long to attach and remove, and it should not occupy more than its fair proportion of space or weight in the camera bag.

The larger and the more distant the opening of the lens-hood the more closely it can be adjusted with ease to cut off all image that is not going to form part of the picture. Also, if one can prevent the inside of the hood from presenting a bright surface when viewed from the rear, it is obvious that as regards photographic qualities we shall have attained our ideal. There are, however, matters of convenience that have to be studied. The form of hood which consists of bellows connecting two wooden frames is a fair approximation to the ideal as regards technical efficiency, but if employed of a size that permits of accurate cut-off as well as the use of a rising front, etc., it is often considered rather cumbrous, though this would not be a serious objection were it made in such a way that it permitted of rapid and easy attachment to a variety of lenses, large as well as small, such as the commercial worker has to carry.

The lens-hood which I propose to describe is one which meets these objections, inasmuch as it is not attached to the lens at all,

but to the camera front. Any objections to its bulk are met by the fact that, when collapsed, its dimensions are practically of area only, its thickness being less than a quarter-inch, so that the space it occupies in the camera-bag is negligible. As the cost of the materials for making quite a large one is less than sixpence, it will be appreciated that a great step nearer to the ideal has been accomplished.

These materials consist of thin cardboard and book-binders' cloth, with thin glue as an adhesive. The card is cut into the necessary pieces, all of equal size, which are stuck upon a strip of the cloth with about 3/16 in. space between each for flexibility in folding. Another strip of the cloth is stuck on the other side, and, of course, each strip has an end which overlaps and makes a secure join at the fourth corner. For average lenses the best dimensions are in the proportion of four-by-three; that is to say, the opening would be four inches square and the depth of the hood from front to back would be three inches. By adding side wings of narrow strips it becomes possible not only to have some little control over the size of the opening by tucking these wings more or less back inside the walls of the hood, but it is found that this very simple addition makes an intense black shadow just inside the opening of the hood, which thus forms a far more effective cut-off than a plain opening. The difference in effect is astonishing when first seen, but in practice it will be found quite sufficient in the vast majority of cases to have wings at two sides only. To obtain the greatest range of adjustment it is very desirable to have a double hood, i.e., an outer hood which slides over the one attached to the camera, and to have the wings upon the outer hood. There are several ways



in which the hood can be attached to the camera, the best being simply that in which two small round-head screws are fixed in the camera-front coinciding with holes in wings at the back of the hood (not to be confused with the front wings previously mentioned). A rubber band round the hood catching under the heads of these screws will prevent any chance of slipping off. The outer hood is simply slipped over this one and slid backward or forward according to the lens in use, and for wide-angle work the inner hood is used alone. The illustrations show hoods constructed on these lines, open and partly closed for packing. A hood on similar lines for use where the lens is mounted in a diaphragm shutter is also shown. The frame is made of hard brass, and is supported on the camera front by keyhole slots which fall over the same screw-heads, and the outer hood slides over this in the same way.

The brass strips forming the front of the frame make a non-reflecting diaphragm inside the hood just as the cardboard wings do.

The best size to make a hood is the largest that the camera front will carry conveniently. So long as the proportions are the same the larger hood will cut off exactly the same amount of outside light, but with less risk of vignetting. Anyone who has ever tried shading his lens with his hat or with the baize partition of his camera-case, and has found half his picture cut off, will appreciate the advantages of a hood of this kind which will, moreover take up no more room than the said partition.—D. CHARLES.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications May 15 to 20 :—

VIEW-FINDER.—No. 14,173. View-finder for photographic cameras. E. H. Binney.

CAMERAS.—No. 14,307. Photographic cameras and printing apparatus. H. R. Eason.

PANORAMIC CAMERAS.—No. 14,057. Panoramic cameras. De P. M. Paulson and S. Richards.

TRANSFER PROCESSES.—No. 14,074. Final supports for photographic transfer processes. T. W. Ellis.

TELEGRAPHIC TRANSMISSION OF PICTURES.—No. 13,902. Method of transmitting pictures by telegraphy. B. S. Clay.

COLOUR CINEMATOGRAPHY. No. 13,803. Colour cinematography. H. May.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country, or abroad, in the case of patents granted under the International Convention.

CELLULOSE FILMS.—No. 162,266 (April 19, 1920). An aqueous solution of potassium iodide is prepared in which silver iodide is dissolved until the solution is saturated.

The film is then immersed in the bath. As soon as it is sufficiently impregnated it is withdrawn and squeezed, and then soaked in water. The resulting dilution of the potassium iodide solution sets free a large quantity of silver iodide which is deposited in the interior of the film, and renders the latter sensitive.

The same result can be obtained by using in place of the silver iodide solution above referred to, for example, a warm solution of silver bromide in an aqueous solution of an alkaline bromide.—La Celiophane (Société Anonyme), 16, Rue de Louvre, Paris.

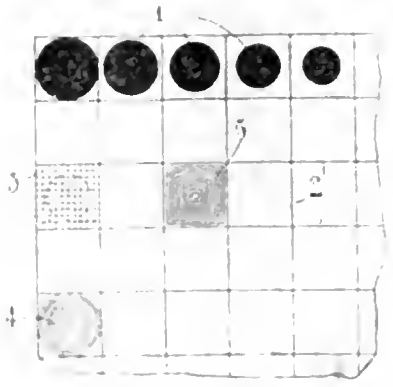
TELEGRAPHIC TRANSMISSION OF PICTURES.—No. 178,145 (October 14, 1920). The invention relates to the transmission of pictures by telegraphy; line or wireless, and is particularly concerned with pictures produced by process blocks, i.e., pictures built up of dots equally spaced, and of a size varying with the degree of light or shade.

A series of signals corresponding with the various sizes and positions of dots is transmitted and utilised at the receiving end to print mechanically dots of corresponding size and position whereby a reproduction of the original picture is built up.

The picture is first enlarged to such an extent as to enable each dot to be readily recognised according to its size by an operator, who then transmits signals corresponding with the various sizes of dots which occur in sequence in a row, these signals being used at the receiving end to operate mechanism whereby dots corresponding in size and position to those on the original picture are reproduced, thus building up a picture corresponding to the original.

The invention also consists in means for enabling the dots to be readily recognised according to which two series of lines at right angles to each other are superposed upon the enlarged picture at the transmitting end so as to form squares of such a size that each will enclose a single dot and also enclosing fainter lines which form smaller squares or other figures whereby the dots may be classified at sight according to the number of these smaller squares or the like which a given dot covers.

There is first made a reproduction of the picture to be transmitted to a scale sufficiently enlarged to enable the dots 1 (fig. 1) to be readily classified at a glance according to their size. To facilitate this classification there is superposed on the picture two series of lines 2 at right angles to each other so spaced that the squares thereby produced shall each contain one of the dots 1 constituting the picture. Lines 3 more closely spaced than lines 2 may be also faintly printed so as to produce a large number of squares within each of the larger squares, or instead of employing faintly marked squares we may place within the squares formed by the lines 2 concentric circles as indicated at 4 or a series of squares of uniformly increasing size as indicated at 5, or any other form of faint ruling which may be found convenient may be employed. By this means it is possible for an operator with a small amount of training readily to recognise the dots according to their size by observing the number of the faintly marked squares or the like which are covered by a given dot. The dots employed in forming the picture will be of a certain number, say ten, specific sizes, and on recognising that a certain dot belongs to one of these sizes the



operator would transmit a predetermined signal corresponding to the given size of dot. This signal may be received by any suitable form of mechanical receiver but modified, so that instead of printing letters, numerals or like characters, it will print a dot corresponding in size to that on the original picture. A series of signals may thus be sent, received, and the appropriate dots printed corresponding to the dots in one of the rows contained in the original picture. A second row of dots is then transmitted, and so on until the complete picture has been built up at the receiving end. This is then photographed and a process block prepared for reproduction of the required number of copies in the well-known manner.

The enlargement required for the transmission of the picture may be produced in any suitable manner, such for example, as by means of photography. For the sake of rapidity, however, it is preferred to employ an optical projection method whereby the picture is projected on a screen on an enlarged scale by an ordinary projection lantern, the squares containing the dots and fainter squares or other figures being also projected on the screen or printed thereon.

Automatic transmission of the signals may be attained by making an enlarged process block of the original picture, and utilising the raised dots thereon as electric contacts whereby signals corresponding to the various sizes of dots may be transmitted automatically, thus dispensing with the necessity of an operator at the transmitting end to recognise the various sizes of dots occurring in sequence and then transmit corresponding signals. Such a method of automatic transmission is diagrammatically illustrated in the specification.—John Cameron Grant, Holly Lodge, The Terrace, Barnes, Surrey.

The following complete specifications are open to public inspection before acceptance.

ARTIFICIAL LIGHTING.—No. 179,901. Artificial lighting devices for photography and the like. F. Demoulin.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, JUNE 5.

Bournemouth C.C. Outing—Whole Day at Picket Post and Burley.
Edge Hill C.C. Outing—Eastham, Carlet Park and Raby Mere.

TUESDAY, JUNE 6.

Bournemouth Camera Club. Hints, Dodges and Gadgets.
Sheffield Phot. Soc. Annual Meeting.

WEDNESDAY, JUNE 7.

Dennistoun Amateur P.A. Suggestions for Winter Syllabus.
Edinburgh Phot Soc. Annual Meeting.
Hackney Phot. Soc. Outing to Isleworth.
Rochdale Amateur P.S. "Self-Toning Paper." W. Lord.

THURSDAY, JUNE 8.

Hammersmith Hampshire House P.S. "Pictorial Photography in Practice." G. C. Weston.
Optical Society. Joint Conference between Ophthalmologists and Opticians on Spectacle Construction.
Sheffield P.S. Outing—Coal Aston to Hazelboro'.

SATURDAY, JUNE 10.

Bradford Phot. Soc. Outing to Fulneck.
City of London and Cripplegate P.S. Outing to St. Albans.
Dennistoun Amateur P.A. Outing to Wishaw.
Exeter Camera Club. Outing to Mamhead Park.
Hackney Phot. Soc. Outing—Zoological Gardens.
Hammersmith Hampshire House Phot. Soc. Outing—Hammersmith to Richmond.
Partick Camera Club. Outing to Whistlefield, Loch Long.
Rochdale A.P.S. Ramble with L. and C. Union.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, May 30, Mr. Furley Lewis in the chair.

The chairman declared open the the house exhibition of portraits by Mr. Pirie Macdonald, of New York.

Mr. E. J. Bedford delivered a lantern lecture on "Wild Flowers," illustrated with a large number of lantern slides, and many excellent examples of the lecturer's work in the Autochrome process. Mr. Bedford is a true lover and student of Nature, and his discourse was full of interest on account of his close observations of the wild flowers of the countryside.

A most hearty vote of thanks was accorded to the lecturer by acclamation.

CROYDON CAMERA CLUB.

Nothing draws so well at Croydon as the technical, and last week, despite the sweltering heat, a goodly number of members assembled to hear that past-master in camera design and construction, Mr. A. S. Newman, lecture on "The Evolution of the Hand-Camera."

This, he said, was primarily bound up with the introduction of the dry-plate. In those days cameras capable of being worked in the hand were invariably designated "detective," with the idea they would mostly be used for taking people unawares. Accordingly they took outward forms simulating, among other things, paper parcels tied with string, attaché cases, books, and even Bibles for use in church. The newspapers wildly stunted this new rôle in photography, and even Scotland Yard became imbued with the same idea.

Next, some foreigners went to the other extreme by introducing flamboyant hand-cameras designed to attract the attention of the multitude, and impress it with the importance of the operator exercising mysterious functions.

At this juncture in photographic history two classes of exposures only were known, one sort being time exposures with field and studio cameras, the other being "shutter" exposures with the detective type. No curiosity was exhibited or felt regarding the actual duration of these shutter exposures, beyond the fact that a shutter was considered the best which worked the fastest. Gross under-exposure was the order of the day. Naturally the subject attracted considerable attention among amateurs, and rarely did an evening pass at a photographic society without the production of the latest home-made and commercial shutters.

Apart from such primitive designs as the "drop-shutter," one of the earliest was the roller-blind due to B. J. Edwards and also to Mr. Cadett. The exceedingly stiff blind material, compulsorily used for lack of a better, sometimes refused to move at all in cold weather, and speeds always varied largely with changes of temperature. Kershaw's and Thornton Pickard's roller-blind shuttera followed. Contemporaneous were a whole series of mechanical instruments of varied design.

Grimstone's (the first to work between the components of the lens) started the lecturer on making shutters. His "Boiler" shutter, with speeds from 1 sec. to 1/100th sec., was the first to utilise pneumatic regulation dependent upon a variable air leak. This saw the light about 1884, and was followed by the Kodak "Barker," a pneumatic shutter dependent upon variable length of stroke, familiar to all in the "Unicum," and later models working on the same principle.

The introduction of the iris diaphragm gave further impetus to the use of hand-cameras, and a vigorous push was again imported when the anastigmat lens came on the scene. The first to appear was the Zeiss, series III A, working at f/6. It was of very unsymmetrical construction, which largely accounted for the complete absence of flare, even when dazzling sunlight entered the lens. Those fond of working dead against the light would find such a lens very useful, and although its manufacture had long since been discontinued, it might occasionally be picked up second-hand. He well remembered some lantern slides being shown at the Photographic Club in the Anderton Hotel days, the original negatives having been secured with one of these lenses and at the full aperture of f/6. Not a single soul in the room believed a statement made by the lecturer to this effect, owing to the exquisite definition shown from the centre to the corners, and after he had left all agreed he was the most magnificent liar that had ever appeared in the club rooms.

Mr. Newman then dealt with the evolution of hand-cameras as a whole, and pointed out that starting of medium size, they, in the course of years, grew larger and larger till some attained the proportions of a small portmanteau. Recently things had swung the other way in sympathy with a luxurious age. Too far, in fact, to which he attributed the deterioration of photography among the amateur rank and file. On the other hand, he did not wish to indulge in wholesale condemnation of pocket cameraa (being responsible for some himself), but less flimsy apparatus, something which one could hold firmly, undoubtedly conduced to better work.

The first box camera, he remembered, was due to Mr. J. B. B Wellington. It consisted merely of a cased ordinary camera with added fitments. Notable among early cameras was Fallowfield's "Facile." It produced excellent results, mainly owing to a simple shutter permitting only of moderate speeds. The first sheath camera owed its origin to Parfitt and Human, and was the pioneer of the magazine type with falling plates. Van Neck's reflex, Shew's folding cameras, cameras by Wellington, and many others designed on sane lines were then described by means of diagrams, including the first bag-changer due to the lecturer. A good word was also put in for the twin-lens camera, provided very close objects were avoided.

The first Eastman roll-holder, he said, was a splendid piece of mechanism. The first Kodak took a long length of film, and afforded a large number of circular pictures without reloading. A curiosity of this camera was that the lens was fitted right inside the shutter, not the shutter fitted to the lens, as is customary. Day light-loading came later. More modern cameras were then briefly discussed.

Much amusement was caused by the lecturer's frequent allusion to an individual who we may refer to as "Augustus," which was not his name. Mr. Newman said he had taken out many patents over many years, and soon after sealing Augustus was pretty sure to turn up. He was quite a nice and urbane individual, who sympathetically recognised the many difficulties and tribulations inventors experienced. Deplorable, therefore, was the fact that the latest patent invariably infringed one of earlier date held by the called It, say, Mr. Newman had been granted protection for a bag changer, then of a surety dear Augustus held a patent for a nose bag, a master one, covering every form and description of bag. Still he would not be hard, or insist on his rights, and everything could be arranged to the satisfaction of all merely by the payment of royalties. Sad for Augustus, he never touched Mr. Newman for a penny, but succeeded better elsewhere. Augustus is now no more and possibly is drawing commissions from departed photographers for powerful influence exercised in securing their admission to the best circles in their new sphere.

The discussion was brief, for the hour was late. Mr. E. A. Sa said in the past he had been struck with a critical point which often existed in pneumatically controlled between-lens shutters

[illegible] With the index set to 1/20th second, or thereabouts, speeds might vary 50 per cent. or more without apparent cause. Even with sector shutters, which did not act in this way, frequently a fractional movement of the index about this critical point resulted in a large variation in speed. A modern gear-controlled shutter in his possession also showed the same tendency.

Mr. J. A. Sinclair said thousands of such shutters had passed through his hands, and he agreed with the last speaker's remarks. On the general question of speed marking it was unfortunate that the top speed of the early "Unicum" was marked "1/100th sec." instead of 1/35th of a second, which was about its actual speed. Not to lose by comparison, many makers of later and faster shutters had been tempted to follow the bad example. A most hearty vote of thanks was accorded Mr. Newman for a very interesting and instructive lecture capitally delivered.

On a recent occasion a well-attended afternoon excursion of the Croydon Camera Club was held at picturesque Limpsfield. For the first time in history ladies participated, with one exception the wives of members, whose behaviour compared favourably with a small minority who had left their wives at home. In the most kindly protective way these temporary grass widowers entertained the only young single lady in the company. One or two diffident, but envious, bachelors present eventually, realising the hopelessness of their position turned in despair to taking inanimate, and far less attractive, pictures. Apart from this, the organiser, Mr. Walker, has plume himself on a very enjoyable afternoon, and on fully maintaining his supremacy in photographic disasters by leaving his camera in the tram on the forward journey. It has since been recovered, and he is accordingly several unspoilt plates to the good.

LANCASHIRE SOCIETY OF MASTER PHOTOGRAPHERS.

The fourth annual general meeting and conference were held at the Palatine Hotel, Blackpool, on May 17 and 18.

At the annual general meeting there was a good attendance of members, Mr. Arthur Winter (President) in the chair. The Secretary (Mr. W. H. Huish) submitted his report, and in doing so stated that in consequence of the last annual meeting not being held at the proper time, through labour troubles, the current year only commenced from October, therefore his report only covered a period of eight months.

The Committee during the short period they had been in office had dealt with several matters of importance to the members, and a number of applications for membership to the Society had been dealt with. He appealed to the members to continue to support the Committee in their effort to make the general meetings of the Society both interesting and profitable. He thanked them for the support they had given him as Secretary during his year of office, and hoped that they would extend the same support to his successor.

The President stated that he had received a communication from Mrs. W. T. Carter that her husband, Mr. W. T. Carter, the hon. treasurer, had been taken ill that morning and was unable to travel to Blackpool in order to submit the statement and balance-sheet. Mrs. Carter, however, had brought along the books and the hon. treasurer's statement, and he asked the members to be satisfied with the reading of the treasurer's statement and to postpone the passing of the balance-sheet until the next general meeting. The members agreed to this being done, and the statement was read and showed a credit balance of over £40.

The President then addressed the members at some length, and reviewed the work of the Society since he had been elected to that position. He stated that he had been pressed to continue in office for another year, but in consequence of pressure of business, brought about by the Preston Guild and illness in his family, he had reluctantly compelled to decide not to continue another year. He felt very strongly that the Society needed a president at the present moment who could devote a great deal of time to the work of the organisation, and he would ask the members to adopt the recommendation that had been sent forward by the committee, and that was that the vice-president (Mr. Charles Howell) should succeed him as president. At the conclusion of the President's address, Mr. Fred Read, in a few very well-chosen words, proposed that Mr. Charles Howell be elected president. This proposition was seconded by Mr. Bamber, and carried unanimously. There being no further nominations, Mr. Charles Howell was duly elected [illegible] and placed in the chair by Mr. Arthur Winter.

Mr. Charles Howell, in thanking the [illegible] for the [illegible] they had done him by [illegible] him to [illegible] at he would at all times take a deep interest [illegible] Society and promised to do his best to [illegible] his worthy predecessor. [illegible] then asked [illegible] president, Mr. [illegible] Rochdale, [illegible] Mr. R. [illegible] be [illegible] adopt [illegible] unanimously.

The President [illegible] Mr. [illegible] carried to [illegible] for [illegible] Winter proposed [illegible] was seconded by Mr. Read and carried [illegible] tion of [illegible] by [illegible] the secretary [illegible] elected on the committee of management [illegible] (Barrow), [illegible] (Rochdale), W. [illegible] W. Herbert [illegible] Caro (Eccles), [illegible] (Wigan), Percy Guttenberg (Manchester), Do[illegible] A. Walmsley ([illegible]ton), [illegible] (Blackpool).

At the conclusion of the election of officers, a long discussion took place on the question of the proposed [illegible] been postponed, and the President called upon Mr. [illegible] to give his report with regard to the matter. At the conclusion of that report, Mr. Bamber promised £100 towards the guarantee fund, so that the exhibition [illegible] held next autumn, and made several very valuable suggestions with regard to it. Mr. Feloy proposed that the exhibition be held under the auspices of the Society. This proposition was seconded by Mr. Caro and carried unanimously. Mr. [illegible] then proposed that Mr. Bamber's kind offer be accepted, and that Mr. Bamber be on the committee of management, and the details of organisation be left to this committee. This proposition was seconded by Mr. Winter and carried.

At 4.30 p.m. a lecture by Mr. C. Pollard Crowther, F.R.P.S., on the "Psychology of the Studio" was given. The President, on introducing Mr. Crowther to the members, said that they were indebted to the [illegible] for having allowed him to visit Blackpool in order to give them the value of his wide experience. Mr. Crowther's lecture was both interesting and instructive, and the happy manner in which he dealt with his subject appealed to those present. At the conclusion of the lecture, which lasted one hour and which was illustrated with some very good slides, Mr. Crowther was thanked by the President, on behalf of the members, and those present showed their appreciation in a true Lancashire style.

At 7 p.m. the annual dinner was held, when the guest of the evening was Mr. A. Swan Watson, the President of the P.P.A. He was supported by the Secretary, Mr. Alfred Ellis. At the conclusion of a most excellent dinner and the Royal toasts, Mr. N. S. Kay, [illegible] President, made a very happy speech in submitting the toast of "Our Guests." It was, he said, the first occasion on which the Society had been honoured with the presence of a president of the P.P.A. at their annual function, and he expressed a wish that it would be the means of cementing the friendship which already existed between the two organisations. Mr. Kay also touched upon the Congress to be held in London in the autumn, and hoped that every member of this Society who could do so would attend that conference.

Mr. A. Swan Watson, in responding to the toast, amused the company with some very good Scotch anecdotes. He stated that he appreciated the honour that had been done him by inviting him to that function, and he endorsed the sentiment that had been expressed by Mr. N. S. Kay with regard to the two organisations. He was greatly in favour of the holding of these conferences, and he had some very happy recollections of the conferences that he had attended of the P.P.A. in the years gone by. He wished the Society of Master Photographers every success, and hoped that as many as possible of them would journey to London for the Congress, so that they might [illegible].

Mr. Arthur Winter [illegible] the toast of the President, Mr. Charles Howell, [illegible] Mr. Howell [illegible] himself in the work [illegible] Mr. Howell had many [illegible] as far away as Chatham [illegible] he was not present [illegible] his year of office.

and asked the members to support their new president in the same way that they had supported him.

Mr. Howell, in responding, stated that he did not pose as a public speaker, but he would do his best as a worker to fill the position they had been good enough to place him in as their president. He invited the co-operation of all the members in the work of the Society, and he would impress upon them the necessity of letting him or the secretary know of any grievance they might feel they had, as both he and his committee were desirous of the co-operation and assistance of every individual member, and if they had any suggestions to make he would be very pleased if they would send them along.

The toast of the British Photographic Manufacturers' Association, Ltd., was proposed by Mr. W. H. Huish. In proposing this toast, Mr. Huish regretted that none of the officials of the Association were present to respond. A number of the firms connected with the Association had received circulars with regard to the function, and it was the intention of several to be present, but, unfortunately, at the last moment they were prevented from doing so. Several of the manufacturers' representatives, however, were present at the dinner that night, and he welcomed them on behalf of the Society. In doing so he suggested that if the two sections of the trade could only see their way to set up a joint committee in order to deal with matters affecting the industry, he thought it would be to the mutual advantage of all concerned. He sincerely hoped that if the committee of the Society decided to organise an exhibition for next autumn the support of the British Photographic Manufacturers' Association would be given to that exhibition.

Mr. V. L. Wahltuck (A.P.M., Ltd.) was called upon to respond, and in doing so stated that he was surprised to hear from Mr. Huish that so few had replied with regard to this function. He felt sure that had they received personal invitations instead of a circular letter the Manufacturers' Association would have been well represented. He differed from Mr. Huish in some of the opinions he had expressed; at the same time he appreciated the honour they had done him by inviting him to that function, and he sincerely hoped that in the near future Mr. Huish's suggestion of co-operation between the two sections of the trade would be brought about.

In the absence of Mr. W. T. Carter, the toast of "The Ladies" was proposed by Mr. R. H. Gresswell, and was responded to by Miss Flemming, F.R.P.S.

"The Society of Master Photographers" was proposed by Mr. Alfred Ellis, Secretary of the P.P.A. He stated that it gave him very great pleasure indeed to be there that evening as a past-president of the P.P.A. and its present secretary. He had for many years been associated with the Association; as a matter of fact he was the first secretary, and he had at all times looked upon the setting up of these local Associations with favour. He was glad to see that the Society of Master Photographers had been so successful, and he hoped that in the future the good feeling that had prevailed in the past between the two organisations would continue. He touched upon some very interesting past history of the P.P.A., and invited the co-operation of all photographers in order to make the Congress which will be held in London in September next a success.

The toast was received with enthusiasm by the visitors, and the President, Mr Charles Howell, suitably responded.

During the evening a very excellent programme of music was provided by Mr. Chris. Howell, son of the president, and each musical item was very much appreciated. Mr. W. H. Huish, secretary, acted as toast-master.

On the following day at 3.30 Miss Flemming, F.R.P.S. (of Nottingham) gave a very excellent paper on "Child Photography," illustrated with some very excellent lantern slides.

At 6.30 a demonstration was given by Mr. C. Pollard Crowther, F.R.P.S., on the "Making of Portraits." Mr. Crowther had already made a very excellent impression on the members, and although this was the last function of the Conference, a very large number remained over in Blackpool in order to hear Mr. Crowther once more. At the conclusion of the demonstration the president thanked Mr. Crowther and all those who had assisted in making the Conference such a great success, and he sincerely hoped in the near future they would all meet once more and have just as good and profitable a time as they had had during those past two days.

News and Notes.

SAURIAN MOUNTING PAPER.—A reader wishes to know the firm supplying a stiff art mounting paper, made in two shades, and supplied under the name of "Saurian." Replies, addressed to D. M. F., c/o the Editors, will be forwarded.

THE CLUB PHOTOGRAPHER.—Members of the Borough Polytechnic Photographic Society contribute the staple contents of the June issue of our little contemporary. One paper describes the use of a card index system in the management of a photographic society.

HOUGHTONS PROFESSIONAL BULLETIN for May publishes an article on the Photographic Fair and on the American professional portraits by Alexander Mackie. The issue also contains illustrated particulars and prices of Messrs. Houghtons' equipment for D. & P. work.

THE "ROYAL MAGAZINE," published by C. Arthur Pearson, Ltd., may be brought to the notice of their customers by photographers just now, since it is offering £50 for the photograph of the prettiest feminine reader. £5 will be awarded to the photographer who takes the prize-winning photograph. Particulars of the competition, which closes on June 22, are given in the June "Royal," just published.

CRITERION FILM COMPETITION.—In addition to their monthly contest, Messrs. Criterion, Ltd., have organised a competition for prints from negatives on Criterion roll-film, in which prizes of £15, £10 and £5 will be awarded to amateurs. In addition, the dealer supplying the spool which gains the first prize will receive stock of Criterion manufactures to the value of £10. The competition closes on September 1. Entries should be addressed to Criterion, Limited, Stechford, Birmingham, and should be marked "Film."

A FRENCH DICTIONARY OF PHOTOGRAPHIC CHEMICALS.—A correspondent, writing in reference to the reply given to "R. G." in "Answers to Correspondents" last week, says: "As French is easier for the average Englishman to read than German, your correspondent may be interested to know of a small paper-covered dictionary published by Charles Mendel, Rue d'Assas, Paris. The title of the work is 'Les Produits Chimiques Purs en Photographie: Leur Nécessité; Leur emploi; Leur contrôle.' The author is Dr. Camille Poulenc, but the price is not stated."

MARSHALL ENLARGEMENTS.—Messrs. Marshall & Co., Mansfield Road, Nottingham, whose trade work for photographers we have often been able to commend, send us a copy of the illustrated catalogue, which they have just issued, showing the styles of enlargement which they offer. Prices have been considerably reduced, remarkable value being offered in monochrome and coloured enlargements. Messrs. Marshall undertake all descriptions of trade work including copying, contact printing, and miniatures, and have recently added a department for the trade development of amateurs' film negatives. The list is obtainable free by bona-fide photographers and dealers on application.

THE PHOTOGRAPHIC CONVENTION.—The thirty-second meeting of the Photographic Convention is to be held at Shrewsbury, from July 3 to 8, under the presidency of Mr. C. B. Clifton, supported by Mr. C. H. Bothamley, retiring president. A full programme of excursions has been arranged, including visits to the picturesque towns of Ludlow and Much Wenlock. During the week Mr. W. L. F. Wastell will deliver his lecture, "A Loon in London," and there will also be a lecture on "Old Shrewsbury." The Shropshire Photographic Society, newly formed under the presidency of Mr. Martin J. Harding, is lending generous help in the arrangements for the week. Mr. C. J. Poole, of 51, Hill Crescent, London Road, Shrewsbury, is the secretary of the local committee. It is hoped that a large gathering will assemble at Shrewsbury and make the week a repetition of the pleasant functions of former years. Applications for membership and requests for further particulars should be addressed to the general secretary, Mr. F. J. Mortimer, 56, Leigham Court Road, Streatham, London, S.W.16.

A NORTHERN PROFESSIONAL PHOTOGRAPHERS' SOCIETY.—At a meeting of the professional photographers of Middlesbrough and the surrounding towns, held last week, in the Scottish Café, Middlesbrough, it was decided, upon the motion of Mr. Harold Hood, of Middlesbrough, seconded by Mr. Greenwood, of Stockton, to form the North Yorkshire and South Durham Professional Photographers' Society to further the interests of the professional photo-

graphers in the district. Mr. Heldsworth, of Hartlepool, was elected chairman; Mr. H. Hood, vice-chairman and treasurer; Mr. Ball, jun., Stockton, secretary; and Messrs. Parry, Greenwood, Bunting, Richardson, Wood and Davy a committee. Rules were also approved and other details settled. Although the meeting was full of enthusiasm, it was decided to call an adjourned meeting, and the Secretary was instructed to make special efforts to secure the largest possible attendance so that the rules and general procedure might have the approbation and confirmation of as many professional photographers in the district as possible. At the adjourned meeting the actual details of a minimum price scale for technical and other work are to be fully discussed.

A Press Photographer's Problem.—Writing to the editor of "The Journalist" (the organ of the National Union of Journalists), a correspondent, using the nom-de-plume of "Picture Maker," says: "I gather that the Leeds Branch is to consider the question of a staff photographer supplying London papers with photographs, it is believed, at the request of his editor, 'a local free-lance being willing.' Providing that the staff photographer is allowed a reasonable commission on sales is there anything unfair in this arrangement? In some districts it has obtained for years. When negatives are taken for an employer by a salaried man, the right to dispose of them in any way he thinks fit is clearly vested in the employer. There is no legal obligation even to pay commission. A 'free-lance' man can hardly have ground for complaint if he takes his pictures simultaneously with the salaried man and promptly dispatches his negatives to an agency. He will be 'in first' easily. It would be objectionable for an employer to offer negatives at less than the current price for pictures, of course. If the salaried man's negatives are of subjects which the 'free-lance' man has not covered there is no grievance whatever that I can see."

Mr. F. A. Free, of Davenport, Iowa, to whom the award of the silver cup was made in the recent exhibition of American portraiture at the Photographic Fair, has written to Mr. Arthur C. Brookes a letter which we are glad to quote, particularly on account of the community of spirit between photographers in the country and the United States which it exhibits. Mr. Free writes:—"I received your letter yesterday, and wish to say that I appreciate the honour more than I can say, so much more on account of the fact that I had forgotten that there was a cup offered. I sent my pictures because I believe in an exchange of pictures and ideas internationally, and especially among English-speaking nations, and I sent mine mainly to help give a good general idea of American professional pictorial photography.

"Our national Association was in session at Kansas City when your cablegram was forwarded to me, and many of the exhibitors were there, and when my winning the prize was announced, they gave me a great ovation. They thought it quite the biggest honour ever received by an American photographer. I have received numerous medals and certificates on my work in the past, and none can compare with the advertising value and standing that the winning of this cup will give me in the profession.

"I will be anxious to receive this cup, which you say will be shipped immediately following the Fair. I wrote Mr. William Crooke telling him of my appreciation, and some day I expect to be over there to see what our English cousins are doing."

BLUE SCREENS IN COPYING STAINED PRINTS.

To the Editors.

Gentlemen,—With reference to your answer to "J. H."—paragraph three in this week's "Answers to Correspondents"—the following may be of interest. Some years ago an old P.O.P. print was brought to me to be copied, the whites of which had turned a decided yellow; furthermore, there was an ink stain on the dark (purple) part of the print, which would not yield to ordinary treatment. A negative on an ordinary plate gave a very poor result, the ink stain showing very prominently. At that time I was experimenting in the making of colour screens for three-colour work, and had two or three blue screens by me, one of which I selected, and, again using an ordinary plate, made a second negative. The result was that the whites were fully restored, a somewhat expected result, but I was rather surprised to find that no trace of the ink stain appeared in the second negative.

I have frequently used blue screens for copying stained and spotted prints with very satisfactory results. In this respect I have found that correct screens for colour work are not always successful, different stains requiring different screens to entirely eliminate them.

May I give one other instance? A print that appeared to be quite perfect was brought to me for advice. A copy was particularly desired, but two or three attempts to obtain one had proved unsatisfactory. At each attempt numerous clear spots had appeared in the copy negative all over the white portions of the subject. Examination in good daylight showed that the print was covered with faint yellow spots. Copying through a blue screen cut these spots out entirely.——Yours faithfully,

Cyril Venning.

Brook St. Hill, Brentwood, Essex.

THE RUSSELL EFFECT.

To the Editors.

Gentlemen,—The Paris notes of your esteemed French correspondent, M. L. P. Clerc, in your issue of May 19, 1922, contain mention of a "New example of the Russell effect," by M. Bardier. This refers to lignite and jet. An account of the action of these substances on the photographic plate appears in the two following papers by Russell:—

"The action of wood on a photographic plate in the dark," Trans. Royal Society, Series B, Vol. 197, p. 285. "The action of resin and allied bodies on a photographic plate in the dark," Proc. Royal Society, B, Vol. 80, p. 384.—Sincerely yours, Olaf Bloch.

Ilford, Ltd., Ilford, London.
May 24.

DO ACID FIXING BATHS CAUSE BLISTERS?

To the Editors.

Gentlemen,—An experience I had during the heat wave of last week leads me to ask the above question. Last Tuesday (May 23) was the hottest May day we have had for generations—in London at any rate. Having many plates to develop I thought it advisable to take extra precautions against frilling, and frilling I did stop right enough, but in place of frilling I got blisters.

For many years I have been in the habit of using the acid-alum-sulphite fixer and hardener, as given on page 454 of the current "Almanac," namely: Soda sulphite, 4 oz.; glacial acetic acid, 3 oz.; alum, 4 oz., and water to 20 oz. This is kept as a stock solution, 2 oz. of it being added to each 20 oz. of the normal hypo solution. This solution has been a good servant for many years, but last Tuesday, when the darkroom and solutions were so very hot, I decided to use 4 oz. of the stock acid bath to one pint of normal fixer—double strength. I ought not to have doubted the efficacy of the normal strength, but I did, and after the negatives had been in the bath for about five minutes some thousands of pimples and blisters appeared on the gelatine surface of many of the plates. Two makes of plates were developed and fixed, but the defect appeared only on one make, the extra dose of acid-alum solution apparently not suiting them. I say "extra dose," because some further exposures on the plate fixed in a normal bath showed no defects, hence the putting of the blame upon the extra strong acid-fixer.

You may be able to suggest some other cause of the annoying defect—the negatives are quite ruined—having perhaps some experience of it? Should you think as I do that the excess of acid and alum caused the blisters, it would be wise to caution your readers concerning the following of instructions, pointing out the danger of increasing the strength of certain fixing and hardening baths.

Many years ago, when using formaldehyde as a hardener, I once used it too strong, the films stripping like pieces of horn from the plates after drying, but I never expected an acid-fixer and hardener to cause blisters.

The blistered plates, it may be mentioned, were developed in a normal hydroquinone-metol solution.—Yours faithfully,

C. L. KESTLETON.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S J.—The secretary of the Photographic Dealers' Association is Mr. E. H. Ayling, Messrs. Horne's Camera Mart, New Broad Street, London, E.C.2.

M. M.—So far as we know, cases of the kind in which Daguerreotypes were mounted are not now made, but we have no doubt that a firm of makers of miniature cases, such as Messrs. G. and E. Russell, 262, Northfield Road, King's Norton, Birmingham, could make imitations of them

B. R.—The by-laws respecting photography on the foreshore vary in different places, but, as a rule, the rights are sold each year by the corporation or local authority, and we think the latter would have the power of preventing photographs being made on the beach for money by anyone, whether by appointment or otherwise.

G. C.—Metol in combination with pyro is more prone to give stain in the negatives than any other mixed developer. If you must choose this combination, we suggest that you take an ordinary pyro-metol formula, dissolving the chemicals in three or four times the quantity of water, and use, say, two or three times the amount of sulphite. But for general purposes the pyro developer, as directed in the Houghton catalogue "Trade Developing," is the best for amateur films.

W. R.—The arrangement you suggest will work quite well, although the exposures will have to be much longer than if a condenser were used. In your case we think you would find it better to have two lamps of 1,500 c.p., placing one at each side of the opening with the reflector parallel with the negative holder. This will give more even illumination and probably shorten the exposure. It is desirable to use a rapid flat field lens when working by reflected light.

M. D.—Provided the tank is well rinsed after the use of the fixer it can be used again for the developer without any ill effects. We don't think that coating it with anything is really necessary as a protection against the acid hypo solution, provided that the solution remains in the tank only for such comparatively short periods as the tank is in use. But considering, as we imagine, that you will often be working when there is not a plentiful water supply, we think you would be well advised to take a separate tank for fixing.

H. S.—We have referred your question to Mr. Ermen, who replies as follows, and adds that pure amidophenol and amidocresol are supplied by the British Dyestuffs Corporation, even in the smallest quantities. The free base of metol is quite freely soluble in water, and if the solution is at all warm, is liable to separate, on the addition of alkali, in the form of transparent oily drops, instead of as a crystalline, white, flocculent precipitate, as do amidophenol and amidocresol. It is thus not at all easy to know when to stop the addition of caustic soda, and one is very liable to overstep the mark. Furthermore, in the rodinal type of developer, metol is in no way superior to amidophenol, and not as active as amidocresol, whilst it is considerably more expensive

H P.—A matt surfaced bromide print requires no preparation for colouring if it has not been handled with greasy fingers. You were quite wrong to put French chalk on the surface, as this is repellant of water. Gum is not necessary, except to match the surface of glossy paper or to give depth to the shadows of a matt print; it is rarely used now. If a print is greasy, it may be washed over with a little diluted ox-gall, or even a little soapy water, which should be well wiped off with cotton wool. Newman's sizing preparation makes the colour work very sweetly on almost any paper. You can get it from Newman and Co., artists' colourmen, 24, Soho Square, London, W.1. So far as we know, there is no book now to be had on the subject. Winsor and Newton used to publish a shilling manual on colouring photography, by Rintoul, but it has long been out of print.

L. J. B.—The scummy appearance on the negatives is due to the use of the alum bath and is rather apt to occur in hot weather here, although plates have been remarkably free from liability to show this defect for many years past. Moreover, owing to the superior emulsions, the alum bath is now very little used. We think you will have to try to dispense with alum if you possibly can; that is to say, if the defect is frequent. Instead you could use a bath of about one part of formaline in 20 parts of water before development, or between development and fixing. The Ilford Tropical hardener, sold by Johnson and Sons, 23, Cross Street, Finsbury, London, E.C.2, is a very good means of avoiding softening of the gelatine in tropical climates, and in our experience is without tendency to produce these scummy markings. We are sure that if you discontinue the use of alum you will not be troubled with them further.

P. H.—You certainly ought to wash the films reasonably well, otherwise, so it seems to us, you are only making trouble for yourself in undertaking this work. Surely it is not impossible to fit up a tank about 1 ft. square, and say 4 ft. in depth, in which half a dozen film bands can be suspended at a time and washed in a current of water? Half an hour's washing in this way should be satisfactory If you use an ordinary large domestic bath, films would never get a complete change of water, but we daresay the great bulk of the hypo would be removed from them, say, half an hour's soaking. The residue could no doubt be removed completely and without harm by passing the film bands through a weak solution of potass permanganate. You should use a solution rendered just pink by adding a few drops of permanganate solution to plenty of water, adding more of the stock solution as the colour is discharged by the hypo in the films. In any case, the solution in which the film bands are thus treated should be frequently renewed in order to avoid the tendency for the permanganate to produce brown stains, or a general brown stain. A weak solution of sodium bisulphite will clear off any such stain

SUMMARY

Many hints and suggestions in the photography of children are contained in a paper read by Miss Flemming, F.R.P.S., of the Freckleton Studio, Nottingham, at the recent Blackpool Congress of the Lancashire Society of Master Photographers. (P. 337.)

The final chapter of the series by "Pelham Swinton" on the business side of professional photography concerns itself with the practical and persuasive (or legal) methods to be taken in the collection of outstanding accounts. (P. 335.)

An example of the opportunities for professional cinematography is the subject of a paragraph describing a film taken recently by Miss Olive Edis of a notable wedding. (P. 333.)

An exhibition of remarkable interest is that of portraits by Mr Pirie Macdonald, now being held at the house of the Royal Photographic Society, 35, Russell Square, London, W.C.1. (P. 343.)

Preliminary particulars are published of the forthcoming congress of the Professional Photographers' Association. The entry form for the exhibition of portrait and commercial photography is now obtainable. (P. 333.)

Photographs of house property might be much more attractive than they usually are; whilst there is still much property changing hands, there are many opportunities for the supply of photographs which present houses in their most attractive aspects. (P. 334.)

The features of apparatus for enlarging without the use of condensers are the subject of a leading article, in which the sources of light and construction of these enlargers are dealt with. (P. 334.)

The first portion of the valuable review by Mr. F. F. Renwick of recent progress in photographic manufacture and in methods of photographic investigation and measurement will be found on page 340.

At the adjourned hearing of the Board of Trade inquiry under the Safeguarding of Industries Act, respecting the sale of German scientific goods in the United Kingdom, arguments on behalf of German firms were presented by Mr. Inskip, K.C., who called evidence by agents for German manufacturers. (P. 342.)

One or two of the points requiring to be kept in mind in the use of warm black development papers are mentioned in a paragraph on page 334.

We regret to record the death of Mr. J. Crawys Richards, one of the leaders in the early movement in pictorial photography, and author of a manual on the gum-bichromate process. (P. 346.)

The Traill-Taylor lecture is to be delivered in October next by Dr. R. S. Clay, who will take as his subject "The Development of the Photographic Lens from the Historical Point of View." (P. 346.)

EX CATHEDRA.

The P.P.A. Congress.

A preliminary circular outlines the features of the Congress to be held in the Princes Galleries, Piccadilly, London, W., from September 11 to 15 next, by which the Professional Photographers' Association will celebrate the twenty-first anniversary of its foundation. There will be an exhibition of apparatus with demonstrations by experts, lectures and demonstrations on posing, electric lighting, business methods, etc.; visits to works of photographic manufacturers and to some of the London studios. One evening of the Congress is to be set apart for assistants, whilst an announcement of much interest is that which relates to the attendance of American, Canadian and Continental photographers. Mr. Pirie Macdonald, a host in himself, has definitely promised to take part in the Congress throughout the week. An international exhibition of professional portraiture is being organised and will, it is hoped, include examples of the work of leading portraitists in all parts of the world. Representation in this exhibition is obtained by open competition, and the form of entry is now obtainable on application to Mr. Alfred Ellis, 2, Vinery Villas, Hanover Gate, London, N.W.8. The exhibition will include also a section for commercial and technical photography, and silver and bronze medals will be awarded in both sections. It is evident from the above programme that the Council of the P.P.A. are leaving no stone unturned in their efforts to make the Congress of the greatest possible value to professional photographers. Full particulars will be published shortly, but in the meantime our professional readers in all parts of the world should support the Council in the one way which is open to all of them, namely, the sending of their work to the exhibition, the last day for receiving which (together with the entry form) is August 31.

* * *

Cinematograph Portraiture.

From time to time we have pointed out the opportunities which present themselves for the employment of a cinematograph camera by photographers in the circumstances in which most of those in provincial towns are situated. Nevertheless, we have heard very little in lead of enterprise of this kind, and, therefore, we were very interested in having our notice drawn a few days ago to a piece of cinematograph work undertaken by a versatile woman photographer, Miss Olive Edis. We witnessed the showing of a film which Miss Edis took about ten days ago of the village wedding of the son of Sir Henri Deterding, the oil magnate. The ceremony took place in the little Norfolk village of Holt, where Miss Edis filmed the story in a way which unquestionably gave the film an interest which will make it a prized possession by those who were the chief actors in it. The incidents began with the home of the bride's mother, finished with the country estate of the bridegroom, and included a

number of humorous passages, incidental to the high spirits which find expression on the occasion of a marriage, and particularly of one having certain romantic features. There are scores of weddings taking place every month among people to whom the cost of acquiring a cinematograph record of the incidents is a trifling amount. Yet it may be questioned whether the thought of adding this business to that of making the stereotyped groups and other still photographs occurs even to those who actively canvass for wedding business. But they, in consequence of being on the spot beforehand, are better able to make the arrangements than is the operator who comes down in a hurry from the headquarters of a topical cinematograph firm. Miss Edis is to be congratulated on a piece of enterprise which is certainly the first of the kind which has come under our immediate notice.

* * *

Warm-Black Bromides. In the use of the warm-black grades of bromide, so popular to-day, photographers who have not been getting results of the quality they would like will do well to examine their negatives with a view to ascertaining if they have sufficient contrast to give the best results. A negative that will give a good print or enlargement upon one of the "hard" grades of bromide, and a fairly good result upon one of the ordinary rapid grades, must not be expected to give the finest result upon a warm-black paper. Probably its greatest defect will be as regards the colour of the print, which, instead of being a pleasing warm brown black, will be of a dirty black colour. One maker of these warm-black bromide papers emphasises the importance of a suitable negative, advising one of vigorous quality, such as will give a good print upon P.O.P. Those who have been disappointed with their previous results, when compared with the manufacturer's specimens, will very likely find that it is the density of their own negatives that is at fault. Another point often overlooked is that development should be carried to finality in order to get the best result as regards colour of the prints. More or less random exposure, followed by rapid development, which is the practice of many slipshod printers, will not do with warm-black bromides. If, however, a print has been over-exposed and not fully developed, and is consequently a poor colour, treatment with the chromium bleacher, followed by full re-development with amidol, will be found to work wonders.

* * *

Photographs of Houses. The individual who is engaged in the harassing task of trying to find another place of residence must come to the conclusion that, on the average, owners and would-be sellers of houses are very badly served by the photographs which they use for showing what a property is like. Undoubtedly this is largely their own fault and arises from the employment of the travelling photographer who goes about offering at a cheap rate postcard photographs of houses. These productions, of which a good many have happened recently to come under our notice, are commonplace to a degree. Little is done to show a house in its best aspect, and it is often instructive to contrast the bald appearance (in the photograph) with the often picturesque character which a house has when actually seen in its surroundings. Often, too, the photograph is taken in dull weather, so that the character of the building suffers from the lack of light and shade in the photograph. Whilst there is still so much buying and selling of houses going on, there is the opportunity for photographers to give more thought to this kind of business. An advisable preliminary is to prepare a few specimens in which sunshine plays its enhancing part in showing a house to advantage, and in which also an endeavour is made to present adequately the setting of a house when this is in fairly open surroundings. To many a prospective purchaser a picturesque glimpse of a house obtained from a point in the garden is more persuasive than the most detailed more conventional picture.

ENLARGING WITHOUT CONDENSERS.

WHILE the ordinary type of enlarging lantern with its large condensers still holds pride of place with most professional photographers, signs are not wanting that this position is being challenged by various devices for illuminating the negative in a less costly manner. Not alone the cost of the apparatus but the quality of the work produced has contributed to the development of condenserless enlargers, for it is generally acknowledged that defects in the glass or film, or the marks caused by retouching medium, are less obtrusive in the enlargements when the condenser is dispensed with.

There are two main classes into which such enlargers can be divided, one being designed for use with reflected light, while the other utilises one or more diffusing screens between the lamp and the negative. There is no new principle or discovery involved in their construction, which has only been rendered of practical value by the invention of mercury vapour and gas-filled incandescent lamps. Arc lamps have been used principally by trade enlargers, but they are too clumsy and troublesome to be used in the average dark room.

A typical model of the first class is found in the Robinson enlarger, marketed a good many years ago by Marion & Co. It consisted of a rather shallow box, having in one side a nest of carriers for various sized negatives, while on the side facing it was a whitened reflector. Between these two sides were four or more incandescent electric lamps, according to the size of the apparatus Suitable screens were arranged to prevent any direct light from reaching the lens. An ordinary front-focussing camera with lens completed the arrangements. This apparatus, although sound in principle, did not win popular favour, on account of the long exposures which were found necessary. A slight yellow stain or excessive density of a negative made the production of a print in a reasonable time practically impossible. The introduction of the half-watt lamp with its greatly superior actinic value has altered this, and enlargers of this type become of practical value. Other models of this type have curved reflectors, but although this modification may slightly reduce the exposure, there is a certain risk of uneven illumination of the negative.

The other type of enlarger has many points to recommend it, not the least being compactness and lightness. In its simplest form it is to be found in many cheap postcard studios, where one finds a simple arrangement of perforated shelves, one carrying a small portrait lens, the next the negative, one above that a sheet of ground glass, while above all is a small half-watt bulb or even an inverted incandescent gas burner. From this to the Kodak or Overton automatic focussing enlargers is a far cry, but the difference is in detail and not in principle. The new enlargers have their lamps fitted into a metallic chamber which is lined with a reflecting material, either white japan or silvered glass, and closed with one or more thicknesses of ground glass. By careful arrangement of the reflecting surfaces the illumination is rendered more equal, and the exposure reduced to a point at which it becomes comparable with that required when a condenser is used.

Another very efficient form of enlarger is that fitted

with the mercury-vapour lamp, the tube being bent into the form of the letter M or, as it is sometimes called, a gridiron. The peculiar form of the tube gives very even illumination over a large area, and for this reason these enlargers are especially suitable for trade work where negatives up to 12 × 10 or larger have to be dealt with. An interesting feature is the fact that two enlarging cameras can be worked with one mercury-vapour lamp, which is then provided with two diffusing screens and sandwiched between the negative holders.

An important characteristic of enlargers of these types is that no adjustment of the light is needed for different degrees of enlargement. This renders the automatic focussing enlargers possible, as an additional movement for this purpose would have added enormously to the difficulties of construction.

Those of a constructive turn of mind, as are the majority of photographers, will find considerable interest in the designing of enlarging apparatus on the lines described above. Where the electric current is available the use of half-watt lamps makes the task an easy one; in other cases the inverted incandescent gas burner is by no means a bad substitute. Experiments may be made with a single lamp with a many-facetted reflector (a popular method in America), or with grouped lamps in the frustrum of a pyramid the sides of which are silvered glass. There is to be had at some ironmongers an octagonal pyramidal reflector, lined with corrugated glass, which, with a single half-watt lamp and a sheet of ground glass, illuminates a half-plate negative under somewhat trying conditions.

A few hints may be given to would-be constructors. Do not use finely ground glass for diffusers; the coarser the grain the better the diffusion, provided that the nearest surface is far enough from the negative for the grain to be out of focus. See that there is sufficient ventilation in the light-chamber. Use a rapid flat-field lens, since there is no concentration of light as when using a condenser. Choose a vertical model in preference to a horizontal one; it is easier to build and also to work.

THE BUSINESS SIDE OF PROFESSIONAL PHOTOGRAPHY.

[The subject of the last of the chapters on the business side of professional photography, namely, the collection of customers' accounts, provides our contributor, "Pelham Swinton," with special opportunities for exhibition of his mordant wit and shrewd insight into human nature. Previous chapters of the series have been:—"The Economic Position of the Photographer" (April 28); "The Photographer and his Client" (May 5 and 12); "The Photographer's Clerical System" (May 19); and "The Photographer's Costing System" (May 26). We think that those who may have overlooked any of the previous papers will be grateful to us for these references.]

V. *(continued)*—THE ART OF ACCOUNT COLLECTING.

Suppose, therefore, that a certain photographer sends out his accounts every month, but that a batch of ten accounts incurred in January have reached their fifth month of rendering without having been paid. If the divided card ledger previously described is in use, these ten accounts will all conveniently be grouped together. They have each been rendered four times without response, and we shall commence with the polite presumption that each of these ten persons is careless or forgetful, and that the accounts have been innocently overlooked. We therefore render them all once more, but accompanied by the following letter:—

> "Dear Madam,—We find that the enclosed account has been permitted to fall somewhat in arrear. We know how easily such things are overlooked, and that it is necessary merely to call your attention to the fact.
>
> "Yours faithfully,"

No sane person could cavil at such a letter, yet it performs all its purpose. The sole object in the case of persons who are really only neglectful, is to awaken their attention, which has been gently lulled to sleep by the monotonous influx of statements—not only from one's own firm, but from many others also. This account may possibly be the only one accompanied by a letter; moreover, it is sealed and bears a twopenny stamp—a fact which in itself will arouse interest. The opening sentence must be fairly pointed, in order to administer the necessary pin-prick; and any slight annoyance which this might cause is carefully smoothed over by the friendly and human tone of the succeeding sentence. The whole is rounded off with the suggestion that the firm is aware that the tardiness of payment is due in no way to lack of honesty or morality, and thus appeases, and perhaps flatters the recipient.

We shall suppose that this results in five out of the ten accounts being paid. The remaining five people must be either in financial difficulties, or persons who are well practised in the art of debt evasion. One thing is certain regarding the former class, that, if a letter be written to them regarding their account, an opportunity is thus given them to reply and honestly to state the cause of the delay. If no letter be sent them, they will not feel so inclined to confide their circumstances to the firm. On the other hand, the photographer may receive letters from members of the other class also pleading monetary troubles, and accompanied by many delightfully friendly little touches. Let him beware of such letters. The writers are only rascals, and it is usually not very difficult to distinguish the genuine from the hypocritical. Nevertheless he may be mistaken, and he must apply a test.

For all who write such letters, to whichever class of debtor they belong, the great test of genuineness and honest desire to pay, is the instalment system. A special letter should be sent in reply to such people, couched in a friendly tone, stating that the firm is willing to meet them as far as is possible, and suggesting that the account be paid gradually by instalments. It should be mentioned, also, that these payments should be made each month, commencing on such-and-such a date, and that the firm is content to leave the amount of the instalment to the debtor. Then, if by the date appointed, neither payment nor a letter of explanation is forthcoming, it may safely be assumed that the excuse of poverty is not genuine, or, at least, that the debtor is not honestly enthusiastic regarding the liquidation of his debt. When a person is unable to pay his debts it is not, as a rule, because he has no money at all, but merely because he has not sufficient money wherewith to meet all his debts at once. Consequently, if such a person be honestly anxious to meet his liabilities, a small monthly sum—even a shilling—would not be beyond possibility. It may be considered better, in many cases, to specify an actual sum, rather than leave it to the choice of the debtor. But, in either circumstance this test of good faith applies.

If, however, none of these remaining five debtors has sent any form of reply to the last letter, we must prepare for them

a second epistle against the next rendering. Again we find these accounts grouped together in the card ledger, while those in the February alphabet will now be ready for the first letter. This second letter is the central pillar of the debt-collecting construction. Any letter sent previous to this is only a gentle reminder, and any letter sent subsequent to it must deal obviously with the necessity for more drastic steps. The first reminds; the last threatens; but the middle letter is the letter which reasons.

Those people who are short of ready money, and who do not lend themselves to the instalment plan, intend presumably to pay off their debts one at a time, as they find it possible. It is our object, therefore, to be one of the first of those creditors who thus receive payment, partly because we desire the money quickly, and partly because the creditor whose account is left to the last may never be paid at all. There is therefore no stronger appeal which can be made at this juncture than that aimed at the debtor's sense of fairplay. A friendly letter, but gently firm withal, pointing out the unfairness involved should the debt remain any longer unpaid, strikes a note which no person of decency can resist, and, what is important, without in any manner antagonising the recipient. It should be written in the following strain:—

"Dear Madam,—You will see by the date of the enclosed account that it is now considerably overdue. We think you will agree with us that the length of credit which you have received is a very fair one, and that we are now justified in requesting a settlement.

"We are particularly anxious to avoid those unpleasant relationships which are apt to arise between firms and their clients over such matters; and we are anxious to maintain the mutual confidence which at present exists between us.

"We therefore prefer to approach you frankly in this manner, knowing that you will appreciate the reasonableness of our request, and give it your immediate attention.

"Yours faithfully."

Here, again we have the sharp, bald reminder in the first sentence, softened by an appeal to reason in the second. The third sentence mentions the possibility of unpleasant relations, but gently points out that these will not arise unless through the persistence of the debtor. The letter concludes with an appeal to fairness and friendliness which cannot be ignored by any self-respecting person.

Let us suppose that, out of the five remaining accounts, the sending of this second letter results in three payments. There now remain two accounts to be dealt with; and these will still be found lying in their alphabet—the last two cards of January. Those remaining in the February alphabet will now receive the second letter; while those of March will be due for the first.

These two belated debtors are either in very desperate financial straits indeed, or are persons of the "hopeless" class. Before passing them on to the care of the solicitor, there is one more chance of enticing them to part with what ready money they possess toward settlement of the account, and of showing at the same time that the firm is still open to receive explanation, and willing to come to any arrangement which might meet the situation of the debtor. On the following month, therefore, he third and last letter is sent. It should run thus:—

"Dear Madam,—We are sorry that we have had no reply to our last letter regarding the enclosed account, and that this matter has not been settled under circumstances which, to us, would be much more preferable. We should still be glad to hear from you regarding this account, stating the date by which you would be willing to make payment, or explaining the cause of the delay.

"We shall be glad to hear from you within ten days' time, as, after that date, this account falls to be collected by our solicitors.

"Yours faithfully,"

In this final letter the sting is in the tail. It is the last word; and that word must be adhered to. If no reply be received by the allotted time, straight to the solicitor's office that account must go, no matter whether the debtor be peeress or peasant. This series of letters should never be embarked upon if the creditor has not the courage to pursue the matter, if necessary, to the bitter end. To threaten, and then to delay action, is the worst of follies. The photographer, after having dealt thus generously and frankly with his customer, can do no more. Courtesy has done her utmost, and justice must now be claimed. He is safe in the knowledge that any customer who will run the gauntlet of these appeals, and remain heedless, is not a person with whom it can pay him to deal, and the lawyer may do his worst.

It is this class of debtor who occasions the humour of account-collecting, and thus to some extent mitigates the trouble and expense which he creates. A business man told me not long ago of a lady who had made a number of purchases from his firm, but who afterwards showed little intention of settling her lawful debts. He had written her on several occasions, and had continued to render the account over a period of two years. At last, obtaining no response, he wrote to the lady's husband. That gentleman, a military dignitary, replied by return of post enclosing a cheque for the sum due, saying that he would never deal with that firm again, and requesting them to erase his name from their books! It does not occur to such people that there exist persons in the world with whom any firm would prefer not to deal.

A similar case is that of a lady who had owed our own firm a small account for some two or three years. We had learned from outside sources that, like the devil, she went about the world seeking what she might devour, and paying nothing for it. Consequently, after a certain time, we were obliged to score the debt off our books. One day, however, she calmly entered our reception room and left with us a photograph, which she ordered to be copied. The receptionist did not recognise her until after she had gone, and we therefore drafted a polite letter to the lady pointing out that we had not, as yet, received payment of the enclosed previous account, and mentioning that we thought it only fair that this should be settled before her new order was proceeded with. This brought no reply; and, lest she should again escape us, our solicitor sent her a note threatening legal proceedings. By return we received a cheque, accompanied by a communication which stated that the fair writer had received a most insulting letter, and instructing us to return the photograph which she had left, as she had no wish to have any further dealings with us.

It will be observed that replies from persons who are thus cornered consist of two remarks:—(1) That the recipients have been outrageously insulted. (2) That they intend to have no further dealings with the firm in question. These are, after all, the only jibes left to them, as the only resort of the handcuffed malefactor is to spit upon his captors.

In my own firm, where this system of letters is employed, it is found that, of all the debtors—and there are not many—who reach the stage requiring pressure, about one-half respond to the first appeal. One quarter reach the second letter; and those who ultimately require the attentions of the solicitor are practically negligible. This is a very marked contrast to our experience previous to the introduction of the system; and the net result is, that, while reducing the risk of offending customers to a minimum, the total of our outstanding accounts, in proportion to the turnover, has been exactly halved. This means that the other half is always in the bank, instead of in the pockets of the public; and, in days such as these, few photographers can afford to despise so convenient a source of floating capital.

In addition to these three letters, another and separate appeal may be drafted to deal only with accounts of small sums, such as a few shillings. These should be settled much earlier than the larger debts, as the clerical labour and postage occa-

sioned by their collection is so much greater in proportion to the sum involved. It is these small accounts which people will overlook and forget, and such a letter, pointing out the high cost of clerical work and postage, can easily be drawn up, asking the recipient's co-operation in this matter. This, also, has been found successful.

It is, of course, unnecessary that any of these letters be written out laboriously on each occasion. A few dozen of each should be printed on duplicating machines by firms who do such work, omitting the words "Dear Sir" or "Dear Madam." These, along with the customer's name and the date, are typed in when required, and the letter signed. It has then all the appearance of a personal letter, but involving only a few seconds to write.

It is not suggested that the exact letters reproduced here should be used; in fact, the more personal the form the better, and each photographer must modify the phraseology to suit his particular class or type of client. The main rules which must be adhered to are that of patience and courtesy. The slightest deviation from these merely defeats the creditor's object, which is to collect his money without loss of goodwill. I once saw a collection-letter of a large drapery and furnishing store. It commenced thus:—

"Dear Madam,—We wish to point out that the time elapsing between the receipt and the payment of goods cannot be extended indefinitely . . ." and the letter proceeded to point out the heavy expenses which the firm was obliged to meet each month.

Now, this opening sentence is merely rude. It is not even cleverly rude. The only feeling which such a remark could excite is that of anger, and anger is the last psychological state in which a man or woman will be tempted to part with money. The subsequent whine about heavy expenses is equally useless. What have such matters of finance to do with an outsider? These things are surely the concern of the manager and the directorate, and mention of them serves merely to suggest that the firm is in financial difficulties. The recipient of the letter, after having been annoyed by the opening remark, will rather feel inclined to rejoice at this fact. I give this example merely to show how a foolish collection letter may easily be written when the author is in the wrong frame of mind. The writer of this letter was evidently annoyed at the stubbornness of a number of debtors at a time when heavy expenses were looming. Undoubtedly his anger was justified; but it was not the most happy moment at which to draw up a form letter. The opening sarcasm, followed by the talk of expenses, shows clearly that the letter was thus hastily composed in an hour of ill-humour.

Sarcasm is a delightful weapon, and for the purpose of pointing out the follies of mankind it is unrivalled. But it should never be used personally, particularly in a letter, and, more particularly still, in a business letter. For satire or sarcasm is useless against the person satirised. Either he does not see it, or he is merely embittered. It is the rest of mankind who perform the reforming function. They hear or read the satirical remark, and are amused. It is not directed against themselves, and it serves to illuminate the object satirised much more clearly than their own minds have hitherto been able to conceive it. They begin to realise the folly of the custom, and the persons responsible are ultimately laughed out of countenance. Satire, therefore, however brilliant, requires an audience; and a letter is seen only by the recipient.

It is not now the fashion to steal, nor is it held polite to bear false witness against one's neighbour; but tardiness in the payment of accounts is practised by the very best people, and is not, in consequence, a sin. If, however, the weathercock of custom were swung to-morrow, and unpunctuality in payment became a breach of etiquette, few would be found to possess the courage to ask credit, and debt would be confined to cheap suburbs and the slums. But what person of influence will first dare to proclaim it "bad form"?

PELHAM SWINTON.

THE PHOTOGRAPHY OF CHILDREN.

[A notable feature of the recent Blackpool congress of the Lancashire Society of Master Photographers was the paper read by Miss Flemming, F.R.P.S., of the Freckleton Studio, Nottingham, which, by the kindness of the author, we are able to print. The paper was illustrated by a number of lantern photographs, the description of which in the text well emphasises the many interesting suggestions and hints which are given by Miss Flemming from her wide and specialist experience in the portraiture of children.]

We each have our ideas and ways of working, and it is a good thing, too, otherwise the photographers' windows would lose half their attraction, and there would be no individuality. But surely it is good for everyone to try to interchange ideas, both from the friendly and the business point of view.

Photographing the children is one of the most interesting branches of photography; but by no means the easiest. As you all well know, it is not merely knowing how to manipulate one's camera, and what exposure to give; it is getting the little folk to look natural and happy, and they won't give you *that* expression unless they are absolutely at home with you, and real friends. Still it is not usually a difficult matter to get friendly with them, only it takes longer with some than with others.

The shy, sensitive child is the kind one has to be very careful with, and it is a mistake to try to be very friendly with them in a hurry. At Mr. Freckleton's studio in Nottingham, we have a very comfortable room adjoining the studio, which is used mostly for getting the children ready in. It is considerably larger than the ladies' dressing room; there is plenty of room for the children to play about, and also for the mother or nurse to get them ready.

We have a private telephone through from the studio to the reception room, and if some children are coming in to sit, the receptionist usually rings through and lets me know. She usually waits until they are out of the reception room and on their way upstairs before ringing through, and then she will often give me an idea of the kind of child that is coming up. Perhaps it will be "Mrs. Smith is getting her little girl ready in the children's room; she says she is dreadfully shy with strangers, and is afraid you will not be able to take her." My receptionist is, I know, smiling to herself, as the idea of our not being able to get a picture of the little one rather amuses her!

I give Mrs. Smith and her little maid a few minutes to settle down before going to see them, and when I do go I take not the slightest notice of the child, but start talking quietly to the mother, letting her know that it will not be a

difficult matter to make a picture of somebody, if she will be good enough to leave it to me and not worry the little one in any way. Then I go back to the studio, and, knowing the kind of photograph required, get the background ready, camera focussed on a few toys put ready on the floor, or on a small table, plate, etc. Mrs. Smith is then asked if she will bring the little one in and let her sit or stand near the toys. Before the child has reached the studio I vanish into another room, and stay there until the kiddie is used to her surroundings and evidently interested in the fresh playthings. Then is one's chance to come quietly in (taking no notice whatever of the little one) and slip behind the camera, which probably may require focussing again.

Underneath the camera we have a musical box fixed so that it is not seen, and when I think the little one is in a good position I just press the spring which sets the music going. The child is usually so astonished that it forgets all about its shyness, and you have plenty of time for an exposure.

But the expression is apt to be one of surprise, and we want a more confident look.

Generally by the time you have made one exposure the child is feeling more used to its surroundings, and you can venture to show yourself a little. But even then I usually find that with a very shy child it is best to keep away from it. If it shows signs of getting tired, we try to find a fresh toy, and give it to the mother to hand to the little one. Very often a simple little thing like a flower will draw a smile from even a tiny child when toys have failed.

Such a shy, little maid of four or five years was brought up to me one day, and I tried her after a little while with various toys, but she looked at me with big, serious eyes, and not the ghost of a smile could I conjure up. There was a big bowl of large yellow daisies in the studio, so lifting them out of the water, I scattered them all round her on the floor where she was sitting, letting two or three of them fall in her little lap. You should have seen the smile dawn on her little face. There was no further trouble with her expression after that.

Some little folk are dreadfully matter-of-fact and grown up, even at four or five years old and younger. You have to be very careful as to how one tries to entertain these precocious little beings, or you may suddenly be made to feel *very* small. Some years ago Mr. Freckleton had a wee mite of perhaps two or three years to photograph, and it was one of those rather stolid children who seem to have no expression or animation in their faces. He was playing bo-peeps to it behind the camera cloth and cutting funny capers generally, anything to rouse some sort of expression into the youngster's face, when all at once the child turned round to its mother, and exclaimed, "Oh, mother, what a funny man!" Well, that broke the ice; everybody laughed; it sounded so grown-up from such baby lips.

But, as you all know, some children are much easier than others to photograph; some are bright and full of confidence, others are just as dull and apathetic. Then, hardest of all, there is the spoilt child who is usually brought in by a fond mother, and two or three equally fond aunties. They immediately start to tell you that he is *the most wonderful* child that ever it was your privilege to photograph; you are thinking to yourself that you would not very much mind forgoing that privilege. If possible, only the mother, or perhaps the nurse, should be allowed to stay in the studio, and, as a rule, I find it easier to get a picture of a spoilt kiddie, if *no* toys are shown to it, and as little notice taken of it as possible. Also, it is best to be as quick as possible with this kind of youngster, and not attempt to play with it; just to attract its attention by a touch of the musical box will often do the trick.

A very difficult child to deal with came to the studio the other day. The youngster was naturally very shy and nervous with strange people, and was unfortunately spoilt into the bargain. It was no sooner brought up into the children's room than it started to scream as hard as it could. The mother was promising it chocolates and a good whipping alternately, and I could see there was small chance of a picture that morning. It had been told all the way coming that it must be good, as it was going to have its photograph taken, but the only idea that the youngster's little brain retained was that "it was going to be taken." Where, it did not know, but the poor little beggar was really frightened, as well it might be. Advising the parents to come another day, I also suggested they should not say anything further to the child about being "taken," but let him forget all about it if possible. If they would bring him in again in a week at the same time of day, and have him brought in at the other entrance to the studio (there are two ways into that room), I would have everything in readiness, and we hoped that by coming in another way he might forget his previous fears and give us a chance of getting him unawares.

They did so, and, coming into the room from an entirely fresh end, and also seeing no one about and a new toy lying on the floor, the child was not so nervous, and by the time five minutes or so had elapsed I ventured to show myself at a distance and slip behind the camera. By and by I got a couple of exposures, one of which was fairly good. Only a small order was the result at that time, but the parents remembered that the child had been treated tactfully and kindly, and they brought it in again next year. The child was older, gave far less trouble; and a good picture, followed by a good order, was the result.

I am only telling you this to show that it pays in the long run to have patience. Your customers do not forget it, and they tell other people, too. I find it a good thing to notice the kind of toy children like, and, as far as possible, let them have their choice, even if you may not think it quite suitable. One little lad would have nothing else but a skipping rope, rather a girlish toy, but it met with his approval. Others, again, are very anxious you should photograph their own dolls, and it is not wise to refuse, even if the teddy bear or the doll is nearly double the size of the kiddie. I take one negative to please the child, and then another that I think will suit the mother. You gain the child's approbation, and that is half the battle.

Sometimes it is a great help, if toys fail, to let the children play about and pretend to take a photograph themselves. They get so interested, and it is such fun to them, that it is an easy matter to get a good expression of them when you subsequently take a negative. It all takes time, but I find it is well worth while.

By the way, a cat is always useful in the studio, as most children are fond of animals. We have had one for fourteen years, and he is very good indeed at sitting with the little folk.

If you are, however, fortunate enough to posses both an intelligent dog and a cat that are on friendly terms with each other all the better; you can use them both when needed.

Of course, you may not be able to find a dog as well trained and devout as one of Mr. Freckleton's, but I find most terriers are very teachable, and patient, too.

I will next show a slide which may perhaps give you an idea of how you can get a homely-looking little picture, by making use of both the cat and a bit of sunshine on the floor. It was morning in summer time, and the cat had found the warm patch of sunlight. So putting the child into a comfortable little chair near the cat, I gave it a book of coloured pictures to look at. The rest was quite easy. Talking of sunshine, the little bit that comes in through the side-window at one end of the studio for an hour or two in the mornings is most useful for making a change in one's style of picture during the summer months.

Our studio is practically divided into two rooms by means of curtains drawn right across the middle; these can, of course, be thrown right back when we have a large group to take. One end has a top light and also half-watt lamps fitted high up in various parts of the ceiling, so that we can take our sitters in any part of the room. The other end is lit only by a large side window, and it is through that window in the morning that the useful little ray of sunshine comes.

Another of my slides shows a different effect, because the kiddie is standing very nearly with her back to the window, and the little face is lit chiefly by reflected light. To make the picture look as sunshiny and spring-like as possible, I turned the background slightly at an angle towards the window, so that it was lit up almost as much as the child, and on the side of the ground where the little hands are I pinned a few long sprays of blackthorn. Terribly prickly stuff it is, too, but just the thing for a spring picture. I removed the longest of the thorns before letting the child's little hands come near.

Here I show you two youngsters playing at school with the dog to assist. I am afraid the dog did not see so much fun in it as the kiddies; all he saw was a piece of dog biscuit waiting for him on top of the camera. Of course, it is not a good likeness of the two children, dressed up as they are, but before they leave the studio we always get two or three negatives in their ordinary dress, showing more of the little ones' faces. These "play pictures," as we call them, are really a good investment. They are a bit out of the common, and even though the parents do not select them for their order, they generally like to have one copy to keep for themselves, and that is usually shown to their friends. The friends in question admire it, and think they would like to take their little ones to a studio where the children are allowed to play and have a good time. Then, again, an enlargement from one of these "play-pictures," hung up for a short time in the show-room, is always an attraction and interests the customer.

Last summer I had a wedding party to photograph in their own garden. When the bride and bridegroom had been taken and were on their way to the station, I got the four little bridesmaids to come with me into the next garden, where there was a small fountain. I arranged them round this, turned the water on slightly, and let fly with two or three plates. The kiddies thought it great fun, because they could run about the grass without their shoes and stockings and play with the water. What their mothers said when they saw the wet frocks I did not wait to hear!! This picture was put in the show-case with the wedding groups, and, being something a bit out of the ordinary, made people talk.

I spoke a little while ago about the usefulness of flowers in a picture. Now and again one gets a rather plain child to photograph, and then a few flowers come in handy, either out of doors or in the studio.

Flowers are often useful in the studio. Here is a child sitting on a fairly large table, and two big bowls of flowers and grasses are standing on the same table. One is slightly at the back of her; the other one she is holding in her lap. The two vases are of such a height that they do not show in the picture, only the tops of the flowers, and just one or two long sprays of grass which break the line of flowers, and, at the same time, merge softly into the background. Out of doors is easier, especially if there are some of those tall daisies anywhere about. Let the child gather a few, and it will forget to a great extent that you are going to photograph it; you will then get a more natural expression.

In making a picture of a young mother and baby, I find a simple wicker crib very useful. The crib rests on its own wicker stand and is about 3 ft. from the floor, so that the mother can sit comfortably on a chair and lean over her baby.

In making fire-light pictures of a little girl I find it best to tell her to hold her hands out to the fire and see how warm it is, or to swing her dollies to sleep in the warm glow, and even though the fire is only electric, the child usually enters into the fun of it, and does as requested.

For pretty fire-light studies, however, I prefer an older child. Children seem to me to call for sunshine more than fire-light. The next three slides do not exactly deal with "Methods of Child Photography," but they may perhaps interest you as ordinary home work in the winter evenings.

The first was taken in Mr. Freckleton's dining room just after supper, while the white cloth was still on the table. The only illumination was five ordinary incandescent gas burners lit under orange-coloured shades. Roughly speaking, the exposure would be about four or five seconds. Those are red apples in the fruit dish, and that is an orange that Mr. Freckleton's daughter is peeling. This picture and the two following are all taken on Marion's Iso Record plates.

The family gathering round the fire was taken at 9 o'clock in the evening, and the only illuminants were two half-watt lamps, each of a 100-candle power—one up in the centre of the ceiling and the other in the stand lamp you see in the picture. The shade over this lamp was also orange-coloured. Talking of the winter evenings, I will tell you what we do at the studio after Christmas to try and make fresh customers when things are a bit slack. We have what we call a "lantern social" in the evenings, say, about once a fortnight, and throw on to the screen probably a 100 or more chudren's pictures during the hour and a-half that the "social" lasts. Invitations are sent out to several ladies who have already brought their kiddies to sit, and they are asked to bring a friend with them. Suppose you send out about fourteen invitations, and perhaps twelve accept; that means you will have twenty-four guests to attend to. That is really enough, I find, to look after, if you are to give each one a little personal attention, and it pays to do that. We usually start our social at about 7.15. After showing the slides, which generally occupies about an hour and a-quarter, the lights are all turned up again, and cups of nice, hot coffee and a few biscuits are handed round. The customers thoroughly enjoy it, as it is a novelty; it does not take long to get the studio ready and the lantern fixed up. The white backgrouud is always ready to act as a screen, the camera stand is just right to carry the lantern; we fetch a few more cosy chairs up from the reception room, fill a bowl full of fresh flowers, and your social room is ready. My assistants are very good; they take it in turns to stay and help with the coffee, and in making the customers feel at home and comfortable.

A most important thing to remember is *always* to have slides of those children, whose parents are your guests for the evening, ready to put on the screen. It is *those* pictures they look forward so proudly to show to their friends. We generally invite the ladies only, thinking that it is perhaps rather a tame entertainment for the gentlemen, especially as there is only coffee at the end of it, but several times the fathers of the kiddies have come and have quite enjoyed it. One special evening we invited the children as well as the parents, and, as the Americans would say, it was "some night." It was rare fun to hear some of those youngsters' remarks. But it did a lot of good, from the business point of view, because the children talked a lot about it afterwards to their little friends. If only we can give the people something new and good to talk about, we ought not to have many slack weeks. The secrets of success are, I venture to think, to keep up to date, always try to find something new and attractive; above all, see that one's work is good and turned out promptly.

FANNIE FLEMMING, F.R.P.S.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[Regularly each year the Society of Chemical Industry renders a valuable service to those connected with the manufacturing and scientific sides of photography by including in its "Annual Reports" one on photographic materials and processes. The report for the year 1921 is written by Mr. F. F. Renwick, F.I.C., whose large share in photographic research qualifies him exceptionally as a recorder of recent investigations in the technical improvement of processes of making negatives and positive prints, orthochromatics and colour photography, cinematography, and photo-mechanical processes. The report exhibits the work which obtained publication last year in its relation to previous knowledge better than any other communication which comes before the photographic industry, for which reason we endeavour to find a place for it in our pages. As regards the references to original sources of publication, it should be explained that the contraction "J" denotes the fortnightly "Journal" of the Society of Chemical Industry, in which are published abstracts of the chief papers dealing with the chemical side of practical, scientific, or industrial photography.]

The first steps towards the achievement of photography as a practical art were largely due to men of acknowledged scientific repute of British birth. The names of Tom Wedgwood, Sir John Herschel, Sir Humphrey Davy, Henry Fox Talbot, and Robert Hunt readily occur to the mind as distinguished men of science who devoted considerable attention to the subject in the first half of last century. Herschel, Fox Talbot, and Hunt all added considerably to the list of known photochemical reactions, and to Fox Talbot belongs the distinction of working out more than one process to a successful issue and of introducing the method of producing positive prints from a negative and so enabling the production of any number of copies. It is highly fitting therefore that the Royal Photographic Society should recently have undertaken the guardianship of Fox Talbot's apparatus and results and the setting up of a permanent memorial to him.

Towards the end of last century, after the establishment of numerous firms for the wholesale manufacture of sensitive materials, very few men of note in the scientific world devoted themselves to the study of photochemical problems in spite of their profound importance and interest, but the death, at the close of last year, of Sir Wm. de W. Abney removed from our midst one whose name will always be associated with his valuable contributions to photographic science which traversed a very wide field both in the chemical and the physical aspects of the subject.[1]

The present flourishing photographic industry owes its development almost entirely to the dogged energy and perseverance of a number of untrained enthusiasts whose names are mostly unknown to scientific men, and it is probable that in the whole world there were not a score of well-trained chemists employed in it thirty years ago.

The present outlook is very different. In the first place the industry has absorbed and trained a considerable number of young men who had first received an education in scientific method and who have elaborated Hurter and Driffield's invaluable system of examining and classifying photosensitive materials, so that to-day quantitative modes of expression are, or should be, regularly employed by all serious workers to describe their attributes.

Secondly, the industry has become so huge and complex that it would be impossible to produce the required quantities and the variety of these very delicately balanced products with reasonable uniformity without an elaborate system of scientific control. (In illustration of the magnitude of the industry the following figures are instructive. Approximate number of cinema theatres in existence 90,000; estimated length of cinema film exhibited every week 300,000 miles, of which at least 10,000 miles represents entirely new matter, no allowance being made for the enormous amounts consumed which are never issued for exhibition. To this must be added all the roll films and plates and the positive printing materials of all kinds used in other photographic work, both professional and amateur.)

Thirdly, as a consequence perhaps of the industrial difficulties which have arisen since the war, there is a keener appreciation of the overwhelming importance of light as the prime cause of those innumerable natural synthetic and analytic reactions on which all living matter depends for its growth and development, and as a result we observe a great revival of interest in the mechanism of photochemical changes and a desire to direct and control them for the service of mankind. It has become evident that efficient photochemical manufacturing processes would save the community the expenditure of much manual labour and postpone the depletion of our rapidly dwindling and irreplaceable supplies of coal and oil. Moreover, if such processes can be colour-sensitised effectively there seems less reason to assume they would require to be carried on in tropical climates to be economically successful.

Photography then, should be regarded as merely the first photochemical industry to be established, and as such it cannot fail to benefit from the researches in other branches of photochemistry, the study of catalytic reactions, and particularly from investigation of heterogeneous reactions in colloidal media which appear in the future.

As evidence that British photographic chemists are alive to the importance of widening their outlook, the appearance of a new journal published by the Scientific and Technical Group of the Royal Photographic Society under the title "Photographic Abstracts" is a most welcome sign and deserves the support of all serious workers in the subject. The enlightened policy of those firms who jointly bear the greater part of the cost of this publication is highly praiseworthy and cannot fail to be rewarded through the greater zeal for and efficiency in the performance of their duties which it will surely evoke among their technical staffs.

Photography has undoubtedly regained much of its popularity as a pastime, and the lure of the cinema theatre seems irresistible to the majority; moreover, the employment of photo-mechanical processes for illustration work continues to grow steadily, while professional and scientific photography continue rapidly to multiply their already numerous ramifications, so that if a reasonably early return to normal trading conditions should occur it is safe to predict a considerable permanent expansion of the industry. There is a far wider and more intelligent appreciation of the advantages of colour-sensitive negative-making materials for all kinds of work than before the war, probably as a consequence of the large numbers of men who learned from experience on active service how indispensable such plates were to our success. There are indications of a desire on the part of manufacturers to simplify their problems by producing only a few articles in large quantities, but it has long since been found impossible to produce even one product which suits all tastes, so many and so subtle are the requirements of different users.

While the importance of photography in everyday life is but dimly realised by the general public, few even among the highly-educated classes realise what an effect it has had on man's intellectual life during the past two years. But for the fact that a few star images occupied certain positions on a few photographic plates exposed at the solar eclipse in 1919, it is certain that the majority of us would have taken no interest in theories of relativity. An attempt to verify these observations on Christmas Island in the Indian Ocean and elsewhere at the eclipse next September is already organised and will again rely on photographic records of apparent star positions, when doubtless there will follow another flood of ideas on this abstruse subject. In delicate work of this character careful attention must be paid to various disturbing factors, such as the mutual influence of adjacent images—a subject recently re-studied by F. E. Ross.[2]

During the past year the photographic industry has suffered from the prevailing world-wide trade depression, though perhaps less acutely than most. There was a marked fall in the prices of fine chemicals during the summer months, but this advantage may be lost, presumably to the benefit of the fine chemicals trade of this country, by the operation of the Safeguarding of Industries

1. Sir W. Abney, *Phot. J.*, 1921, *61*, 44, 296.

2. F. E. Ross, *Astrophys. J.*, 1921, *53*, 349.

Act, 1921, which came into force on October 1 last, since every fine chemical and almost all the apparatus used in the industry fall within its scope.

At the date of writing, the depreciated value of the German mark apparently outweighs any encouragement which the Act might have given to our fine chemicals industry, while this measure certainly makes the obtaining of rare synthetic chemicals from abroad an extremely aggravating process.

Raw Materials.

Among the raw materials of the photographic industry, the three which call for the greatest care, judgment, and experience in their selection and use are gelatine paper and collodion cotton. There are no generally recognised methods of testing any of these products for photographic purposes except the obvious one of trying them on a small scale and noting the results before proceeding to large-scale use, and it must be admitted that at present there seems little prospect of devising really reliable chemical methods of testing them.

It is satisfactory to be able to record that considerable progress has been made in this country and elsewhere during and since the war in the production of first-class gelatines suitable for all photographic purposes, and we are now quite independent of Germany in this matter.

Regarding paper stock suitable for bearing sensitive emulsions, some progress has also been made, but of a more limited character. Supplies of collodion cotton of British manufacture suitable for preparing print-out collodion emulsions are also more easily obtainable than in pre-war days.

While a great deal of new work on gelatine has been published during the past year, a proper appreciation of the bearing of modern research in this field of photographic problems is as yet impossible. It becomes daily clearer, however, that there are numerous facts, with which most photographic works chemists are familiar in practice, whose interpretation is rendered easier by the aid of the newer theories dealing with colloidal forms of matter, and it is to be hoped that the photographic industry will derive some benefit by the adoption of the methods of examining gelatine which are gradually being worked out.[3] In many cases, however, these are little more than slight modifications of old physical tests which have been long since found to be of no great assistance to the emulsion maker.

What is urgently needed as a beginning is a satisfactory method of determining the relative proportions and characteristics of the hydrolysed and anhydrolysed constituents of commercial gelatines. A ready means of separating them unchanged would enable their separate influences on emulsion-making processes to be properly studied and the diverse photographic qualities of different brands of gelatine to be correlated with their chemical as well as their purely physical differences. Moeller's recent studies[4] of Procter's discovery that the addition of a little acid precipitates dissolved gelatine from saturated solutions of common salt leaving the degradation products in solution, appears to offer an opening for attacking this problem.

Several new patents for flexible supports of a non-inflammable character have been granted,[5] but from one cause or another the proportion of positive film of the "non-flam" type shown in picture theatres is still quite small, hence it would seem that the ideal support is still to seek.

Storage of Sensitive Materials.

One of the most intricate problems constantly confronting the manufacturer of light-sensitive materials is the preservation of their properties unimpaired up to the time of use—a period which may amount to several years, under the most varied climatic and other conditions of storage. The problem presents two essentially different aspects; firstly, the exclusion, by the use of more or less impermeable wrappings, such as sealed tins, foils, waxed papers, etc., of moisture and injurious gases or vapours, and secondly, the discovery of stabilising agents or of improved processes of manufacture which will arrest or minimise any tendency to spontaneous changes in the sensitive materials themselves. Naturally enough, discoveries falling within the second category are not usually published but become jealously guarded trade secrets, so that the chemistry of stabilisers is an almost unexplored field of scientific inquiry.

A novel mode of protecting a photographic film against moisture has been patented by F. W. Lovejoy,[6] who applies to the surface a transparent layer of a fatty acid (palmitic or stearic) which is saponified and dissolved by the alkali of the developer. E. Merck and L. Weber[7] claim the addition of certain salts, e.g., ammonium oxalate or acid phosphate, to the sensitising ferric oxalate preparation for improving the keeping quality of negative tracing (blue print) papers. A report by the Eastman Kodak Company[8] deals with the fading of finished prints made by the same process and recommends that instead of plain water, a 0.2 per cent. potassium ferri-cyanide solution be used for development. It condemns the practice of adding hydrogen peroxide to the development water as conducive to rapid fading.

Before proceeding to deal with the more usual chemical and photochemical side of photography two very ingenious inventions must be mentioned.

The first is Louis Lumière's method[9] of producing a composite photograph giving a very satisfying illusion of solidity (photo-stereosynthesis). He prepares a number of positive transparencies of glass, each of which depicts sharply a slightly different plane of the object, other planes being thrown out of focus by special optical devices during the making of the original negatives. These transparencies must be properly spaced in due order one behind another, in a framework lighted from the rear and viewed normally to secure the desired effect.

The second is H. M. Edmunds' invention enabling relief models in wood, ivory, etc., to be produced mechanically from a photograph (photosculpture).[10] A spiral pattern is projected optically on to the sitter's head and shoulders and appears on the photograph as a close series of contour lines. A special machine is employed to translate the motion of a stylus along these contour lines into the appropriate motion of a cutting tool on the block of material employed. The results shown in last year's photographic exhibitions are certainly very interesting.

Aviation has led to the development of new and important applications of photography to surveying and map-making from aerial photograpns. The progress already made in this highly technical subject has been ably reviewed by L.-P. Clerc.[11]

Cinematography.

Cinematography has reached such enormous dimensions that it must now be regarded as a separate industry of a highly complex character, which uses huge quantities of sensitised negative and positive film as its chief raw materials, rather than as a branch of photography. Nevertheless, any further improvements in these raw materials must depend on the chemists and emulsion makers in the photographic industry and will naturally find many other fields of application, but such progress is necessarily rather slow. The energies of research workers in cinematography are mainly devoted to the solution of optical and mechanical problems with which this report does not profess to deal.

It is of interest, however, to note that inventors appear to be chiefly engaged on four problems:—

1. The elimination of the disadvantages arising from the intermittent projection and the discontinuous motion of the film through the projector. A large number of devices permitting continuous motion of the train of pictures has been patented[12] and some of them publicly exhibited, so that it may not be long before flicker, underlighting, film breakage, and other evils will be things of the past.

2. The discovery of a satisfactory method of imparting the appearance of stereoscopic relief to motion pictures.[13]

3. The perfection of a simple means of synchronising sound records and motion pictures—a feat which was shown to be possible in skilled hands with separate gramophone and cinema records at the Brussels International Congress of Photography in 1910.

Recently, however, considerable success has attended efforts to combine both the picture and the sound record on one film. Variations in opacity in the photographic sound record cause rapid fluctuations in the intensity of an electric current passing through some form of light-sensitive cell, and these operate suitable amplifying telephonic devices for reproducing the original sounds.[14]

4. The production of satisfactory motion pictures in natural colours.[15]

In regard to this long-sought goal it appears fairly certain that for some time to come a two-colour system, in spite of its serious limitations, is more likely to be a commercial success than a three-colour method, since the latter inevitably offers far greater technical difficulties. Modern developments indicate that a practical solution is likely to be found first either in a method by which each unit picture on the film is a composite record in colour which can be used in existing projectors without alteration, or by one of the optical methods enabling the simultaneous making of the two records on adjacent areas of one film through a single lens and projection through two adjacent colour filters to combine on the screen.

F. F. Renwick, A.C.G.I., F.I.C.

(To be continued.)

GERMAN SCIENTIFIC INSTRUMENTS.

The Board of Trade Inquiry Committee.

The Board of Trade Committee, which has been charged with an inquiry into the question of German optical and photographic goods, with a view to the possible necessity of imposing an additional duty, resumed its sitting on May 31. The first part of the proceedings, in which the case for the applicants was stated, was reported in our column of May 19. Sir Henry Rew, the Chairman, stated that the case for the applicants had now been closed, and the shorthand notes of the evidence were available; he therefore called upon the counsel for the parties resisting the application, Mr. T. W. H. Inskip, K.C., M.P.

Mr. Inskip said that he had to present to the Committee the substance of the case to be put forward by seven firms, two of them interested in the supply of German photographic instruments, and the others in more purely optical manufacture. He excluded the question of drawing instruments, which was of almost insignificant proportions. The broad case which he presented with regard to the other articles which formed the substance of the inquiry was that the facts were not as had been alleged on the other side. Some of his own witnesses were sole agents for firms which manufactured in Germany, and they contended that while the very cheap articles which had formed the subject of the complaint had not come into the country by backdoor methods in the sense of smuggling, they did represent, nevertheless, a class of articles whose sale outside the ordinary channels of agency was really illegitimate, though he did not use the word in any opprobrious sense. He maintained strongly that the articles of German manufacture which came into this country through the regular channels of duly appointed agents were well comparable in price with similar British articles. He dismissed the plea, which was implicit in some of the evidence already tendered, that the industries concerned deserved some special treatment, either because they were important, or because during the war special efforts were made to establish them in this country. He did not think that that was the basis of the applicants' case. A suggestion which was far more strongly pressed was that this importation from Germany led directly to a diminution in labour and output in this country, but he thought it was overlooked that there was a very great depression in trade generally. What surprised him most about the evidence already tendered was that so little had been said about depreciated exchange. The ability of the German to undersell the English competitor arose from the fact that the internal value of the mark was very different from its external value. If it were not for that difference between internal and external value, the mere depreciation of the mark would not place the Germans in an advantageous position for competition. With the approximation of the internal to the external value of the mark, which might be anticipated, this underselling would tend to disappear. He noticed that witnesses on the other side had been rather shy of suggesting that employment would be increased if an extra duty were imposed; the most that could be hoped for was that competitors would be handicapped.

After dealing with the case of prism binoculars and microscopes, which, he said, broadly speaking, were not sold at prices below comparable English makes, he said that he would call Professor Bone, of the Imperial College of Science, who would give evidence that for scientific research the best instruments, German or British, must be provided, regardless of price, so that the effect of putting on an additional duty on foreign importations would simply have the effect of causing extra expenditure to scientific institutions, and would not make for protection, because the goods must be obtained whatever price was put upon them. With regard to photographic lenses and cameras, he had two witnesses on this point. One of them, Mr. Robert E. Peeling, was the distributing agent in this country for the manufactures of the Goerz firm, and for certain others; the other was Mr. R. F. Hunter, distributor of the Contessa and Nettel cameras and other apparatus. Both of them contended that while there was a certain amount of importation of German instruments by irregular methods, this was in the face of the efforts which they themselves were making against it, and which they would be in a position presently to make more effectual. It was not the regular German trade which the British manufacturer had reason to fear, but the casual efforts which adventurers were making in this field. A point to be remembered in connection with the complaint of the British houses was that they had been very much overstocked, and that until the stocks in the hands of the dealers could be released there must naturally be lessened manufacture, irrespective entirely of German importations. Then, again, there was significant evidence that plate cameras were going out of fashion; except in certain sections of the photographic industry, where the plate camera was still used, for reasons with which he was not acquainted, the roll film camera had ousted it, and some makers of British cameras had had to reorganise their business. These manufacturers were at present in a transition stage, some of them with very large stocks of the older patterns, which they must liquidate before they could get into full manufacturing order. But it was not to enable manufacturers to do this that the duty was conditionally imposed by Parliament. He read some figures from a reply to a question in the House of Commons by the President of the Board of Trade, that 324,998 cameras were imported from all countries in 1921, of which number 13,233 were sent from Germany. It was not the German competition really which affected this camera question. The popular camera, or the one which had made the greatest impression on the mind of the public, was the Kodak production, which really fixed the rates charged for cameras in this country. Even supposing that the 13,000 German cameras were eliminated, when one remembered the vast extent of the Kodak sales it was difficult to think that the price of the British camera could be raised to any figure which could increase employment to the extent desired by the applicants. It had been stated that the agents for certain German houses gave extremely large discounts. This was quite wrong, as he could call evidence to prove. The suggestion that the Contessa and Nettel cameras represented a new industry in Germany was also mistaken. The products of the houses concerned had been familiar for a long time; all that had taken place was an amalgamation between the two firms concerned. He also referred to the very great variety of models of cameras on sale, and maintained that while great disparities in price might be shown as between camera and camera, if parallel German and British models were selected for comparison the disparity would appear very small indeed.

Mr. J. W. Atha, of J. W. Atha & Co., distributors of the products of Carl Zeiss, spoke mainly as to prism binoculars. As to

photographic lenses he maintained that the prices of the German makes were comparable with those of the British. With the exception of the lenses of Ross, all British makes of lenses were rather lower in price than the products with which he was concerned. Before the war it was on record that Zeiss supplied lenses in large numbers to British camera makers; since the war and up to the present time, British camera makers did not list—and had agreed among themselves not to list—Zeiss, Goerz, or any other German lenses.

The Chairman: Is the Zeiss firm not sending any photographic lenses to this country?

Mr. Atha: Certainly, sir, through us.

The Chairman: To what extent?

Mr. Atha: Practically infinitesimal for British consumption in comparison with what it was before the war.

The Chairman: What is the actual extent of the trade now?

Mr. Atha: Almost negligible. Before the war our principal customers were the large camera manufacturers. These manufacturers since the war have bought not a single lens from us. What lenses have come through are mostly for re-export.

The witness said, in conclusion, that all the German manufacturers arranged their prices in the various countries in the sterling of the country to which the goods were going, that the prices for German goods were invariably higher than English prices, and that during the last six months Messrs. Zeiss had increased their workmen's wages by 100 per cent.

Professor J. W. Bone, of the Imperial College of Science, gave evidence in support of Mr. Inskip's opening statement, that for scientific research the best equipment possible must in any case be provided, so that the effect of adding an increased duty would only be to raise the cost to such institutions, and would not exclude the products.

Mr. R. E. Peeling, agent for Messrs. Goerz, and for F. Deckel, of Munich, photographic shutter manufacturers, and Gustav Heyde, of Dresden, makers of actinometers, said that his firm had been sole agents for Goerz since October, 1920. He gave instances of German cameras which were higher in price than similar articles of British manufacture. Generally speaking, German cameras were not cheaper. In value German cameras represented about 7 per cent. of the whole camera trade in Great Britain at the present time; before the war the proportion was 12 per cent. He believed that Goerz and two other companies represented 80 per cent. of the total German export trade in cameras. He was connected with Goerz before the war, and compared with the turnover of the Goerz agents in this country in 1913 the present turnover was about 22 per cent. In answer to the Chairman, he said that there was a public demand for Goerz cameras. They met a requirement which was not met by British makes. Some of the models were not touched by British manufacturers at all. The greater proportion of the Goerz trade was in roll-film models which British manufacturers did not favour. His firm sold eleven roll-film cameras to every two plate cameras. Certain of the plate cameras had no counterpart in British manufacture. In reply to a further remark by the Chairman, he said that he would not declare the Goerz film cameras to be better than any British make; he was not sufficiently acquainted with all the British makes. So far as Kodaks were concerned the Goerz camera was distinctly better, being lighter and thinner, and more compact than the American model. Asked to what he attributed any stagnation in the photographic industry, he said that he attributed it to four causes. In the first place, over-production in 1920. A number of cameras were produced in 1920 to the order of dealers, and disposed of to dealers, but the dealers in turn had not sold them, and while they were on the dealers' shelves no repeat orders were forthcoming. The second cause was the absence of export trade; the third, the general trade depreciation, and the fourth the fact that British manufacturers were not at present producing popular lines. The amateur photographer wanted something which was no bother to him at all, and the British manufacturer did not seem to be content to meet that need. He added that the loss of export trade was due not only to German but to French and American competition. The witness went on to produce two cameras which he compared. One was the Goerz "Tengor," a roll-film camera only introduced this year, and sold at £3 5s.; the other the Butcher "Carbine," which, he said, was in all respects comparable except that it was heavier, listed at £3. It was the lens in every instance, and to a certain extent the size of the shutter, which determined the price of the camera. He gave particulars of his discounts.

Sir A. Colefax, the counsel for the applicants, produced a Houghton "Ensign," and asked whether it was not comparable with the "Tengor." Mr. Peeling said that the Goerz model he had produced was fitted with an uncorrected spectacle lens, while the other had an anastigmat, and this would account for at least £3 difference in the price.

Mr. R. F. Hunter, agent for the Contessa and Nettel cameras, disputed the allegation that there was any dumping of cameras from Germany into this country. The prices at which all the German cameras, for which he was sole agent, were listed were fair competitive prices. He contended that both the Contessa and Nettel cameras were represented in this country before 1914. The two firms were amalgamated at about the same time as the Houghton-Butcher amalgamation. The leather which was used in the Contessa-Nettel cameras was not made in Germany, but in this country, at Nottingham; he did not know where other materials for the cameras were made. The trade had decreased during the last eighteen months owing to a strike at the German factory. He believed that the trade would recover if the cameras could be sold at a remunerative price in comparison with other cameras, but Messrs. Kodak, by whom prices were largely governed, had considerably reduced their prices for one particular type of camera only during recent weeks.

This concluded the case for the parties resisting the application, except for the evidence of one or two representatives of the spectacles industry, and then Sir A. Colefax, counsel for the applicants, applied for permission to bring forward rebutting evidence, designed to clear up the points of seeming discrepancy between the two sides.

The Chairman, in giving this permission, fixed June 19 as the date for the next meeting of the Committee, the long adjournment being necessary in order that the shorthand notes of the evidence might be available.

Exhibitions.

PORTRAITS BY PIRIE MACDONALD AT THE ROYAL PHOTOGRAPHIC SOCIETY.

The eagerly awaited exhibition of the work of Mr. Pirie Macdonald, of New York, the "photographer of men," was opened to the public last week, and will remain open, free to all, until June 30.

As a portraitist who works within narrow and self-imposed limits, the reputation of this strong and individual photographer stands very high, even in this country. Doubtless this imposing show will confirm, by conviction, the lofty esteem he already enjoys here upon authority.

The sixty prints now shown are all what are known as "heads and shoulders"; not a single full or half-length, and not a woman amongst them. But although in this respect similar, their treatment differs far more than at first appears. The method of lighting is a part—a great part, indeed—of Mr. Macdonald's means of expression. Yet this, too, varies within narrow limits. He has his tricks, some of which are rather obvious; but he never descends to trick-lighting for the sake of making a smart or novel effect. Neither is he, in all cases, actuated by a desire to give his heads rotundity. Never positively two-dimensional, yet he does sometimes let the third dimension "go hang." His modelling is always clear to the understanding, but yet it is sometimes local, having little relation to the whole. It is for this reason that one is conscious here of a nose strong in relief, and there of a brow, whilst contiguous parts are, by comparison, flat. It is not for a moment suggested that the author of these works is not fully aware of such variations from a standard of logical representation. It may be his way of bringing out a sitter's characteristics. The talented painter Lembach used constantly to sacrifice a sitter's features to the eyes, into which he made the spectator delve for a psychological reading.

At any rate, it is upon the grounds of psychology that Macdonald's fame rests, and where he would have it rest. There is not a single portrait here that does not speak of the man—the

inner man; and some examples are marvellous human documents. Perhaps the most noteworthy in this respect are Theodore Roosevelt, Abram I. Elkus, Darwin P. Kingsley, S. Jennings Cox, William Rockhill Nelson, Frank Lawrence, and Dr. W. H. Wiley. On the whole, too, these seven may certainly be placed among the best in every respect, thus demonstrating the entire success of the intentions and achievements of the author's work.

One of the outstanding points of Mr. Macdonald's skill is a never-failing spontaneity. His sitters are never allowed to look posey. Most of them are caught in the living moment of some emotion; mirth, cogitation, a winning nonchalance. Or, with even more charm, a few exhibit a natural and unashamed self-consciousness, which, when it is not a sign of embarrassment, is after all the most fitting mood for a photographic portrait. It says plainly, "You want my portrait? Well, go ahead. How will this do?" In such poses there is no attempt to show the statesman wrestling with international crises, or the poet importuning his muse, as though they were nowhere near a camera. The sitter is obviously before the camera and giving his mind to the business of the moment; but none the less *the man*. The adroit use of a hand touching the face in the splendid examplea William Rockhill Nelson and Abram I. Elkus, should be noted and not forgotten.

It has been said that Macdonald makes use of a "spot-light" after he has got the normal lighting to his taste, and that this gives the high-lights that are peculiar to his style. It may be doubted whether the oily effect which this resource produces has in reality any advantage beyond that of a trade-mark. In the Roosevelt and the S. Jennings Cox, to name only two, the sitters look as if they had been caught in Broadway on a mid-day of the hottest summer.

This notwithstanding, the exhibition is one of which any portraitist would be proud. Mr. Macdonald claims it as the best he can put together. It is hard to believe he could ever surpass it.

F. C. Tilney.

FORTHCOMING EXHIBITIONS.

June 1 to 30.—Royal Photographic Society. Prints by Pirie Macdonald, of New York. Open daily from 11 to 5 p.m., 35, Ruasell Square, London, W.C.1.

August 26 to September 9.—Toronto Camera Club. Latest date for entries, July 22. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for Entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications May 22 to 27:—

Stereoscopy.—No. 14,755. Method of producing stereoscopic pictures. P. Brandt.

The following complete specifications are open to public inspection before acceptance:—

Colour Process.—No. 180,292.—Process for converting silver prints into colour pictures. Akt.-Ges. für Anilin-Fabrikation.

Coloured Pictures.—No. 180,323. Support provided with a coating sensitive to light for the production of coloured pictures. Dr. S. Schapovaloff.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Iconta.—No. 423,292. Optical, photographic, cinematographic and projection apparatus, included in class 8. Ica Aktiengesellschaft, Schandauerstrasse 72-80, Dresden, Germany, manufacturera. February 10, 1922.

Brierley (Camera Design).—No. 423,880. Photographs, photographic mounts, included in class 39, and stationery. John Hope Brierley, 19, Oxford Road, Altrincham, photographer. March 1, 1922.

Photoy.—No. 418,827. Photographic apparatus included in class 8. Harold McLean, 12, Burns Road, Fleetwood, Lancashire, photographer, and Walter Henry Utley Morley, 1, Preston Street, Fleetwood, Lancashire, shipbroker. September 24, 1921.

Devalaprint.—No. 422,727. Chemical substances for use in photography. Gerald Arthur Morris, 24, High Street, Rochester, manufacturer. January 25, 1922.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

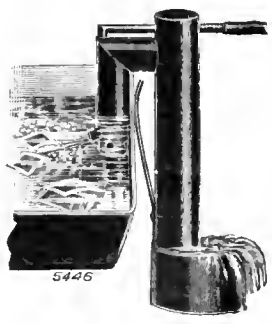
Velox (Design).—No. 421,046. Photographic papers. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials.

Velox (Two Designs).—No. 421,423 Photographic papers. Kodak, Ltd., Kodak House, Kingsway, London, E.C.2, dealers in photographic materials

New Apparatus.

The Ensign Water Circulator. Made by Houghtons, Ltd., 88-89, High Holborn, London, W.C.1.

Those who have attended meetings of the Royal Photographic Society know the mental originality and manual dexterity of Mr. K. C. D. Hickman, who is the inventor of this appliance for the washing of negatives and prints. The "Circulator" is a piece of apparatus essentially different in principle and construction from the numerous washers which have come upon the market. It is an accessory for attachment to a dish or any approximately straight-sided and shallow vessel, which performs two distinct functions. It delivers the water into the vessel in a somewhat violent manner, and it also siphons it out again as fast as it enters. In his recent paper on the washing of plates and prints before the Royal Photographic Society, Mr. Hickman showed the special merit of an



5446

5447

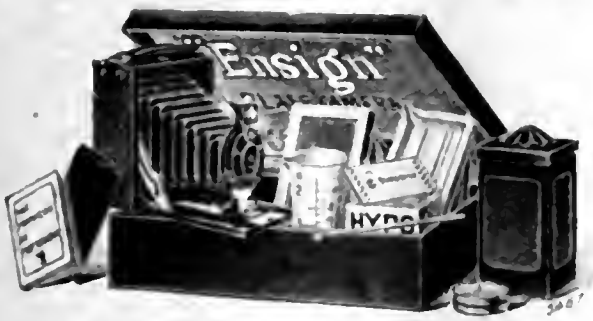
active movement of the supply of water in the removal of hypo from plates or prints. The "circulator" is an apparatus embodying the features which Mr. Hickman's scientific measurements showed to be highly advantageous for effective washing. Our own tests of the appliance, although not nearly so exact or exhaustive as those described in Mr. Hickman's paper, fully convince us of the efficiency of his "circulator." In the first place when the appliance is fixed to the side of a developing dish, as

shown in the drawing, and the rubber tube connected to the water supply, a most active circulation of water is produced in the dish on turning on the tap. We filled a dish with dark permanganate solution. On setting the circulator in operation every trace of the permanganate colour was removed in less than a minute. Without touching the tap we disconnected the rubber tube, refilled the dish with permanganate solution, of the same strength as that previously used, and let the open stream of water run into it. From two or three minutes were required to get rid of the permanganate colour, thus showing, by a rough and ready test, the much greater efficiency of the appliance over the time-honoured method of allowing water to run directly into dishes containing negatives or prints.

Further tests were made by staining fixed out plates with dye and comparing the times required for removal of the dye (with the same water consumption) when using the circulator, and when employing water straight from the tap. In these circumstances, which represent the conditions in the removal of hypo, the circulator showed to still better advantage in comparison with the open tap than in the test with permanganate.

The circulator is, in fact, a most ingenious and scientific combination of a water delivery nozzle which spreads the water supply in all directions in a dish and a kind of exhaust pump which is continuously drawing off the delivered water from near the bottom of the dish. In using it, it is of course necessary that the dish stands in a sink or in some other place which allows of the water passing away. The apparatus is supplied in two models, one of solid brass, price 27s. 6d., and the other of Duro glass, price 8s. 6d. Without question the apparatus is the most efficient accessory for the washing of prints in ordinary dishes which has yet been produced.

Ensign Plate Camera Outfits.—Messrs. Houghtons send us one of the eight outfits which they have placed upon the market specially in connection with the £3,000 competition for photographs from negatives on dry-plates. Each outfit includes a dark-room lamp, printing frame, dishes, measure and a supply of chemicals, together with the camera itself, which may be one of the magazine pattern or a folding model. The No. 1 outfit, including a 3½ x 2½ Ensign-Mascot magazine camera, costs 18s. 6d.,



whilst the No. 8, which is the one sent to us, provides an "Ensign-Klito" quarter-plate camera with f/8 lens, time and instantaneous shutter, focussing scale, folding brilliant finder and two single metal plate-holders, price £3 2s. 6d. The outfits are attractively boxed, and the opportunity to purchase the requisites for a beginning with a camera in this form will no doubt serve to make recruits for the competition and for photography.

Business away from the Studio.—Those who may not realise the great amount of portrait business to be got, particularly during the summer months, by going after sitters instead of waiting for them to come to the studio, should on no account miss reading an 8-page leaflet which describes the experience of a portrait photographer in seeking these new avenues for sitters, and, in the sequel, trebling his earnings. The booklet is issued by Messrs. Sands, Hunter & Co., 37, Bedford Street, Strand, London, W.C.2, and will be sent to any *bona fide* professional photographer free on application.

Photographers on Margate Beach.—We learn from the local papers that £320 was paid last week for the rights of taking photographs on Margate beach during the present season.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Monday, June 12.

Southampton Camera Club. Evening Outing.
Wallasey Amateur P.S. "Focussing." W. Hayes.

Tuesday, June 13.

R.P.S. "Matt Surface Plates." F. T. Usher (Messrs. Elliott & Sons, Ltd.).
Bournemouth Camera Club. "Transferotype Process." A. B. Snell.
Exeter Camera Club. Exhibition. Portfolio by F. Judge.
Hackney P.S. "Portraiture Without a Studio." S. Woodhouse.
Manchester A.P.A. "Romantic in Landscape." F. C. Tilney.

Wednesday, June 14.

Dennistoun Amateur P.A. Criticism of Outing Prints.
Rochdale Amateur P.A. "Lighting Effects in Studio."

Thursday, June 15.

Hackney Phot. Soc. Outing—St. Albans to Harpenden.
Hammersmith Hampshire House Phot. Soc. "Exposure and Development." M. O. Dell.

Friday, June 16.

R.P.S. Pictorial Group Meeting. "The Final Support in Carbon Printing." A. C. Braham F.R.P.S.

Saturday, June 17.

Edge Hill Camera Club. Outing to Woodchurch and Irby.
Hackney Phot. Soc. Annual Sports.
Sheffield Phot. Soc. Outing to Ford and Povey.
South Glasgow Camera Club. Outing to Kilbarchan.
Wallasey Amateur Phot. Soc. Outing to Manchester.

CROYDON CAMERA CLUB.

A "Print Display" brought the formal session to a close last week. In point of numbers the prints were poor indeed; in quality, there were some good things on the walls, including three Carbro enlargements, fine technically and pictorially, by the hard-working president, Mr. John Keane. If it had not been for him the "display" would have chiefly displayed the wall-paper.

The criticisms were interesting, mainly in showing the different standpoints taken by the artist, as represented by Mr. Handel Lucas, and by the photographic pictorialist, as represented by Mr. Harpur, whose conception of Art has always been kept within exceedingly convenient limits, purely due to the fact that beyond the art of the camera, other aspects have never interested him at all.

Despite these limitations, it cannot be gainsaid that for the budding pictorialist Mr. Harpur, as contrasted with Mr. Lucas, is the more useful of the two. The conventionally tasteful laws of arrangement or composition (whichever term is preferred) are fully understood by Mr. Harpur, and he can give sound advice on same lines in tuning-up to exhibition standard. Any picture, however, which does not fall within the, more or less, obvious lines of approved composition is passed over in silence as unworthy of remark, provided no patent defects appear. If the contrary, the lot of a rat in the jaws of a terrier is happy by comparison.

The criticisms of the artist, Mr. Lucas, are directed in an exactly opposite direction. Rarely, if ever, does he descend from the general to the particular, even if he has personally descended from canvas to the camera, for reasons best known to himself, and welcome, indeed, are the clear indications of far bigger things, and finer conceptions, than are to be found in the usual stock-in-trade of the critic born of photography.

If Mr. Lucas finds, for instance, his pet doctrine of "visual repose" firmly rooted in a picture, then even glaring technical faults weigh but little in the balance. Consequently, a very poor photograph, judged purely by photographic standards, may be extolled, and excellent technique overlooked. But never condemnation of anything. As an ecclesiastic he would be painfully unsound on Hell.

The rest of the evening was devoted to a discussion on the weak position of the pictorial element. Certainly not for want of technical instructions, as strong fixture lists, carried through in the past by members and kind outside friends, amply prove. Some of the veteran pictorialists in the club have got tired, and all must tire eventually, but fresh blood has lamentably failed to come forward. And why? A strong endeavour is to be made to find out, and apply the remedy.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given of the dissolution, by mutual consent, of the partnership between Herman Matz and Mayer Liebermann, carrying on business as photographic printers and enlargers, at 45/47, Cheetham Hill Road, Manchester, under the style of Progress Art Studios. All debts due to and owing by the late firm will be received and paid by Mayer Liebermann.

THE PUBLIC EXAMINATION of Albert Young (trading as Fradelle & Young) was held at the London Bankruptcy Court on May 30, before Mr. Registrar Mellor. The receiving order was made on March 16, 1922, on a creditor's petition, the act of bankruptcy being the failure of the debtor to comply before February 3 with the requirements of a bankruptcy notice. The Official Receiver, in his observations on the case, reported that the debtor, at the age of 13, entered the employment of Mr. Fradelle, photographer, of Regent Street, by whom he was employed until the latter's death in 1884. He then, with a capital of about £50, commenced a similar business on his own account at 17 Regent Street, W., and continued it for about three years. About the end of 1885 he purchased his late employer's business at 246 Regent Street for £1,000, and carried on that business under the style of Fradelle & Young, until the lease expired in 1897, when he removed to 283, Regent Street, W., and about 1915, in consequence of a serious illness and bad trade owing to the war, he closed the business. About April, 1917, he took a shop at 37, High Street, Notting Hill Gate, W., and recommenced business as a photographer. In June, 1921, he removed to 41, Museum Street, W., and his business was chiefly taking group photographs of banquets. He attributed his insolvency to the loss of £80 in Farrow's Bank, to the removal from Notting Hill Gate to Museum Street, and to ill-health. The statement of affairs showed liabilities expected to rank amounting to £539 5s. 11d., and net assets estimated to produce £96 14s. 4d., thus showing a deficiency of £442 11s. 7d. The public examination was concluded.

NEW COMPANIES.

CHALLENGE MANUFACTURING CO., LTD.—This private company was registered in Edinburgh, on May 24, with a capital of £18,000 in £1 shares. Objects: To carry on the business of manufacturers of and repairers of and dealers in cameras, enlarging and projection apparatus, stereoscopes, lenses, shutters, etc. The subscribers (each with one share) are: J. Johnson, junr., 51, Buchanan Drive, Cambusland, C.A.; D. B. Mungo, 173, St. Vincent Street, Glasgow, solicitor. The first directors are not named. Qualification: £100 shares. Registered office: 173, St. Vincent Street, Glasgow.

ASHBY-NOLA, LTD.—This private company was registered on May 23, with a capital of £1,000 in £1 shares. Objects: To carry on the business of commercial and art photographers, cinematographers, catalogue illustrators and printers, trade photographers and enlargers, technical and portrait photographers, magazine and trade journal illustrators, artists, designers, etc. The first directors are: R. A. Horan, 14, Edgecombe Road, S.E., photographer; H. S. Macintosh, "Deancot," Hampstead Norris, Berks, editor. Qualification: £10. Remuneration: £1 each per annum (chairman £3). Secretary: J. Casanova. Registered office: 22, Northumberland Avenue, W.C.2.

UNDERWOOD COMMERCIAL STUDIOS, LTD.—This private company was registered on May 24 with a capital of £2,000 in £1 shares (1,500 preference). Objects: To take over the business of commercial and stereoscopic photographers carried on by H. Featherstone and R. C. Levitt at Dwydia Chambers, High Holborn. The first directors are:—H. Featherstone, 11, Wilbury Avenue, Hove, Sussex; R. C. Levitt, 6, Alexandra Mansions, Cricklewood. The said H. Featherstone is permanent chairman, subject to holding 100 shares. Qualification of ordinary directors, 1 share. Remuneration as fixed by the company. Registered office: 3, Budge Row, Cannon Street, E.C.4.

AIRCO AERIALS, LTD.—This private company was registered on May 18, with a capital of £2,000 in £1 shares. Objects: to carry on the business of manufacturers of and dealers in photographic materials and apparatus, photographs, pictures, prints and other works of art, aerial, commercial and general photographers, manufacturers of aeroplanes or parts thereof, etc., in England, U.S.A., and elsewhere. The first directors are:—Capt. S. W. Hiscocks, Grove Park House, Kingsbury, Middlesex (permanent); H. A. Peters, Holmesley, 74, Finchley Lane, Hendon, N.W. Qualification: £1. Secretary: S. W. Hiscocks. Registered office: 15, Furnival Street, E.C.4.

ARTHUR HENTSCHEL STUDIOS, LTD.—This private company was registered on May 24, with a capital of £600 in £1 shares. Objects: To acquire the undertaking of Ellen E. Butcher and Carl Hentschel, and to carry on the business of proprietors and producers of illustrations, engravers, printers, lithographers, photographic printers, advertising agents, etc. The first directors are:—Ellen E. Butcher, 16, Casella Road, New Cross Gate, S.E.14, secretary; Carl Hentschel, 70, Wynnstay Gardens, W.8, photo-engraver; Leonard Hewland, 38, St. Ann's Chambers, E.C.4, secretary. Qualification (except first directors): £50. Remuneration: 10 guineas each per annum (chairman 20 guineas). Secretary: Ellen E. Butcher. Registered office: 90, High Holborn, W.C.1.

News and Notes.

WILLESDEN PHOTOGRAPHIC SOCIETY.—Mr. H. F. James, 54, Nicoll Road, London, N.W.10, has been appointed hon. secretary.

CAMERA HOUSE JOURNAL.—The June issue of Messrs. Butcher's house organ contains particulars of the latest seasonable goods, including the series of Carbine, Cameo and Klimax cameras fitted with *f*/4.5 lenses.

ENSIGN MESSENGER.—Dealers will find particulars of many new goods and other trade announcements in the current issue of the "Ensign Messenger," just issued by Messrs. Houghtons, 88-89, High Holborn, Lonodon, W.C.1.

ROYAL PHOTOGRAPHIC SOCIETY.—At a recent meeting of the Council 19 applications for the Fellowship were considered. The following members were elected:—Olaf Bloch, J. A. Lomax, J. Manby, B. V. Storr, F. C. Toy and Oswald J. Wilkinson.

THE TRAILL-TAYLOR LECTURE.—The twenty-fifth annual Traill-Taylor Memorial lecture will be delivered at the Royal Photographic Society, on October 10, by Dr. Reginald S. Clay, who will take as his subject "The Development of the Photographic Lens from the Historical Point of View."

CITY SALE AND EXCHANGE.—A new branch, making seven in all, has just been opened by the City Sale and Exchange at 52, Cheapside, London, E.C.2, within two doors of Bow Church. A full stock of both professional and amateur requisites, new and second-hand, will be kept at this branch, which will be under the management of Mr. Hume.

THE LATE J. CRUWYS RICHARDS.—We much regret to hear of the death of Mr. J. Cruwys Richards, for many years a leading member of the Birmingham Photographic Society. By profession a designer of stained glass, Mr. Richards had the true artistic temperament, and took a great practical interest in the early movement in pictorial photography. He was one of the most successful exponents in this country of the gum-bichromate process, and was the author of a manual of this process entitled, "Practical Gum-Bichromate."

£3,000 COMPETITION.—No. 2 of the Trade Bulletin, dealing with the activities of the All-British competition, in which £3,000 in prizes is to be awarded for photographs taken from negatives on plates, gives particulars of the latest literature which is being issued by the promoters in the form of show-cards, window bills and posters, poster stamps and stereos for use in local newspaper advertising. It is announced that the following have consented to act as judges of the competition:—Sir William Orpen, Mr. George Robey, Mr. Gordon Selfridge, the Editor of "The

Graphic," and Mr. W. L. F. Wastell. All particulars of the competition are obtainable from the headquarters at 4, Oxford Street, London, W.1. The first round of the competition closes on June 30.

Correspondence.

THE COSTING OF STUDIO PORTRAITS.

To the Editors.

Gentlemen,—

Pelham Swinton is a very good man.
He tries to teach us all he can.
But if we go by the costings in his book,
Our clients would be afraid to have their photos took.

LAWLEY BROS.

Gainsborough Studio, Penzance,
May 29

We forwarded the above criticism to our contributor. His reply is as follows:—

My confrères, having known the throes
Of threading my entangled prose,
Reply in lines which do not scan
As vengeance on a nervous man.

I have no passion to upset
The value of the Cabinet,
Nor yet restrain my friends in Art
From charging lower for the Carte;

But factors which a cost enhance
Vary with the circumstance,
And what is guineas in the town
Is in the village half-a-crown.

My critics' costs must be below
Those of a West-End studio;
And hence their fees must show a state
Appropriately moderate,
Lest customers should look askance
Upon fresh Pirates of Penzance;

Or—in plain English—they must go by their own costs, and not by mine.

PELHAM SWINTON.

June 5.

SYSTEM IN HALF-TONE OPERATING.

To the Editors

Gentlemen,—Mr. Corkett, director of the Pictorial Machinery, Ltd., 7, Farringdon Road, has called my attention to an article printed in the March 31, 1922, issue of the "British Journal of Photography." This article was written by Mr. E. A. Bierman, F.R.P.S., and the subject was "System in half-tone operating."

In paragraph 3 Mr. Bierman states that any system of half-tone photography that does not permit of the making of half-tone negatives from any given copy and extension, and with all screen rulings with the same stop and exposure time, is a failure. This paragraph is not in his exact words, but it does express his thoughts as best I could interpret them.

The Douthitt system of making half-tone negatives is based on the optical law that light varies as to the square of the distance, together with the physical law, that any opening double the diameter of a known opening has four times the area. As the areas of the screen openings vary according to the screen rulings, and as the amount of light passing through these screen openings is in proportion to the size of these openings, it is apparent that we must set the screen in front of the sensitive plate according to these optical laws if we expect to obtain negatives with identical tone gradation of the copy. The screen must be set so that not only good dense dots are formed on the plate, but that also the tone gradation of the copy is retained, or so the operator can control the tone gradations, and thereby improve such copies as do not make a pleasing picture.

The screen separations listed in "Penroses Annual" are optically correct, and are the only ones that enable the operator to reproduce the tonal value of the copies. You will, of course, understand that we do not under all conditions and circumstances strictly adhere to the screen separations listed, because we have found that for certain classes of negative making, such as for the offset process, or for newspaper work that is to be stereotyped, the screen separation has to be varied to meet the needs of the type of work being done. I do, however, contend, and can prove in practice, that for any type of negative with any screen, the screen separations have to vary on a 4 to 1 ratio, if identical tonal results are to be obtained.

When making half-tone exposures at a certain extension the constant factors are:—

Screen opening.
Extension.

Variable factors are:—
Screen separation.
Stop diameter.
Exposure time.
Intensity of illumination on copy.

The screen opening and extension are really constant factors, while the screen separation and stop diameter are only variable according to the type of negative desired. This leaves only the exposure time and intensity of illumination as real variables. Heretofore we have changed the exposure time for the different screen rulings, but there is no reason why the exposure time cannot be constant if the intensity of the illumination on the copy is varied for the various screens.

We will take, for example, a condition where the lights are placed 50 inches from the copy, and the exposure time is correct for the 150 screen. The light distance for some of the other screens would be as follows:

Screen.	Light-distance.
150	50 inches
120	40 ,,
100	33 ,,
75	25 ,,

By changing the intensity of the illumination on the copy we are enabled to follow all optical laws, as to screen, separation, etc., obtain negatives of identical tone gradation, and keep the exposure time constant for any screen.

In the last sentence of paragraph 5 Mr. Bierman states: "The only possible way to obtain correct gradation in a screen negative is by the use of only one stop." This is correct only to a certain point. Due to the wet plate being a highly blue-sensitive photographic medium, and as considerable copy is received for reproduction that is quite blue, it is apparent that the copy will photograph lighter than it appears to the eye. In cases of this kind it is necessary to use more than one stop, so as to overcome the defects of the colour sensitiveness of the wet plate. On the other hand, when the copy is a true grey scale, and the tones will photograph on a wet plate in the same value as the eye sees them a one-stop exposure is all that is necessary.

I have found that the same optical laws apply to all half-tone photography irrespective of the photographic medium, wet plate, dry plate, or orthochromatic emulsion; the apparent deviations from these laws being caused by type of copy being photographed contrasty or flat, and the character of the photographic medium. Take a "Solio" print which is opposite in colour sensitiveness to the wet plate, and a one-stop exposure will prove very satisfactory, while if the copy is a retouched one in which the artist has used considerable pigment that has a bluish cast, a one-stop exposure will not always prove satisfactory. In colour separation negative-making direct on dry plates the one-stop exposure is correct, because the

colour filter and the colour sensitiveness of the plate are co-ordinated. The same is true of collodion emulsion.

In defence of the Douthitt system I will only state that it has been our aim to code all the optical laws pertaining to half-tone photography in such a manner the operator can readily understand the fundamental principles: install the necessary fittings on the camera and lens to enable him to use these laws without any calculations on his part, and, lastly, to assure that he will produce uniform negative on any screen at any bellows extension.—Very truly yours,

(Signed) RALPH GRENELL,
Manager,
Douthitt Diaphragm-Control Corp.

THE PHOTOGRAPHIC CONVENTION.

To the Editors.

Gentlemen,—In your programme for the Convention you state that I am to lecture during the week. Although I had the honour of an invitation to do so, I explained to Mr. G. B. Clifton that it was impossilbe for me to attend. I hasten to correct the error so that those who are looking forward to a pleasant time may be under no apprehension that I am going to lecture at them.—Yours sincerely,

June 2, 1922. W. L. F. WASTELL.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

W. B.—The business of Mr. Moore is now carried on as the Thurlow Manufacturing Co., 58, Thurlow Street, Walworth, London, S.E.17.

F. A.—For beach work, groups or single subjects, where the camera has not to be carried about very much, a 5 x 4 or half-plate reflex would be a very good choice. We would advise you not to get a lens of larger aperture than about *f*/6. For the half-plate reflex a focal length of 8 or 9 ins. would be suitable The reflex is not at all a suitable camera for architecture, as it is very awkward in use on a stand, and usually has not the rise of front required in architectural photography, and never a swing back.

H. B.—(1) As you are likely to have sun upon the glass, we think a greyish green or a neutral grey would be the most suitable colour for the walls. (2) A plain linoleum will be the most useful, as it will serve with indoor or outdoor backgrounds. A large rug or small carpet square can be used with the latter if desired, and will add to the appearance of the studio. (3) You cannot do better than fix white nainsook curtains, as described in "The Portrait Studio." All the glass should be covered with these, and the black blinds used while the sun is on the glass.

H. S.—The 5-in. Dallmeyer would, we think, work better with the 10-in. lens than with the 7¾. There would be no loss of rapidity for the same equivalent focal length, as the 10-in. primary image, being larger than that of the 7¾, would require less magnification. We think that there is an advantage in the Dallmeyer double negative; especially at low magnifications, it gives a better field and less distortion, while its large diameter enables a larger plate to be covered; with a "back focus" from the negative lens the 10-in. positive and 5-in. negative should cover a half-plate with a magnification of three diameters, and an intensity of *f*/22 at full aperture.

J. D.—We do not know the apparatus you mention, but presume it is one in which the negative is illuminated by diffused daylight. There would be no objection to fitting a condenser for the use of the Fullolite electric lamp, but although this lamp is considerably diffused it would still be necessary, we think, to vary the position of the lamp according to the degree of enlargement in order to get uniform illumination on the easel. Apart from this adjustment you should be able to use the camera according to the scale provided for use with daylight, but it is also to be borne in mind that some lenses which work exactly to focus with daylight do not do so with an electric light. But you could easily find out for yourself if an enlargement which is sharply focussed yields as sharp a picture on the bromide paper.

C. W.—We do not understand what you mean by "the extra focal distance of a cinematograph lens," and have never heard of the formula which you give. But as you do not say what the symbols represent, we may perhaps not fully understand your question. We understand "extra focal distance" to mean the distance of an object which is obtained in focus with a given lens, less one focal length of that lens. In projection the lantern slide or film is, of course, the object. The formula for the "extra focal distance" in these circumstances is the focal length of the lens divided by the number of times of enlargement, that is to say it is usually a comparatively small fraction of an inch in excess of the focal length. If, on the other hand, you define "extra focal distance" as the distance of the projection lens from the screen, then the "extra focal distance" is equal to the focal length multiplied by the number of times of enlargement.

O. R.—(1) To illuminate the white background the glass must extend to the extreme end of the studio. You must light your sitter independently of the light falling upon the background. (2) We do not think this necessary or desirable. (3) The arrangement for specimens is quite good. You do not need any light lower than 4 ft. from the floor. (4) In view of the probable lengthening of the studio we should advise you to have 12 ft. run of glass at least, so that you will be able to illuminate groups fairly evenly. We take it that you only intend to work from one end of the studio. (5) The angle of the roof has little effect upon the lighting. The studio will look better, and the construction be probably stronger if you have the two sides of equal pitch, say 45 deg. (6) No difference in colour is needed for using panchromatic plates. (7) White inside, and outside, too, if possible. (8) No. (9) We do not think that this matters very much if the proposed dark-room is at the dark end. The side farthest from the glass would probably be the better. (10) The Aldis 8-in. would be a very suitable lens for full length cabinets or postcard work generally, but for large cabinet heads you should use an 11-in. or 12-in. lens if possible. Most photographers use a 16-in. lens for these. The 8-in. Aldis would be excellent for enlarging.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3241. Vol. LXIX. FRIDAY, JUNE 16, 1922. Price Fourpence.

Contents.

SUMMARY.

Mr. Raymond E. Crowther contributes an article describing the new desensitisers which have been worked out by Dr. E. König, and which have been named pinakryptol and pinakryptol green. These desensitisers are at least as effective as phenosafranine, and are free from staining tendency. Pinakryptol has a much smaller effect than either phenosafranine or pinakryptol green on the Watkins factor of a hydroquinone developer. (P. 351.)

In a leading article we refer to the chief conditions which require to be observed in the use of the customary process of sulphide toning, and add some hints on the method of toning with liver of sulphur. (P. 351.)

The further portion of Mr. F. F. Renwick's review of recent progress in photographic manufacture and research deals with colour photography, colour sensitisers and desensitisers, development, radiography and emulsions. (P. 354.)

Dr. O. Mente has described a very ingenious method of copying water-marks in paper. A sheet of bromide or gaslight paper is uniformly exposed, developed, fixed, washed and bleached in mercury bichloride. It is exposed through the paper to ammonia vapour, the design of the water-mark being reproduced by the differential penetration of the ammonia through the different thicknesses of paper forming the water-mark. (P. 353.)

A cause of imperfect fixation, which is sometimes overlooked, is the dilution of the hypo bath which results from the insertion and withdrawal of prints without draining. (P. 350.)

Mr. A. H. Hall recommends a bleacher of potass ammonium chromate, or ammonium bichromate, as free from the objection of giving yellowish whites in the re-development of prints on warm-tone bromide papers for improvement of their colour. (P. 363.)

At the Royal Photographic Society, on Tuesday evening last, Mr. F. T. Usher showed the remarkable non-halative properties of the new "Matt Surface" plates introduced by Messrs. Elliott & Sons, Ltd. (P. 361.)

A method of making collotype plates from negatives by using the ordinary process of mercury intensification is the subject of a recent patent by M. de 'Sperati, who also has patented a process for making collotype plates on celluloid. (P. 357.)

A further patent of Kodak, Ltd., for a vertical self focussing enlarger will be found under "Patent News." (P. 358.)

Some remarkable snapshots by artificial light, taken on plates which had been extra-sensitised, have been published by the French Photographic Society. (P. 349.)

A handy method of keeping miscellaneous small articles where they can be found in an instant is the subject of a paragraph on page 350.

The method of Reichel for toning P.O.P. prints red may be recalled in reference to variations in gold toning. (P. 350.)

EX CATHEDRA.

Ultra-Sensitising. In his "Paris Notes" a few weeks ago M. Clerc alluded to the method of extra-sensitising of Autochrome plates worked out by M. Monpillard about a year before the war and only recently disclosed. The process consists essentially in the addition of a solution of silver chloride in ammonia to the mixture of the colour-sensitising dyes. The current issue of the Bulletin of the French Photographic Society contains a long paper on the subject by M. L. Gimpel, who was a collaborator of M. Monpillard in the practical employment of the process. Apart from the importance of the method in permitting of hand-camera exposures on Autochrome plates, other than Autochrome workers will read with more than ordinary interest the description of M. Gimpel's success with ordinary plates extra-sensitised by the Monpillard method. Several photographs from negatives taken with plates treated in this way are reproduced, among them a scene in a bar on a Parisian boulevard lighted only by mercury-vapour lamps. At the aperture of *f*/4 this plate received an exposure of a quarter of a second with the camera held in the hand. We have in preparation a full translation of M. Gimpel's paper, which we expect to be able to publish within the next week or two.

* * *

Desensitising. The way in which the process of desensitising with phenosafranine has come to the front as new and useful practice in negative-making provides an interesting object lesson in the evolution of photographic methods. For desensitising, as a process, is by no means new. The literature of the past twenty or thirty years contains many papers on it; and in that rich yet arid work, "Investigations on the Theory of Photographic Processes," by Sheppard & Mees, the properties of mineral oxidising substances as desensitising agents are the subject of detailed notice. Had these properties been regarded from a different angle, desensitising as a practical process would, no doubt, have come years ago. But by the above investigators as well as by Vidal, Sterry and others the desensitising of an exposed plate was considered solely in relation to the still elusive problem of the nature of the latent image. The convenience in practical work of a solution which partially destroyed the sensitiveness of an emulsion whilst leaving the latent image intact, evidently did not occur to these experimenters, intent on the infinitely more fundamental object. The two-fold moral of the incident is that the practically minded must study the work of the scientific people for possible applications of it not contemplated by the latter, who also, as far as possible, should describe their experimental results in plain language whatever technicalties they may admit into their discussion of them.

Red Tones on P.O.P. The production of prints of distinctive warm tones by means of gold salts is one of the branches of print making which has been neglected of late years, as a result, no doubt, of the favour bestowed on development papers and on sulphide toning and its variations. The only process which may be said to have secured a measure of popularity is that in which a sulphide-toned print is toned in a gold-sulphocyanide bath, yielding an image of red chalk to crimson colour. Nevertheless, the great variations in the colour of gold, according to the state of division of the metal, justifies the belief that experiment by those who have specialised in colloid chemistry should result in useful toning processes of this kind. In this connection it may be interesting to recall the gold toning which was employed for the making of the red component of a three-colour print according to a process patented by Reichel in 1903. A P.O.P. print was toned in a bath containing gold sulphocyanide, sodium iodide and potassium carbonate. We have still in our mind the excellence of some specimens of the Reichel three-colour process, which, however, like many another of the pre-Autochrome days, did not come to a commercial stage, but we never saw the component images separately. According to the specification, strontium or magnesium salts were necessary constituents of the P.O.P. emulsion.

* * *

Workroom Odds and Ends. The admirable maxim that there should be a place for everything and that everything should be in its place is one which cannot be too strictly applied to the photographic workroom, in which there is a tendency for odds and ends to accumulate in a muddle in drawers, and for much time to be lost when some particular item is wanted quickly. Here is the opportunity for making really good use of empty plate boxes, or at any rate of those which are of moderate size, such as quarter-plate or 5 x 4. From dealers in office requisites there can be bought "drawer boxes," a very good make of which is Stone's. These consist of a deep drawer sliding in an open-fronted casing. The boxes are made in a whole series of sizes, so that one can be chosen to take conveniently seven or eight of the empty plate boxes, placed on their ends one behind another. To the bottom of each plate box is glued a stout flap, serving to lift the box from its place, whilst a label is fixed to one end of the cover of each box and marked with the contents. By this arrangement, several drawer boxes provide storage for a score or more of various odds and ends, such as print clips, lens caps, flanges, diaphragms, camera screws, corks, glass stoppers, adhesive labels, and even such little things of workroom utility as tap washers and electric fuse wire. The means for finding any one of these things in an instant saves a good deal of time in the course of a year.

* * *

Hypo Strength and Economy. Although it is an unwise policy from every point of view to be sparing in the use of hypo in the making of negatives and prints, yet there are ways of wasting hypo which, perhaps, are unsuspected by many photographers. It is imagined that the mere use of plenty of hypo solution necessarily implies that ample provision is being made for efficient fixation of prints. Nevertheless, the manner in which prints are handled may do much towards wasting hypo, and, what is worse, creating a false impression that all is well as regards fixation. We have often seen an operator in a printing room transferring prints from the developer to the fixing bath without a pause, so that the latter is continuously diluted by the developer, or by the wash water, in the case in which an intermediate washing is given between developing and fixing. It is scarcely realised to what a considerable degree the hypo solution is reduced in strength by this practice. The amount of developer or water conveyed into the fixing bath is not noticed, for the reason that, in removing prints from the fixer the same procedure is adopted, a considerable quantity of hypo being removed through omission to allow each print to drain before transferring it to the wash water. Thus, in the course of a day's continuous work, the fixing bath can become greatly reduced in strength, not as the result of performing its proper work in dissolving the surplus emulsion, but through physical transference of the hypo into the washing tank. As a result, the hypo bath comes into a weakened condition, in which it is liable to produce prints which within a little time will show the brownish stains characteristic of imperfect fixation.

SULPHIDE TONING.

At a recent meeting of the North Middlesex Photographic Society the pros and cons of sulphide toning formed the subject of discussion, and upon a vote being taken a majority pronounced against the process, the opinion being expressed that untoned prints upon "warm black" papers, with either a white or cream base, were better suited for good pictorial work.

Sulphide toning, that is to say the bleaching of a print and the subsequent darkening of it in a solution of sulphide of soda or similar salt, appears to be a simple matter, but many points have to be observed if entirely satisfactory results are to be obtained. For while a small proportion of sulphide-toned prints leave nothing to be desired, in a much larger number of cases the result is to spoil good black and white prints. Leaving out the question of colour, the greatest faults are a clogging of the shadow details, which sometimes causes a semi-bronzed appearance, and a general degradation of the high-lights. Prints which are to be toned must be of a much better quality than is required for black and white, since the image must be sufficiently vigorous to give a good colour, but must not be in the least heavy in the shadows. To obtain this result a good negative is necessary, as it is not allowable to compensate for lack or excess of contrast by such dodging in exposure and development as would give satisfactory results with untoned prints. A good colour can only be obtained by giving fairly full development; the poor stale mustard colours so often seen result from a thin image which, in turn, may be due either to the use of a weak negative (one not allowing sufficient exposure to be given to the shadows before the lights are printed through) or to a dense or hard negative which requires a long exposure to penetrate the high-lights and a short development to avoid loss of shadow detail. It is not difficult to judge by inspection of a black print whether it will tone satisfactorily or not; a suitable one looks clear and bright by reflected light and almost equally vigorous by transmitted light.

Other causes of poor tones and unevenness are imperfect fixation, either by reason of too short an immersion in the hypo bath or the use of a solution heavily charged with silver. In either case the silver salt remaining, either evenly all over the paper, or unevenly by reason of the prints sticking together, darkens upon immersion in the sulphide bath, and gives a cream or light brown tint over the high-lights.

Even if fixation be thorough, the prints will suffer if any trace of hypo be left in them before bleaching. The

bleaching solution, being largely composed of potassium ferricyanide, forms Farmer's reducer with the hypo, reducing the image either evenly or locally to such an extent that it becomes too weak to give a rich tone. Carefully-made prints, which are rather too weak to give a good colour, should always have a preliminary immersion in the sulphide solution before bleaching, as this to a great extent avoids the appearance of the objectionable foxy colour.

Those who are not satisfied with the two-stage method of toning will do well to adopt a single-solution method, such as hypo-alum or the simpler one of liver of sulphur. The former is rather troublesome for the worker whose space is limited, and the "liver" method is therefore recommended. The tones obtained with it are a rich, warm brown, more nearly resembling the "standard brown" of the carbon printer than a true sepia, but even with weak prints the colour is good, although lacking in richness. One great advantage is that a great variety of tones can be obtained at will. The time of immersion influences the colour exactly as in toning printing-out papers; the only difference is that the longer the immersion the warmer the colour, a very short immersion giving a warm black, while longer ones give various shades of purplish brown till a warm sepia is reached. It is necessary to say that the tones obtained vary greatly with different brands of paper, as does also the speed of toning. In a recent experiment it was found that with two prints on different papers, one toned to a warm sepia suggestive of Seltona without the salt bath in less time than the other assumed a purple brown such as is obtained on the same paper with the salt bath. With a longer immersion of the purple print a good warm brown was secured.

The process is a simple one, the bath consisting of 60 grains of liver of sulphur ("potass. sulphurata") dissolved in 80 ounces of water to which about 10 minims of .880 ammonia should be added. This should be used at a temperature of 80 degs. to 100 degs. Fahr., some papers toning readily at the lower temperature. Although all papers do not need it, it is advisable to harden the prints five minutes in 10 per cent. formaline solution, giving a slight rinse before immersing in the toning solution. After toning, the prints should be washed until all odour has disappeared, and if the solution is at all turbid it is well to swab the surface with cotton wool before drying. If blisters appear, they are probably due to too sudden a change in temperature in transferring to the washing water, in which case the first rinse should be given in tepid water.

It should be noted that the tone becomes perceptibly warmer during the final washing, so that care should be taken to arrest the toning while the colour is a little cooler than is desired for the finished print. But, as is the case with all toned prints, the colour becomes colder upon drying, so that very little allowance need be made. The most important point appears to be the selection of a paper which will easily give the desired tone.

NEW DESENSITISERS.

It is somewhat more than a year since the process of desensitisation—the outcome of a long and tedious research by Dr. Lüppo Cramer—was introduced to readers of "The British Journal of Photography." The interest which has been taken in the subject throughout the world in the interim affords sufficient justification for an attempt to "report progress."

In this country the solution "Densensitol" has enabled photographers to try out development of highly sensitive plates in bright light, and so satisfy themselves of the merits of the invention. Within the last six weeks a well-known firm of plate makers has announced the manufacture of plates backed with desensitising composition, thus simplifying the application of the process and placing it at the disposal of all to whom the making up or dilution of solution constitutes "too much trouble." In France photographers have had at their disposal a choice of desensitising agents of varying efficiency, some of which do not suffer from the staining tendencies of phenosafranine. There seems to be no room for doubt—at least, as far as reduction of sensitiveness is concerned—that phenosafranine is the most efficient substance hitherto available, and its adoption by the photographic section of the Japanese Air Force is practical testimony to this contention. Anyone who has used this dye, however, must have been struck by the extraordinary staining power of even a 1 : 5,000 solution; if such a solution be employed as a desensitising bath before development it is very difficult to remove the last traces of dye from the film by simple washing, especially if the glass of the negative has been coated with a substratum of tanned gelatine in the process of manufacture. The multitude which uses film is virtually debarred from the advantages of desensitisation by phenosafranine, the two gelatine coatings of the substratum necessitating so long a washing that softening and frilling more than counterbalance the advantage of being able to manipulate the development by lamp light or candle light.

The direction of progress, therefore, clearly lay in the production of a colourless, or at least non-staining, desensitiser, and whilst, no doubt, research workers in this country have been experimenting with this end in view, their efforts have not been so successful as those of our late enemies, the Germans. This could scarcely be otherwise; for, whilst our dye manufacturers have been fully occupied in making products which were exclusively manufactured in Germany before the war—products which have been dealt with in bulk and which have been urgently required for our textile industries—the chemists of the latter country have been able to devote their research time to the investigation of the more out-of-the-way properties of hundreds of dyes and intermediates already on their shelves.

The world-renowned photo-dye chemist, Dr. König, of Hochst a/Main, who collaborated with Dr. Lüppo-Cramer in the work on phenosafranine, has continued his investigations and has discovered entirely new classes of products, which are as efficient as phenosafranine as desensitisers, and some of which are colourless. Others, though coloured, have been found to be without staining action on gelatine or on the fingers of the operator; most promising results it must be admitted, but there are at least two other properties which must be possessed by an efficient desensitiser, viz., ready solubility and non-interference with the ordinary course of development. The writer has already called attention to the fact that with certain developers phenosafranine exerts a pronounced retarding action, while with hydroquinone the characteristic pause between pouring on the developer and the appearance of the image vanishes—in fact, hydroquinone

as a developer, either after a preliminary desensitising bath of phenosafranine or as a mixed developer containing phenosafranine, behaves exactly like metol.

By the courtesy of Dr. König the writer has been enabled to test the two products which are at the moment considered the best obtainable. They have been labelled by their discoverer "Pinakryptol" and "Pinakryptol Green," and, whilst the former is a mixture of a colourless with a coloured non-staining substance, the latter is a pure green-coloured substance, almost devoid of affinity for gelatine, skin, etc. The test results are of sufficient interest perhaps to warrant publication, if for no other reason than that they indicate how near to the ideal research is bringing us.

Pinakryptol.

This is a dark greenish-grey powder, the larger proportion of which is only soluble with great difficulty even in 5,000 times its weight of warm water. As it does not appear possible to prepare a stronger solution than 1: 5,000, one must either be able to weigh out exceedingly small quantities or deal with large volumes of solution. One would naturally choose the latter method of working, and so minimise the risk of spoiling sensitive material by reason of flying specks of the dry Pinakryptol. The 1 : 5,000 solution, which is of a turbid grey-green character, can be used either as a preliminary bath—immersing the plate or film therein for not less than one minute in the dark before proceeding to development in a full red or orange light (or by candle light)—or 25 per cent. by volume of the Pinakryptol solution may be added to the usual developing solution, and the first 1½ to 2 minutes of the developing operation be conducted in a "safe" light.

Desensitising Efficiency.—The writer has only tested this desensitiser according to the former method so far, and has found that the reduction of sensitiveness with a Kodak super-speed portrait film is of the order of $\frac{1}{1,100}$; it is, therefore, of somewhere about the same efficiency as phenosafranine. Experiments with a panchromatic emulsion indicate that the Pinakryptol is at least 1⅓ times as efficient as phenosafranine in desensitising for the shorter wave-lengths (blue end of spectrum) and at least 2½ times as efficient as phenosafranine in desensitising for the red end of the spectrum.

Staining Tendency.—The almost complete lack of affinity between the small proportion of green substance which is present in Pinakryptol, and the entire absence of colour from the constituent present in the larger proportion, lead to a finished negative, even on film base, which, after five minutes' washing in running water, is quite free from stain. A marked advantage over phenosafranine is thus evinced. It will be obvious also that Pinakryptol may find application in stand development, there being no objection to prolonged immersion in a bath containing this desensitiser.

Development Effects.—These can be most conveniently stated in a tabular form, and they will therefore be given, along with those evidenced by Pinakryptol Green, at the end of this communication. It is only necessary here to point out that a retardation of development is caused by desensitising with Pinakryptol.

Pinakryptol Green.

This product comes on to the market in small, granular crystals, which exhibit a green appearance by reflected light. It has the characteristic appearance of what are commonly termed "basic" dyes. It is fairly readily soluble in water, and a 1: 500 stock solution of an intense green colour can be conveniently made up and diluted 1 : 10 for use as required.

Desensitising Efficiency.—Used as a preliminary bath 1 : 5,000 for one minute on Kodak super-speed portait film, the sensitiveness was reduced to $\frac{1}{1,500}$, it is thus a more efficient general desensitiser than either phenosafranine or Pinakryptol. Like these products it may also be combined with the developer, in which case five to ten minims of the 1 : 500 solution should be added to every fluid ounce of the developing solution and the development conducted in a safe light during the first minute. The desensitising action of Pinakryptol Green on a panchromatic emulsion is of the same order as that of phenosafranine for blue light, whilst for green, yellow and red light the depression of sensitiveness is so great that no developable image was produced in the tests made by the writer by the action of lights sufficiently strong to give pronounced effects on a phenosafranine-bathed plate.

Staining Tendency.—The colour of the 1 : 5,000 solution of this product is so intense a green that pronounced staining of the gelatine is naturally looked for; whereas, as a matter of fact, there appears to be no staining whatever, the only discoloration which is noticed when the film is removed from the developer is that due to the green solution soaked into the film. It is removed at least as readily as the fixing bath products; ten minutes' washing in running water being ample to give a colourless negative, even on N.C. film base, which is coated both back and front with gelatine. Moreover, dishes are quite unstained by the solution, which in the full red or orange light of the workroom can be most conveniently handled owing to its apparent black colour.

Development Effects.—These will now be expressed in tabular form, including, for reference, the results obtained when a 1 : 5,000 bath of phenosafranine is used as a preliminary desensitising bath. All the tests were made on super-speed portrait film, the exposure to screened electric light being the same for each section of film, which was placed in contact with an Eder-Hecht-Goldberg wedge photometer. The developers were used at a temperature of 65 deg. F., and the control film, which is designated as having been subjected to no desensitising bath, was immersed in water for the same time as the remaining films were immersed in the desensitising solutions previous to development.

Hydroquinone Developer.—

A.—Hydroquinone	1 oz.
Potass. metabisulphite	1 oz.
Potass bromide	1 oz.
Water	...to 40 ozs.
B.—Caustic potash (sticks)	2 ozs.
Water	40 ozs.

Equal volumes A and B are mixed for use.

Desensitising Bath.	Time of Appearance. Secs.	Total Time. Mins.	Total Time. Secs.	Watkins Factor.	Notes.
None ...	30	3	0	6	The four results are practically identical in amount and contrast of image.
1 : 5,000 Phenosafranine .	2	2	0	60	
1 : 5,000 Pinakryptol	12	2	36	13	
1 : 5,000 Pinakryptol Green	2	2	0	60	

Metol Hydroquinone Developer.—

Metol	15 grs.
Hydroquinone	60 grs.
Sodium sulphite (crystals) ...	1½ oz.
Sodium carbonate	1½ oz.
Potass. bromide	4 grs.
Water	...to 40 ozs.

Desensitising Bath.	Time of Appearance. Secs.	Total Time. Mins.	Total Time. Secs.	Watkins Factor.	Notes.

1 : 5,000 Pinakryptol ...	60	4	30	4½	Slightly weak.
1 : 5,000 Pinakryptol Green	20	4	0	12	Normal contrast.

Pyro Developer.—

A.—Sodium sulphite (cryst.) ... ... 16 ozs.
Sodium carbonate (cryst.) ... 16 ozs.
Water ... ... to 80 ozs.

B.—Pyro ... ... 2 ozs.
Potass. metabisulphite ... ... ½ oz.
Water ... ... to 80 ozs.

Mix 1 volume A, 1 volume B, and 2 volumes water for use.

Desensitising Bath.	Time of Appearance. Secs.	Total Time. Mins.	Secs.	Watkins Factor.	Notes.
None ...	25	5	0	12	Normal contrast.
1 : 5,000 Phenosafranine .	12½	2	30	12	Appreciably weak
1 : 5,000 Pinakryptol ...	33	5	0	8½	Appreciably weak
1 : 5,000 Pinakryptol Green	12	2	25	12	Slightly weak; image of greenish colour.

Action on Latent Image.

The action of these desensitisers on the latent image was also investigated, and it was found that there is no destruction whatever caused by either Pinakryptol or Pinakryptol Green, even if prolonged action of the 1 : 5,000 bath is allowed. The very pronounced retardation of development caused by Pinakryptol might lead one erroneously to conclude that some destruction of the latent image is caused by this desensitiser. As a matter of fact, the "threshold" values of two negatives—one of which was developed after a given exposure without a preliminary desensitising bath and the other developed after a similar exposure, followed by two minutes' treatment with a 1 :5,000 Pinakryptol bath—are identical. There need be no misgivings, therefore, on the question of interference with the "speed" of a given plate or film by desensitisation with either of these new products. If Pinakryptol is used, it is only necessary to prolong development by something like 25 per cent. to 30 per cent. in order to obtain a negative of normal contrast. The writer, however, prefers to use Pinakryptol Green. But this is a free country, and every worker is at liberty to make his own experiments and choose for himself, for the products may be obtained from Messrs. A. Connell and Co., of Bevis Marks, London, E.C.

RAYMOND E. CROWTHER.

THE PHOTOGRAPHY OF WATERMARKS IN PAPER

[Among the subjects of exceptional difficulty which have sometimes to be undertaken by commercial photographers, and particularly by those doing work for legal purposes, are watermarks in paper, the reproduction of which is often of importance in determining the age or origin of a document. In the following article in the "Zeitschrift für wissenschaftliche photographie," Dr. O. Mente deals with this branch of work, and describes two new and ingenious methods for overcoming the great difficulties in obtaining clear reproductions of the watermarks in the case of documents which bear writing on both sides.]

In the case of documents, the paper of which has a prominent watermark, a reproduction of the latter may often be obtained of sufficient distinctness, even when there is writing on both sides, simply by making a contact print on P.O.P. or development paper. Especially by choosing a development paper of character suitable to the original which is to be copied, and also by controlling the development, comparatively good copies may be obtained in which the writing on each side of the document is little in evidence.

For example, by giving such a short exposure that the light penetrates only through the thinnest portions, namely, the watermark, of the paper, scarcely any developable effect is produced in the other parts, and a most satisfactory result may be obtained. A further means towards improving the result consists in stopping development at the moment when the watermark has been brought up, whilst other parts of the image have scarcely begun to develop. Nevertheless, by such methods as these the result is only a moderately strong image of the watermark, more or less broken up by the writing on the document. Inasmuch as many watermarks do not include minute details, these ordinary methods often suffice for recognition and reproduction of their design.

More difficult subjects of this kind are, however, often encountered, for dealing with which the writer has devised other methods which have proved satisfactory in use. Various forms of procedure may be followed. For example, the original may be mounted between two glass plates and a negative made by transmitted light, and a weak positive transparency from this latter. This transparency is then brought into register with the negative, and the combination of the two is used for contact printing or enlarging. The final result by this method is, however, not appreciably better than that by those already mentioned.

Another method is to make the negative, again by transmitted light, on paper of card thickness, or, better, on lantern emulsion coated on opal. The positive transparency from this negative is bleached with mercury bichloride or solution of iodine in potassium iodide and brought into register with the negative. The result then is that the dark lines of the writing are greatly subdued when viewing the combination (through the bleached positive transparency) by reflected light, whilst the details of the watermark come out fairly well with skilful use of the process.

But the above methods require a considerable dexterity and judgment. Moreover, it is almost necessary to employ the wet collodion process on account of the facility with which negatives and transparencies of the required character are obtained by its means. And when all has been done the result frequently falls short of expectations. It therefore seemed advisable to seek a process which could be carried out with greater ease and certainty and was applicable to those cases in which the design of the watermark was closely entangled with the writing on one or both sides of the paper.

After many experiments the writer devised a method dependent upon the lesser thickness of the paper in those parts which represent the watermark. He first experimented with a method of taking an actual cast of the watermark in plaster of Paris. A thin film of plaster of Paris was coated on a flat glass plate on which the original was laid. More plaster of Paris was applied until a mass of fair thickness was obtained and the whole was then put to dry in a warm place. As soon as dry, preferably by means of a hot plate,

the original is readily detached from the plaster of Paris, and often comes away of itself. The relief which is left may be photographed in strong side light, or may be strengthened for photographing by coating it with black lithographic ink and polishing the whole surface with the ball of the hand.

It will be understood that such a process as this does not yield very satisfactory results with watermarks in weak relief, and, moreover, it suffers from the drawback that writing which has been done with a hard pencil on a comparatively soft paper is reproduced by the casting method just as though it formed part of the watermark.

A much more more satisfactory method, which works perfectly for the most delicate watermarks, even when accompanied by heavy writing, has been worked out by the writer in conjunction with Dr. H. Francke, and depends on the diffusion of gas through parts of the paper of different thickness. It is, of course, necessary that the ink which forms the writing should not obstruct the diffusion of the gas, otherwise the process could not be expected to yield better results than those by ordinary printing. In practice it was found by some preliminary rough experiments that the ink does not impede the diffusion of the gas (ammonia) in the slightest, and hence it was necessary only to devise the most advisable form of the process. After many fruitless experiments the following method of operation was devised and was found to be extremely successful:—A sheet of ordinary development paper is given a short general exposure (to fog it slightly), developed, fixed, washed, bleached in mercury bichloride, and dried. This "sensitive" paper is used for recording the action of the ammonia gas which passes in different degrees through the document. In order to avoid treating the original with ammonia solution a piece of flat, unglazed porcelain is soaked in strong ammonia, removed from the solution and allowed to become dry on the surface by short exposure to the air. The original is laid on this plate and the bleached sheet of development paper laid on it. The ammonia, discharged evenly from the area of the impregnated plate, then passes differentially through the original and darkens the white mercury compound existing over the area of the paper. The clear image of the watermark which is produced in this way may be readily strengthened in pencil.

O. MENTE.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[REGULARLY each year the Society of Chemical Industry renders a valuable service to those connected with the manufacturing and scientific sides of photography by including in its "Annual Reports" one on photographic materials and processes. The report for the year 1921 is written by Mr. F. F. Renwick, F.I.C., whose large share in photographic research qualifies him exceptionally as a recorder of recent investigations in the technical improvement of processes of making negatives and positive prints, orthochromatics and colour photography, cinematography, and photo-mechanical processes. The report exhibits the work which obtained publication last year in its relation to previous knowledge better than any other communication which comes before the photographic industry, for which reason we endeavour to find a place for it in our pages. As regards the references to original sources of publication, it should be explained that the contraction "J" denotes the fortnightly "Journal" of the Society of Chemical Industry, in which are published abstracts of the chief papers dealing with the chemical side of practical, scientific, or industrial photography.]

(*Continued from p.* 342.)

An interesting short discussion of the various systems of colour cinematography theoretically possible, which contains some very decided expressions of opinion concerning them, is to be found in an article recently published by A. Gleichmar.[16] He rules out as unworthy of consideration all two-colour systems and states clearly but briefly the demerits and inherent difficulties of each of the methods available to experiment. An article by C. E. K. Mees in "The Photo Miniature" for July, 1921, also contains interesting expressions of opinion on the subject.

The only process of colour cinematography to come on the British market during the year is the American one "Prizma," made under W. V. D. Kelley's Patents.[17] It is a two-colour process in which the picture is composed of juxtaposed microscopic areas of orange-red and blue-green, made by dye-toning on either side of a double-coated film. A short film based on a three-colour subtractive process by S. M. de Procoudine-Gorsky[18] was exhibited privately in London last spring.

In connection with processes of staining up the positive colour records, considerable attention is being devoted to the dye-absorptive properties of the silver halides and metallic ferrocyanides,[19] while a novel property of the developed silver image forms the basis of a patent by J. H. Christensen,[20] who finds that in the presence of suitable reducing agents (*e.g.*, amidol or hydrosulphites) certain dyes are readily reduced to their leuco bases where the silver image occurs. An interesting reaction of a similar kind is described by J. I. Crabtree[21] who finds that even an ordinary acid "hypo" fixing bath can function as the reducing agent.

Colour Photography.

In a chapter of J. Plotnikow's recently published book on "Photochemistry"[22] appears the only important new suggestion of a possible method of recording colour photographically. He points out that if dyes could be made which were "fast" to the acid constituents of the atmosphere and to light except in the presence of a colourless catalytic agent, in the presence of which they change, on exposure, to stable colourless products, removal of the catalyst after printing would yield a permanent coloured image. No such combinations of dye and catalyst are, however, known at present.

Apart from this suggestion no new principle appears to have been evolved, and most of the published papers and patents are concerned either with means of overcoming well-known mechanical difficulties, or refer to special toning or dyeing operations in which one or other of the known properties of selectively hardened gelatin, or of the silver image or an insoluble salt formed from it, is employed as medium for the colour.[23]

There can now be little doubt that no process involving the use of more than one plate for negative making is likely to attract the general public. This part of the problem may be said to have been solved by such screen-plate processes as the Autochrome and Paget colour processes. They remain, however, comparatively little used, largely owing to the absence of a simple method of reproducing them in the form of coloured prints on paper. Here again it is probably safe to hazard the opinion that any system involving the making of a colour analysis of the original and a separate printing on paper from each of the three negatives so

obtained would never achieve popularity. Hence all methods based on the superposition of dyed reliefs or on the transfer of dyes to paper to form the print by imbibition from three separate stained-up copies must give way to any successful method of producing the coloured paper print from a single printing plate. An interesting historical survey including some of the former processes is contained in two recent articles by E. J. Wall,[24] while in connection with the possibility of successfully reproducing screen-plate transparencies on paper from a single printing plate the patent of O. Fielitz[25] is worthy of attention.

Colour Sensitisers and Desensitisers.

While the photographic industry shares with most others the need, for tinctorial purposes, of a range of dyes which are fast to light and various chemical reagents, and which are absorbed by certain materials and not by others, it is peculiar in requiring dyes having the power to modify the normal blue-violet sensitiveness of the silver halides by conferring upon them a high degree of sensitiveness to other regions of the spectrum. Some are required to sensitise over a quite limited range of wave-lengths, others for as large a range as possible, and all are desired to operate without depressing the white-light sensitiveness of the emulsion or inducing chemical fog or other defect. The discovery and study of sensitising dyes is an almost limitless and singularly attractive field of investigation which in recent years has received considerable attention in this country in France, and the United States, instead of being left almost entirely to German chemists, as had been the case for some years before the war.

Two new methods of preparing plates highly sensitive in the ultra-violet have been described by J. Duclaux and P. Jeantet.[26] In one case the surface of an ordinary gelatino-bromide plate is coated, before exposure, with a thin film of an oil or other liquid which does not penetrate the gelatine but which fluoresces strongly in ultra-violet light. After exposure this liquid is washed off in a suitable solvent before development is proceeded with.

According to the second method, an ordinary dry plate is treated in a horizontal position with sulphuric acid of sufficient strength to dissolve the gelatine. The silver salts settle on to the glass and are washed free from gelatine and acid in a sluggish stream of water, dried, and finally protected by a thin coating of collodion before exposure. Such plates are stated to be highly sensitive to ultra-violet radiation even beyond 1900 A.U.

It is apt to be overlooked that even the fastest modern dry plates do not fully utilise the normal sensitiveness of silver bromide because of the high opacity of gelatine and of our glass lenses to short-wave ultra-violet light. With such plates as those described above it would be very interesting to investigate the possibilities of utilising as sensitisers colourless substances having absorption bands in the ultra-violet region.

Even the most satisfactory colour sensitisers known are far from enabling us to utilise the incident light-energy in other regions of the spectrum so efficiently as the undyed plate utilises the blue-violet. As a matter of practical experience it has been found extremely difficult to increase the total sensitiveness to bright daylight of a rapid dry plate by colour-sensitising it, the added sensitiveness to longer wave-lengths being always accompanied by a fall in blue-sensitiveness. That this result is not due to any direct antagonism between lights of different colours when operating simultaneously is negatived, not only by giving equal exposures in a spectograph to plates of the same batch, both undyed and dyed, and comparing the effects in the blue, but by a recent communication of F. C. Toy,[27] who finds the effects of differently-coloured lights acting together to be simply additive. At present it remains obscure why we are unable enormously to increase the sensitiveness to white light of fast emulsions by colour-sensitising them. With very slow, fine-grained emulsions it is quite easy to accomplish this, as most practical emulsion makers have long known, but the point has been emphasised very usefully, and amply illustrated, in papers, by Lüppo-Cramer[28] during the past year.

For some time two or three dyes have been known (Pinachrome Violet, Sensitol Violet) which operate without reducing, if they do not enhance, the total sensitiveness of rapid plates to white light, but they are very prone to cause fog and are otherwise difficult to handle. During the year a new and powerful green-sensitiser, said to be a basic dye of an entirely new class, has been put on the market by the firm of Meister, Lucius, u. Brüning under the name Pinaflavol. It confers sensitiveness throughout the green extending to the D (sodium) lines and shows no depression of sensitiveness in the blue-green as do dyes of the eosine class. Like those already mentioned, it has the unusual property of enhancing rather than diminishing the total sensitiveness of the plate, but unfortunately it also readily gives rise to chemical fog and shortens the useful life of plates treated with it.[29] Another dye of the same type has been examined and reported on by Lüppo-Cramer under the designation P2 showing these qualities in a still greater degree. Incidentally he makes several interesting observations on the different effects of chemical and physical development in such cases, no chemical fog being obtained by the latter method of development, and a greater relative increase of sensitiveness being found. Other papers by the same author[30] dealing with the colour-sensitising of silver iodide contain a number of curious and interesting observations.

Patents have been granted to E. Q. Adams and H. L. Haller for sensitising dyes of the dicyanine class produced by the action of alcoholic solutions of strong bases upon the alkyl iodides of lepidine.[31] Miss F. M. Hamer has prepared and systematically studied a large group of isocyanine dyestuffs containing the amino, acetylamino, or cinnamoylamino groups in all practicable positions in the molecule and has drawn conclusions concerning the influence of these groups and their positions in the molecule on sensitising properties.[32]

In a paper by W. König and O. Treichel[33] dealing with the constitution of the cyanines and isocyanines the authors abandon König's earlier view that in preparing these dyes one of the quinoline rings has suffered fission of the pyridine ring, the reason being that compounds of this type, when prepared, failed to show the characteristics of the isocyanines. The paper contains, besides, descriptions of a series of condensation products of dimetylaminobenzaldehyde, and dimethylaminocinnamaldehyde with α and γ methyl cycloammonium salts, which it would be interesting to examine for sensitising properties in view of Mills and Evans' negative result with o-aminocinnamylidenequinaldine (see *Ann. Repts.*, *6*, 116).

Confirmation of the writer's observation of red sensitiveness conferred by the action of soluble iodides upon silver bromide emulsions is forthcoming in a paper by R. B. Archey[34] and in one by S. E. Sheppard, who, however, finds the effect not to be common to all emulsions.

A very considerable amount of attention has been devoted to the study of desensitising materials which have now found a useful field of application in practical photography. Prior to Lüppo-Cramer's discovery of the utility of the safranine dyes as desensitisers which do not impair the latent image, this class of substances was regarded simply as an unmitigated nuisance to the manufacturers and users of photosensitive materials since they are of fairly widespread occurrence and readily give rise to insensitive spots and markings on their products. Lumière and Seyewetz[35] have studied a large range of dyes and other materials for desensitising properties and find Aurantia (ammonium salt) sufficiently powerful for desensitising Autochrome plates and preferable to phenosafranine on the ground of the greater ease of removing the dye afterwards. Lüppo-Cramer[36] has actively pursued the subject and concludes that desensitisers act as mild oxidising agents in preventing the formation of a latent image. As might have been expected, in view of the known depressant action of many colour-sensitisers, it has been found that phenosafranine and some other desensitisers can exert a colour-sensitising influence.[37]

Photographic Developers and Development.

There have been no important additions to the already large assortment of available developing agents during the year. Patents have been granted to E. Kolshorn[38] for derivatives of *p*-aminophenol and its O alkyl ethers, to A. S. McDaniel and A. H. Nietz[39] for the use of diaminophenolsulphonic acid in alkaline solution, and to J. Hauff u. Co.[40] for *o*- and *p*-amino and diaminophenol and cresolsulphonic acids in alkaline solution.

W. Ermen[41] has made some interesting comparisons of the relative rates of exhaustion of a number of developers in equal concentrations, the results showing clearly that the price per ounce is a very imperfect criterion of the real cost of a developing agent when it is used economically and in quantity. In a series of articles B. T. J. Glover[42] discusses the application of the Watkins factorial method of the development of plates and papers; one of the most important points emphasised is that for bromide papers there is a certain range of correct exposures within which identical prints are obtainable by compensatory alterations in the length of development.

The important question of preserving developing solutions from atmospheric oxidation continues to receive attention, the most interesting contributions being M. J. Desalme's method[43] of preserving amidol by means of a complex stannous tartrate solution, and L. J. Bunel's method by means of lactic acid,[44] which are both fairly effective. Unfortunately they do not obviate the indelible black stain which amidol imparts to the fingernails on prolonged working with this developer.

To Lüppo-Cramer[45] are due some further interesting observations on the increased rapidity of action of quinol (hydroquinone) developers in the presence of traces of phenosafranine. He recommends this mixture as a cheap developer of the rapid class and ascribes the previously observed similar effect of mere dilution in the case of amidol and several other developing agents to the liberation of the free base by hydrolysis and its absorption by the silver halide.

The subject of chemical fog, its relation to sensitiveness, and the causes which give rise to it, is one of very great practical importance and theoretical interest. No researches specifically devoted to this subject have appeared, but incidentally a number of new circumstances in which it arises have been observed by Lüppo-Cramer.[46] The frequently expressed opinion that chemical fog is due to partial or to excessive chemical reduction of the silver halide by reducing products, formed during the hydrolysis of gelatine which occurs during ripening, may be, and probably is, one possible cause but certainly does not cover more than a small proportion of all cases. For instance, the large granules or small clots of a badly-made (granular) emulsion are always rapidly reduced in development, even in a slow almost unripened emulsion, while the writer has experience of a bromochloride emulsion boiling method) which was prone to black fog when ripened by standing for 5 minutes in boiling water, but which gave no fog if the boiling treatment was increased to 8 or 9 minutes. There seems to be much to support the idea that electrically neutral particles of silver halide are instantly reducible by a photographic developer whether embedded in a colloid vehicle or not. There are so many known ways of inducing chemical fog that it is now highly desirable to submit them to a thorough study in the hope that their ultimate causes may be reduced to a few and based on fundamental principles.

Photomechanical Processes.

In this direction no striking new development appears to have taken place apart from the "Photosculpture" process due to H. M. Edmunds already referred to, which, properly speaking, falls under this heading.

The year has been chiefly notable for the many attempts that have been made by lithographic firms to apply the three-colour process to lithography. The chief difficulty encountered has been the necessary retouching, which cannot be so readily carried out on lithographic zinc plates as it can on half-tone blocks. One method of overcoming this difficulty has been provisionally protected by A. E. Bawtree. It consists of applying to each patch of colour in the original a piece of suitably-coloured cellophane; this alters the colours of the original by an amount which corrects the change in reproduction, so that the colours as reproduced should be correct.

The old idea of impressing a grain, regular or irregular, upon a collotype plate instead of using the natural reticulation of the film, has been revived by A. R. Trist, who is using for this purpose a regular screen with fine lines. So far as this work has gone, it indicates that there is a possibility of obtaining collotype plates that are easily inked, and will give longer runs in the printing machines.

A recent paper by H. M. Cartwright[47] on the rendering of tone values by rotary photogravure is a welcome indication that modern methods of dealing with tone reproduction problems are being applied to photomechanical processes. Such studies will surely lead to improvements in technique based on accurate knowledge in a field where, hitherto, empiricism has reigned supreme.

Radiography.

The formation[48] of The Society of Radiographers, designed to include all qualified non-medical assistants who are engaged in the practical application of X-rays under the direction of Medical Officers, is a noteworthy step. It is to be expected that one useful result of this new departure will be an all-round improvement in the conditions under which such assistants have to work and a higher percentage of first-class skiagrams.

In some X-ray departments, even in quite important institutions, there has been only a very scanty appreciation of the importance of a thorough acquaintance with photographic technique, and the advantages of well-equipped dark-rooms.

An interesting novelty in X-ray-sensitive materials due to L. A. Levy, A. L. Landau, and T. T. Baker[49] has been put on the market. It consists of a silver gelatino-bromide plate having a hardened emulsion film upon which is coated another and a readily-soluble gelatine layer carrying fluorescent calcium tungstate. After exposure, stated to range from one-fifth to one thirty-fifth of that required for ordinary X-ray plates according to the hardness of the radiation employed, the upper film is washed away in hot water and the lower film of hardened emulsion is developed. Any such method, involving the coating and subsequent removal of a fluorescent layer in intimate contact with the sensitive emulsion, necessarily has drawbacks and it is to be hoped that some water-soluble highly-fluorescent substance which can be incorporated harmlessly with the emulsion will ultimately be found, though a large amount of investigation has, so far, failed to disclose one which is both highly active and not injurious either to the sensitiveness or the stability of the silver halides.

It has been found unsafe to produce X-ray motion pictures by photographing a fluorescent screen image with the aid of a cinema camera,[50] the radiation necessary being so intense as to endanger the patient.

A valuable contribution to the technique of radiography is a paper by R. B. Wilsey,[51] on the intensity of scattered X-rays in radiography, in which he shows what a small proportion of the total radiation reaching the plate consists of useful image-forming rays when thick subjects are being radiographed or large diaphragms used.

The same investigator[52] has employed homogeneous X-rays to determine the structure of the crystal lattice in precipitated flocculent silver chloride, bromide, and iodide, and shows that these apparently amorphous precipitates are definitely crystalline in their ultimate structure and belong to the cubic system. He proposes to proceed to the examination of the crystalline grains of photographic emulsions by similar methods. The results will be awaited with great interest since such studies will probably throw light on the question of the distribution of the iodine atoms in the crystals of a silver iodobromide emulsion. There has been a strong inclination to assume, without any sort of proof, that such crystals are homogeneous solid solutions of the two halides, but

some observations of the writer's on the co-precipitation of these salts seem to make this supposition doubtful (see later).

Photographic Emulsions.

Experimental work on emulsion making is but rarely published. The past year is exceptional in that a few such papers have appeared giving the conclusions which have been drawn from the results, but in each case important experimental details are purposely omitted. P. Knoche[52] has unsuccessfully sought to gain some advantage by delaying the formation of the silver halide by substituting brominated organic compounds for the usual alkali bromides. C. A. Schleussner and H. Beck[54] publish the results of an attempt to elucidate the effect of varying the proportion of iodide in silver iodobromide emulsions. They find an optimum steepness of gradation and sensitiveness for a certain iodide percentage (which, however, changes with the conditions under which the emulsion is mixed) and a maximum X-ray sensitiveness in pure bromide emulsions; other points are also discussed. Their division of such emulsions into three classes is useful, but the assumption that emulsions formed by the addition of silver solutions to the mixed halides leads to the formation of a double compound of AgBr and AgI during the emulsification, and that this method therefore guarantees uniformity of composition of the precipitated grains, is in the writer's opinion not justifiable. It is easy to show that (in the presence of ammonia) the silver iodide (or a more insoluble iodide-bromide complex) is always precipitated before the bulk of the bromide, and there is apparently no reason therefore why the iodide should be uniformly distributed in any crystal or why different grains should not vary considerably in the proportions of silver bromide to iodide composing them in the early stages of ripening and very possibly even in the finished emulsion.

W. T. Wilkinson[56] has recently advocated the use of a mixture of bromide and chloride instead of the usual iodising solution in the wet collodion process, which still occupies a strong position in line and half-tone work.

There have been several important papers and discussions concerning the relation between sensitiveness and grain size of silver halide emulsions. Mees[55] has abandoned his earlier assumption of a direct connection between grain size and sensitiveness, a conclusion shown to be inevitable by the work of Svedberg (mentioned in last year's report, since published in English[57] with interesting extensions to the action of α- and β-particles) and confirmed in some emulsion-making experiments by the writer[58] and by A. P. H. Trivelli and S. E. Sheppard.[59] Svedberg's work has been recently extended by F. C. Toy,[60] who showed that even grains of identical area, shape, and thickness may vary greatly in sensitivity. J. Brooksbank[61] has shown that in the rate and degree of visible darkening of the grains in light there is a similar want of relation to size and shape. We are therefore compelled to assume differences in the molecular construction and/or the chemical composition of the crystals to be the prime factors determining the sensitivity of the individual grains, though it must still be admitted that to attain a given sensitiveness it seems from practical experience necessary that a certain minimum average size of grain should be exceeded.

Practically nothing is known at present except in a purely empirical fashion about the effects of the conditions of precipitation on the grain size of silver halide emulsions. A few experiments bearing on the subject are to be found in Trivelli and Sheppard's monograph already mentioned, but inasmuch as the results have a considerable commercial value it is unlikely that any detailed studies will be published by those engaged in the industry.

Recent papers by von Weimarn, S. Odén, and others[62] are, however, sufficient to show the extreme difficulty of such researches even in such relatively simple cases as barium sulphate precipitates. Svedberg's recently published little book on "The Formation of Colloids" contains a brief account of some of their results and a valuable bibliography. The fullest development of the art of emulsion making is likely to depend on the results of such studies, and therefore men of the highest scientific qualifications will undoubtedly be required in the industry in considerable numbers, and will need very well-equipped laboratories.

An interesting mathematical study by L. Silberstein[63] demonstrates how, as a consequence of the drying of the gelatine film, the great majority of the silver bromide grains in a dry plate lie approximately parallel to the surface.

Photo-Mechanical Notes.

Collotype Plates from Negatives by Mercury Intensification.

A recent patent specification, No. 162,640, of M. de' Spetati, 78, Corso Stupinigi, Turin, adds another to the many variations of the collotype process which have been proposed. A negative, before sensitising with bichromate and before exposure to light, is submitted to a treatment, the effect of which is that the silver incorporated in the gelatine is in part replaced by another body with larger grains, which gives place to a strong hardening of the layer of gelatine; this allows of obtaining very resistant collotype plates which can be inked very easily.

With this object use is made of treatment by bichloride of mercury and ammonia, as in intensification. By such intensification greater opacity is given to the dark portions (corresponding to the light portions of the positive), the thickness of all portions which originally contained metallic silver is increased and a larger capacity for absorbing moisture and for rejecting greasy ink is given to the light portions and to the half tones.

After the treatment with mercuric chloride and ammonia, the negative is washed over with water and is directly immersed in a sensitising bath of 2 per cent. of bichromate (preferably of ammonia), in which it is kept for about five minutes with continuous stirring of the tank.

The negative is then dried in a dry, dark place or in a place lighted with a red light, and protected from any dust.

The negative is afterwards exposed in a frame to daylight for 16 to 60 minutes, according to the intensity of the light, the negative being arranged in the frame in such a manner that the layer of sensitised gelatine containing the negative image is kept in contact with a sheet of white paper, while the back of the negative is kept in contact with the glass.

The surface intended to form the plate used for ink printing is in this manner sensitised from the back, because the light reaches more or less the surface of the bichromated sensitised layer according to the opacity of the negative image, and the chromatisation takes place in a graduated manner, thus ensuring any shade of half-tints and sparing the light portions. The negative is washed in running water or in five or six waters for freeing it entirely from the soluble bichromate, and is afterwards carefully wiped dry, for example, with a sponge. It kept in a dry place and protected from the air, it may be indefinitely preserved, and when it is desired to proceed with the ink printing, it is sufficient to immerse it for at least one hour, in a solution containing 200 ccs. of water, 300 ccs. of glycerine of good quality, and three or four drops of ammonia. This bath is kept at a temperature between 35 and 80 deg. C., according to the nature of the work.

The plate is wiped over dry and mounted on a suitable support, and may then be utilised in any printing machinery provided with good inking.

The zones of the surface of the plate upon which the light has acted, become more or less unpolished, according as they have been subjected more or less to the action of the light, and they retain more or less the ink according as they are more or less unpolished; the zones which have not been subjected to the action of the light are, on the contrary, more or less polished and more or less saturated with moisture, and they reject greasy ink owing to the absorbed moisture.

The images obtained by the printing of plates prepared according to the present process are stated to be of a fineness equal to that given by photography owing to the absence of any visible grain.

Celluloid Collotype Printing Plates.

The use of a celluloid support for the layer of bichromated gelatine in the collotype process is the subject of a patent, No. 170,545, granted to M. de Sperati, 78, Corso Stupinigi, Turin. The celluloid is given a substratum consisting of a mixture of gelatine with a solvent of the celluloid for the purpose of obtaining a complete adherence of the subsequent layer of gelatine to the celluloid sheet.

The process is carried out by spreading the mixture of gelatine and celluloid solvent upon the surface of the celluloid by means of an emulsifying machine of any known type.

After this a 10 per cent. emulsion of gelatine of medium hardness is prepared and to this emulsion a suitable antiseptic is added, such as carbolic acid. The emulsion is spread hot by means of an emulsioning machine at a temperature of about 50 deg. C., and at the rate of about 5 ccs. per square decimetre upon the celluloid which has been treated in the manner which has been indicated and afterwards dried in a ventilated place at a temperature of about 30 to 35 deg. C.

The celluloid thus treated is cut to the desired size and kept protected from dust and moisture; it keeps indefinitely, and may be sold in this form in which it may be used for printing after being simply subjected to a sensitising bichromate bath.

In order to prepare the collotype plate, the sheets of celluloid are sensitised by immersing them in a solution of potassium bichromate at 3 to 4 per cent. Good results are obtained by adopting the following composition:—

Distilled water	100	ccs.
Potass bichromate	3	gms.
Ammonia 22 Bé	3	ccs.

After treatment in this bath, which should last from three to five minutes, the sensitised films are dried in darkness at a temperature of about 30 deg. C. The exposure of the bichromated layer to the light is effected underneath an ordinary photographic negative. The exposure may be effected as usual by placing the bichromated gelatine against the gelatine of the negative after having laterally reversed the negative image, and in this case very defined or sharp images are obtained; or the exposure may be effected through the back, this being permitted by the support of celluloid being even, translucent and thin, and in this case the lateral inversion of the negative image is done away with.

By operating in the second manner, very good collotype reproductions are obtained having peculiar soft shades.

After exposure a thorough washing with water eliminates the soluble bichromate, the plates are treated in a bath of water and glycerine, and the inking and printing are effected in the ordinary manner.

The following patent has been applied for:—

PRINTING PROCESSES.—No. 13,456. Photo-mechanical printing processes. A. R. Trist

FORTHCOMING EXHIBITIONS.

June 1 to 30.—Royal Photographic Society. Prints by Pirie Macdonald, of New York. Open daily from 11 to 5 p.m., 35, Russell Square, London, W.C.1.

August 26 to September 9.—Toronto Camera Club. Latest date for entries, July 22. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43 Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for Entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, May 29 to June 2:—

PLATES.—No 14,997. Manufacture of photographic plates and films. H. E. Coley.

FOCUSSING DEVICE.—No. 15,144. Focus controller for photographic copying cameras and enlargers. C. Lane.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

VERTICAL SELF-FOCUSSING ENLARGERS.—No. 156,224 (March 28, 1916). The apparatus comprises a pivoted arm or bracket forming a support for the camera and so arranged that as the camera is moved towards or away from an easel or projection screen its axis is kept normal to the plane of the screen, operative mechanism being provided between the arm and the camera or lens whereby any movement of the support relatively to the easel automatically effects the focussing. Preferably a parallel linkage is employed to support the camera, the camera itself being mounted upon an adjustable member on the support and provided with a rack engaging mechanism connected to one of the pivoted links adapted

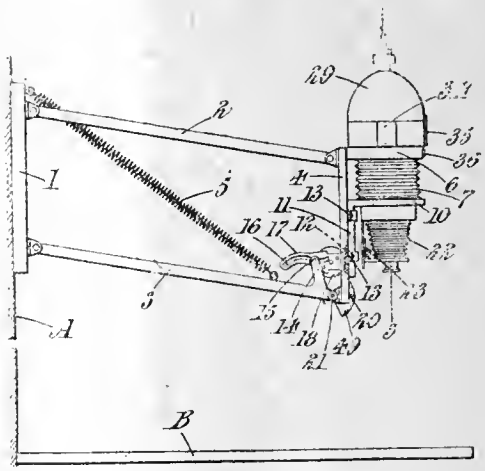

Fig. 1.

to co-operate with the rack so as to maintain the required focus when the support is moved about the arm, clamping mechanism being also conveniently provided to prevent relative movement between the arm and support when the required focus is being secured. The pivoted arms are preferably counterweighted or spring controlled to balance the weight of the camera and its support and a source of light, for instance an electric incandescent lamp, is secured to the rear end of the camera or to a bellows extension thereof adapted to participate in the movement of the camera support, spaced translucent plates being preferably interposed between the source of light and the negative whereby the light is properly diffused and ventilation to prevent overheating is secured.

In the construction illustrated in figs. 1 to 5, A represents the side wall of a room or any other rigid vertical support, and B the top of a table or other horizontal support for the printing paper constituting the easel or projection screen. Secured to the

wall is a block 1 to which are pivoted swinging arms 2 and 3 having their outer ends connected to a camera support 4 counterbalanced by a spring 5 so that the whole structure constitutes a parallel linkage which can easily be moved up and down into any desired position, the support 4 always being kept normal to the plane of the table B.

The block 1 is mounted upon the wall at a suitable distance above the table B, depending upon the focal length of the camera employed. Rigidly secured to the support 4 is a frame 6 carrying a bellows 7 having at its opposite end a frame 9 (fig. 3) secured to a sliding carrier comprising arms 10 and a bar 11 carrying a rack 12. The bar 11 is mounted to slide in guides 13 on the support 4.

On the lower arm 3 of the parallel linkage is an upwardly projecting lever 14 having rigidly secured thereto a pin 15 engaging a cam slot 16 on an arm 17 secured to a toothed quadrant or pinion 18 meshing with the rack 12. The pinion 18 is mounted to rotate in a bracket 19 carried by the support 4 and a clamping

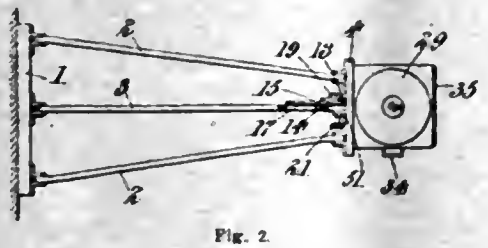

Fig. 2.

screw 21 is provided by means of which the arm 3 and support 4 are held against relative movement when the desired point of adjustment is reached. The camera 22, which may be of any known type, is shown as being provided with the ordinary focussing arrangement 23 and is secured to the frame 9 by means of clamps such as 24 (fig. 3), which may be of any suitable construction. The frame 6 is provided with guides 25 adapted to receive a plate holder 26 flanged to receive the negative 27.

Secured to the frame 6 is a hood 29 provided at its upper end with an electric incandescent lamp 30, and between this source of light and the negative are preferably mounted a series of ground-glass plates 31 supported in suitable guides or carriers 32. As shown, these carriers are spaced so that a current of cool air from outside may pass between them, this air entering through a

Fig. 4.

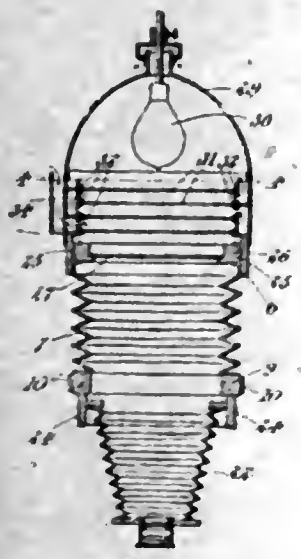

Fig. 3.

Fig. 5.

passage 34 and escaping through an opening in the top of the hood as indicated by the arrows. The slides are introduced through doors 35, 36 (fig. 1).

Forming an extension of the free end of the arm 3 is a scale 40 over which moves a pointer 20 connected to the support 4, this scale being graduated to indicate the degree of enlargement which is being obtained.

The operation of the apparatus is as follows: A negative of the picture to be enlarged is inserted into the apparatus and the light turned on. The focussing screw 23 of the camera is then adjusted to bring the image into focus on the surface B. The camera support 4 is then moved up and down so that the image is projected on to the surface B, this movement changing the relative position of the arm 3 and support 4 and as the pin 15 moves in the slot 16 the pinion 18 is rotated, adjusting the rack 12 to a corresponding extent and thus moving the camera supporting frame 10. The slot 16 is so designed that the distance through which the camera lens is moved will be that required to keep the projected image always in focus, in the particular instance illustrated the curvature of the cam being adapted for a lens having a focal length of five inches.

The operator can thus readily determine with the projected image before him on the surface B just what degree of enlargement is desired or what portions of the enlarged image he may wish to print because the image always remains in focus whatever the degree of enlargement.

Not only does the spring 5 enable the device as a whole to be readily moved, but the pivoted links enable the whole apparatus to be swung against the wall or other support A so that the apparatus is easily disposed of when not in use.

If the supporting device is to be used without an automatic adjustment a pinion 18¹, such as that illustrated in fig. 7, operated

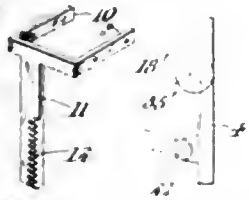

Fig. 6.

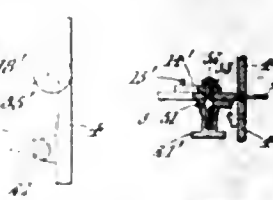

Fig. 7.

Fig. 8.

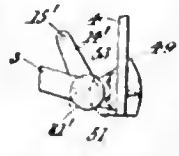

Fig. 9.

by means of a hand wheel 35¹ may be employed, such an arrangement being useful where the camera has no focussing arrangement of its own.

Further, as shown in figs. 8 and 9 the pin-carrying lever actuating the focussing rack may be made adjustable. In that case instead of the arm 14 being rigidly secured to the link 3 an adjustable arm 14¹ having a pin 15¹ is connected to the arm 3 by means of a screw-threaded bolt 52. This bolt is carried in a bracket 51 so as to rotate freely therein, the ends of the bolt being respectively provided with a clamping screw 21¹ and a locking screw 53 to lock the lever 14¹ in the position of adjustment relatively to the arm 3. When the arm is formed adjustable for lenses of different focal lengths, interchangeable slotted arms 17 will be provided having differently curved cam slots necessitating a different setting of the pin 15.—Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, assignees of Roy Samuel Hopkins, 1221½, Market Street, Parkersburg, W. Va., United States.

Dismissing Commercial Travellers.—At the recent Photographic Fair the question of commercial travellers' notices was hotly debated by some parties concerned. Although (writes a correspondent) the particular case referred to has not been the subject of a legal action a similar case was fought a few days ago in the City of London Court. A commercial traveller sued a City firm of manufacturers for £90 damages for wrongful dismissal. Plaintiff was a commercial traveller at £7 a week and commission, and after working for three months he was dismissed with a week's notice. He claimed that there was a universal custom that commercial travellers were entitled to three months' notice, and made his claim accordingly. The defendants said the plaintiff was engaged for three months on trial, but that in any event he was only entitled to a week's notice, which was given him, and that travellers were not entitled to three months' notice. The judge held that the plaintiff was not engaged on trial, and that commercial travellers in the City, he cared not what trade they belonged to, could not be dismissed on a week's notice, simply because they were paid their salary weekly. In his view, if there was not a universal custom, he held that a reasonable notice for a commercial traveller was three months, and therefore he gave judgment for the plaintiff for £84 and costs, stating that he would facilitate an appeal if the defendants so desired, in order that the matter might be settled once and for all.

New Apparatus.

Heatrae Electric Developer Heaters. Made by Electric Fires, Ltd., King Street, Norwich.

Some months ago we published a short note describing an electrical heater of tubular form which had been introduced by a French manufacturer for the warming of photographic developing and other solutions, and for the rapid dissolution of chemicals in water. The reference brought us a letter from Messrs. Electric Fires, Ltd., informing us that they were manufacturing appliances of this kind, and would send us some of the first models for our trials. Since then we have had the opportunity of testing two of the three forms in which these electrical heating appliances are made. The first is that shown in Fig. 1, and is a heater for warming considerable bulks of solution, such as those used in the quantity development, etc., of films, or in the development of cinematograph film. The heater consists of a metal tube 45 ins. in length, and shaped like a walking stick. The heater portion consists of a flat blade (enclosing the resistance) forming about 9 ins. of the lower part of the appliance. The heater is simply connected to the lamp-holder of any electric circuit capable of bearing a load of 6 ampères, and is then simply

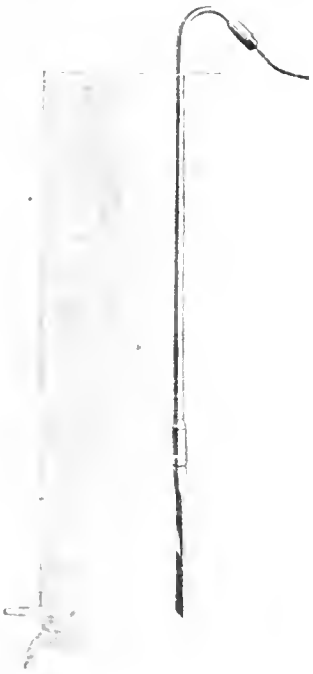

Fig. 1.

Fig. 2.

Fig. 3.

used as a stirrer in the solution which is to be warmed. Using about three-quarters of a gallon of water at an initial temperature of 68 deg. F., we found that approximately the temperature was raised 10 degs. during each 3 minutes' action of the heater, that is to say, in 12 minutes the temperature had been raised from 68 deg. to 108 deg.

Heating at this rate continues approximately uniform until the water is brought to practically boiling heat. It will thus be seen that the heater provides a most convenient and expeditious means of bringing working solutions to a convenient degree of warmth during the cold weather and likewise of providing hot water for dissolving chemicals when making up stock solutions. For this latter purpose the chemicals need simply to be put into the cold water, the heater immersed and the whole stirred occasionally until solution takes place. The convenience of warming water in this way without the necessity of placing the containing vessel on an intense source of heat, such as a gas ring or coal fire, is one which scarcely needs to be recommended to those employing photographic solutions on a considerable scale. The price of this heater, complete with 6 ft. of flexible cord, is £2 10s.

A smaller pattern of tubular heater is made, as illustrated in Figs. 2 and 3. Like the former its consumption is 600 watts or 6-10th of a unit, per hour, but it is of smaller dimensions, namely, 11½ ins., for use in shallower tanks or in large dishes, or, as illustrated in Fig. 2 for dissolving chemicals upon a smaller scale. The price of this heater is £1 19s.

In addition to the above Messrs. Electric Fires, Ltd., have designed an electric hot-plate specially for the use of photographers using either dishes or developing tanks. The plate is 11 x 8 ins. in area and stands 2½ ins. high. Its current consumption is, again, 600 watts. Naturally the heating efficiency of an appliance of this kind is not equal to one in which the heating element is immersed in the liquid, but perhaps for such moderate increments of temperature as are required for photographic solutions, this is an advantage rather than otherwise. Some idea of the rate at which a bulk of solution is warmed by the hot plate will be gathered by saying that three-quarters of a gallon of water contained in a tank of enamelled metal, was raised in temperature from 67 to 120 deg. in half an hour, that is to say approximately at the rate of 2 deg. per minute. A smaller bulk of solution, particularly if contained in a flat dish, presenting a larger area of contact with the hot plate, is raised in temperature at a more rapid rate. The price of the Heatrae hot plate, inclusive of 6 ft. of flexible cord, is £1 2s. 6d.

After having had ample opportunity of noting the use of these

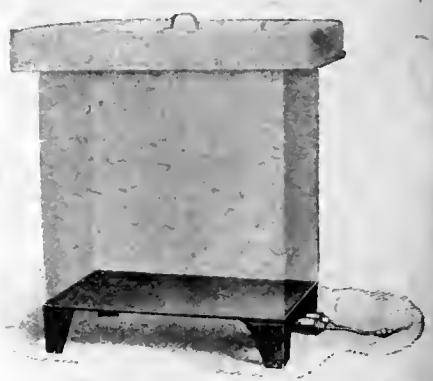

Fig. 4.

appliances, we can thoroughly recommend them. The professional worker will welcome them as still another step towards a ready standardisation of working conditions, whilst amateurs who can use electric current will find them veritable luxuries in the dark-room.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Sunday, June 18.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, June 13, Mr. Dudley Johnston in the chair.

A purely technical evening was spent, under the control of the Pictorial Group.

Mr. F. T. Usher delivered a lecture on the "Matt Surface" plates of Messrs. Elliott and Sons Ltd., of Barnet. These plates, placed upon the market a month or two ago, contain, he explained, a very finely divided substance in the body of the emulsion. Their manufacture had been undertaken as the result of the correspondence on halation in the "British Journal of Photography" last year. Mr. Usher, as a technical photographer of many years' standing, had long taken a special interest in the non-halative properties of dry-plates, and had come to the conclusion that a chief factor in the elimination of halation was the character of the emulsion surface. By way of evidence in support of this view, he showed a number of lantern slides from negatives taken on unbacked plates of subjects which presented every opportunity for the production of halation. The latter, however, was conspicuous by its absence. Some of these negatives had been taken on the Barnet "Studio Ortho" plate. Mr. Usher considered that, in addition to the physical characteristics of the emulsion film, its colour-sensitive properties, and particularly the presence of a screening dye, greatly reduced the tendency to halation. In the "Matt-Surface" plates great scatter of light was produced by the material incorporated with the emulsion. The lecturer showed a large number of slides, from negatives by himself and others, which formed an exceedingly fine testimonial of the plates as regards freedom from halation under the most trying conditions. Some of these were of a high-power half-watt lamp, the lettering on the bulb and the form of the filament being sharply rendered. All were taken without any backing on the plates.

As regards the enlargement of the negative, he pointed out that it was inadvisable to use a condenser lantern with a point source of light, on account of the magnification of the grain of the scattering material, but if a sheet of ground glass was used behind the negative for diffusing light, the enlargements showed no evidence of the particular character of the emulsion film. The matt surface of the negatives allowed of retouching being done with extraordinary ease. The surface received ordinary lead pencil as readily as a sheet of paper.

In the somewhat lengthy discussion which followed, Mr. A. C. Banfield said that he has used a large number of the plates for studio portraiture, and considered them ideal for this work. He found it impossible to get halation on them, even under such critical conditions as the use of a powerful spot-light immediately behind the sitter.

In reply to a question, Mr. Usher said that the plates were made in two speeds, the faster being issued as 550 H. & D. He regularly used amidol without bromide as the developer. Generally, with any plate, it was his custom, if the subject threatened halation, to develop detail first, to remove the plate from the developer at an early stage, and, after fixing, to obtain the required gradation by intensification.

Mr. K. C. D. Hickman then appeared to take advantage of the last evening of the session available for the purpose, to show a most ingenious pneumatic device of his invention, serving for keeping chemicals in constant movement when making up a solution, likewise for keeping prints in movement in the fixing bath, and also for giving a rocking movement to dishes, etc. He had named the appliance an "agitator and solutioner." It consisted of an arrangement of communicating glass tubes and bulbs, which could be fixed anywhere on the workroom wall. When supplied with a moderate continuous stream of water, it caused an intermittent rise and fall of water in an open-ended glass bulb which could be immersed in a bottle or developing dish. The bulb was connected to the apparatus by a length of rubber tube. Mr. Hickman demonstrated the device, and showed the speed with which the necessary quantities of sulphite, carbonate, etc., for a developer stock solution dissolved in cold water by the use of the apparatus without any attention. Moreover, the chemicals were dissolved without agitating the liquid in contact with air. The bulb, in like manner, could be placed in a fixing bath containing prints, and then served to keep the solution in movement.

Votes of thanks to the lecturers brought the proceedings to a close.

CROYDON CAMERA CLUB.

It happened that a little while ago Mr. Handel Lucas gave a lecture on colour. Few know better how to mix and apply pigments to canvas, and few would have had the pluck to advance, as he did, theories hardly in accordance with modern conceptions relating to the science of colour.

Of course, it is no more necessary that a painter should grasp these conceptions than a photographer should know, say, the theory of the objective plane. But an enterprising secretary thought otherwise, and immediately booked three scientific toughs to exterminate the honest opinions of the artist, and incidentally to afford instruction to others on a subject none too easily understood in all its bearings.

The trio were neatly announced on the notice-board by Mr. Sellors as follows:—"The Three (Colour) Blind Mice, Messrs. J. W. Parkis, L. J. Hibbert, and E. G. Budd, will run up the Artist's Clock." Three to one! On the face of it an unfair contest.

On points, it must be admitted, Mr. Lucas was laid out for decent burial time after time, but points and actual fighting are two very different things, and when it came to fighting, never was he seriously shaken. Hard pressed in the "additive" corner, he nimbly dodged to the "subtractive" side, and by the time the bewildered three had followed him there, back once again he was in the original position. Details of the rounds must, perforce, be omitted, but in fairness it should be said that not once had the combatants to be separated for mental contact.

The "elusive Pimpernel" was ably seconded by Mr. Harpur, who jabbed in at intervals, and further distracted the luckless trio. His classification of a yellow shown (formed by overlap of red and green rays) as "tobacco juice suffering from an attack of jaundice," did not meet with the approval of the lecturers.

Apart from their failure to demolish Mr. Lucas, in all other respects they did right well, and with Mr. Hibbert as the main speaker, explained in the most lucid fashion the science of colour as applied to the mixing of coloured light, and pigments, and the cardinal points of difference between the two. Many pretty experiments were included in the intervals between the rounds.

When all parties had retired from the ring (Mr. Lucas as fresh as paint, the others in not quite pristine condition), the former summed up his position. He vastly preferred common sense to science—(cheers)—and pointed out that since teaching had been contaminated with scientific heretical dicta on colour, art had been going down, and down, and down. This drew an energetic protest from Mr. Budd, who thought it hitting below the belt to fasten the freaks of futurists, and others of that ilk, on the unfortunate scientist.

POSTAL EXPEDITION!—We see in the daily Press that the Crown Hotel, Broxbourne, Hertfordshire, received a few days ago a postcard despatched twenty-three years ago by the Hackney Photographic Society, ordering accommodation for a party. The secretary of the Hackney Society is now sending out his correspondence relating to excursions for the year 1945.

News and Notes.

£3,000 Competition.—In addition to Mr. George Robey, Mr. W. L. F. Wastell, and the others mentioned last week, Miss Phyllis Neilson Terry will be one of the judges in this competition for photographs from negatives on plates.

Apem Notes and News for June contains particulars of a new Apem box form roll-film camera, a new Rajar extra-vigorous bromide paper for D. and P. work, and of an inexpensive dry-mounting press of new pattern for the amateur. "Notes and News" is obtainable, free, only by dealers in photographic requisites, on application to A. P. M., Ltd., 3, Soho Square, London, W.1.

Glasgow Housing Exhibition.—In connection with the Housing and Health Exhibition promoted by the Glasgow Corporation, and to be held in September and October next, a photographic competition will again be organised, and will include sections for all classes of workers, pictorial, technical and juvenile. Prizes will be awarded. Particulars and entry forms from Mr. C. P. Hainsworth, Kelvin Hall, Glasgow.

Picture Postcard Enterprise.—Some very artistic photographs of the new L.C.C. Hall at Westminster—the productions of the well-known Dundee firm of Valentine & Sons—were on sale in London within six days of the removal of the scaffolding, certainly a feat considering the long distance of Dundee. The point of view selected—and an unusually good one—includes Westminster Bridge, with the statue of Boadicea in the foreground.

Feet in Photographs of Groups.—A society paragraphist in the "Star" writes that the society bride who intends to have her bridal group in all the illustrated papers really ought to take steps to instruct her attendants in the art of sitting or standing. Nine out of ten bridesmaids endeavour to twist their legs round the legs of the chair they occupy or else cross their legs and show an unnecessarily hoydenish expanse of silk stocking. Even the bride herself is not always guiltless. Operators who are called upon to take such groups may profit by the hint.

Ross Window Bills and Showcards.—Messrs. Ross, Ltd., 3, North Side, Clapham Common, London, S.W.4, send us a large parcel of the many window bills and showcards which they have prepared for the use of dealers. The number and variety of these showcards and their extremely handsome appearance will be sufficient to remove from a dealer's mind any feeling he may have entertained that British lens makers were not doing as much as they could towards promoting demand for their instruments on the part of the public. The showcards consist of actual photographs, ranging in size from 7 x 5 to 12 x 10 inches of attractive subjects, among which are portraits, nature studies, sports, architecture, and the inevitable bathing girls. The prints are most artistically mounted on heavy art boards provided with suitable borders and with hinged struts for convenience in window dressing. There are also one or two showcards consisting of striking artists' drawings in colour of popular sporting events. Among the selection are also some smaller window bills measuring 8 x 6 and 6 x 5 inches, and emphasising the merits of Ross lenses. In addition to this advertising matter, which makes its appeal to the eye, Messrs. Ross supply for distribution to customers over the counter an attractive 24-page booklet, "The Choice of a Lens," containing many reproductions of the work of Ross lenses and instructive letterpress on the selection of an objective for a photographer's special purposes. Dealers throughout the world who are selling the Ross optical manufactures should see that they have a supply of this most effective sales-making literature.

Portraits in Water-colours.—When we chronicled, a month or two ago, the re-arrangement of the former firm of Jeffery and McLeod, we omitted to refer to the fact that the artist partner in this firm, namely, Mr. Angus McLeod, was continuing individually to follow his profession at 3a, Sandringham Parade, Ealing, London, W.5. Mr. McLeod has so long and so deservedly enjoyed a high reputation among the artists contibuting to the success of portrait photographers, that it is due to him to refer to his established status in this capacity, and an opportunity of seeing a collection of examples of his recent work is one which we were very glad to have. Twenty five years' practice in the making of water-colour portraits from photographers' originals have served only to enhance the artistry of Mr. McLeod's work and to emphasise his versatility. An artist whose work supplements that of the studio photographer has necessarily to confine his style, more or less, within limits which are imposed upon him by the nature of the originals with which he is called upon to deal. Nevertheless, the thorough training, such as Mr. McLeod had in the Scottish and English art schools, shows itself in the qualities which an artist such as he can give to enlargements or prints in water-colours and oils. Examples which we examined with a great deal of pleasure included some most attractive styles, among them one, the Leslie, in which an oval portrait in water-colours is presented on a single piece of paper, with plate sunk surround of the oval. In another, the Shannon, an attractive tapestry effect is worked into the background, again of an oval portrait. A peculiarly rich yet delicate style of portrait, recalling the French mezoztints, is the Willis, in which a tint of deepened cream is given to the background, whilst the portrait space is provided with the ruled and toned borders after the admirable manner of the French water colourists. Still another, the Richmond, which well emphasised the variety of technique at the command of Mr. McLeod, was a water-colour portrait having the full saturated richness of an oil painting. But Mr. McLeod's work is not only in water-colour; it includes enlargements in monochrome finish, and also enlarged portraits with the minimum of artist's work upon them. Moreover, a branch of work in which he has long specialised is the reproduction of faded photographs, old engravings, and other originals, fresh and better reproductions of which are often wanted. When we have added miniatures in water-colour on ivory to the list of his various branches of artistic work for portrait photographers, we have, perhaps, said enough by way of emphasis of the work of one whose craftsmanship has earned widespread recognition among leading makers of photographic portraits.

CINEMATOGRAPH PORTRAITURE.

To the Editors.

Gentlemen,—It was very gratifying to us to see your leaderette upon the excellent work done by Miss Olive Edis in connection with the above.

You will recognise that during the course of last year we consistently advertised in your "Journal" and issued other propaganda on the lines of advising professional photographers to adopt this line as an adjunct to their regular professional photographic business.

It has been a matter of disappointment and concern that the response we have had has been so unimportant. The success of Miss Edis, apparently with our apparatus, should be a great incentive to other professionals. When we have discussed this matter from time to time we have always been told that the outlay is prohibitive for such an installation, but as we have so often said, this is a mistaken idea. The outlay to do work such as Miss Edis does is as follows:—

A camera, a spare film box and a tripod, an outlay *under* £40, which is subject to a discount.

There is no necessity for further outlay for developing and printing outfits unless the business grows to considerable dimensions, for there are first-class houses who undertake this work and carry it out well and expeditiously at reasonable prices.

Besides this, there is a further development for sales by the professional: they should have, if possible, in their studios a small home cinematograph for demonstrating the films taken, which can be purchased at a price of about 16 guineas. By demonstrating on this machine it is obvious that it must make sales of such machines for the professional, for the class who will commission the photographer to take film subjects such as Miss Edis takes are the class who will be ready to outlay a further small sum for the purpose of displaying the films themselves in their own homes,

and further than this, those who have machines in their own home constantly want additional subjects, and for general amusement purposes there are available films of general interest for display in the home.—Yours faithfully,

pp. W. Butcher & Sons, Ltd.,
Isidor Joseph,
Director.

Camera House, Farringdon Avenue, London, E.C.
June 12.

DEVELOPMENT OF WARM BLACK BROMIDES.

To the Editors.

Gentlemen,—With reference to your note on p. 334 on warm black bromides, you recommend the use of chromium bleacher, followed by amidol to improve the colour. This works well with most brands of paper on the market, but there are one or two in which this treatment usually gives yellowish-whites, even if all the usual precautions are strictly observed. I have not discovered the reason, but if trouble is experienced in this direction it is recommended that the bleaching bath be made up with potass ammonium chromate or ammonium bichromate in place of potass bichromate, and that the bath once used should be thrown away. Even this procedure is not certain with some grades, semi-matt and glossy particularly, of some brands, and operations conducted by artificial light with a borax M.Q. developer seems to give less tendency to stain. Not being a chemist I have not been able to carry the experiments I have made to a definite conclusion, but if the print with all precautions shows degraded whites, the permanganate, acetic acid, and salt bleacher published by you recently will often clear the print—if it is worth the trouble.—Yours faithfully,

A. H. Hall.

Eliot Vale, Blackheath.
June 10.

DO ACID FIXING BATHS CAUSE BLISTERS?

To the Editors.

Gentlemen,—With reference to the above inquiry, made by a correspondent in your issue of 2nd inst., I, too, am a constant user of the alum-acetic fixing and hardening bath, recipe for which is given on p. 454 of the current "Almanac," but only for certain plates and those it is specially recommended for—the "Barnet," for example.

Used in a normal condition—as advised in the "Almanac"—the bath will suit any make of plate, but any increase of the hardening part, and more particularly the acetic acid, means blistering with some makes of plates, especially some of the ultra-rapid ones.

The rather primitive experiments I made some time ago led me to come to the conclusion that the acetic acid in the fixing and hardening bath had a solvent action, not only on the gelatine film, but upon the substratum, an action the hardening effect of the alum was not sufficient to counteract.

The obvious remedy is to follow the instructions given in the "Almanac" and by makers, however hot the weather may be, and not to imagine that you can improve upon the methods introduced and advocated by experts, and who arrive at conclusions only after much experimenting in a really scientific manner.—Yours truly,

C. H. O.

ENLARGING WITHOUT CONDENSERS.

To the Editors.

Gentlemen,—Your article in current issue of the "Journal" on enlarging without condensers is very misleading and incorrect. You state in paragraph 2, "Arc lamps are too clumsy and troublesome to be used in an average dark-room."

Having over twenty-five years' experience of enlarging by every known method, I beg to state most emphatically that the best, most perfect, and up-to-date enlarging apparatus manufactured to-day is Boardman's automatic condenserless enlarger fitted with four arc lamps, which are of very light construction, powerful, fool-proof, safe and efficient. The carbons are renewed in half a minute, burn steadily and continuously for hours without attention, noise, or flicker. The light is perfectly diffused without any additional ground glasses or other auxiliary nuisances, and, unlike mercury-vapour or condenser types, it is very comfortable to work with, never reproduces hand work from the negatives, and does not crack or blister negatives when left in the lantern for a considerable time. It is a great time-saver, the light is fixed and constant, and does not require centering as in a condenser type; also there are no condensers to steam off in cold weather. The current consumption is less than 10 amps; average exposure six seconds. An efficient and economical enlarger has yet to be devised to equal it.

I hold no brief for the makers, Marion and Co., but can recommend a piece of apparatus when I use it daily and find it indispensable and far away the best.—Yours truly,

George Turner.

13, Eccleston Street, London, S.W.1,
June 13.

[We agree with our correspondent that it was an oversight on our part not to have excepted the Boardman condenserless arc enlarger from the remark made in the passage which he quotes. Employed as a battery of four, the arc lamp is admirable as the light-source for illumination by reflection. We should have been more explicit in confining our reference to the older patterns of arc, occupying much more space and requiring more frequent adjustment.—Eds., "B.J."]

BLUE SCREENS IN COPYING STAINED PRINTS.

To the Editors.

Gentlemen,—As a tone and colour process operator who is frequently handling prints of the character described by your correspondent, Mr. C. Venning, in the "B.J.," of June 2, may I be permitted to express considerable doubt as to the results obtained with blue filters.

The first instance is not at all surprising as regards the ink stain (presumably bluish), which would naturally be suppressed. It is the "somewhat expected result," which is surprising, inasmuch as it is contrary to both theory and practice.

That a filter transmitting, say, roughly, only wave lengths between, λ 4,000 and λ 5,200 should improve the reproduction of a yellowed print will need a big stretch of imagination on the part of most practical operators before acceptance.

If Mr. Venning's second instance is correct, our present colour processes are inside out. I pity the fine etcher who has to etch a blue plate with the yellows, etc., "eliminated by a blue filter," or the retoucher sitting down to the negative of a yellow freckled client taken under similar conditions.

However, it was some years ago, and Mr. Venning was only in the experimental stage, so that he may have confused the entries in his record. It is also possible in the first instance, that the conditions of exposure and development were so altered as to produce a much more contrasty negative, thus neutralising the effect of the filter, which ordinarily would darken the yellowish high-lights.—Yours faithfully,

J. F. Milner.

364, Humberstone Road, Leicester.
June 8

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—The controversy raised by Mr. Bierman in your columns, regarding half tone operating, is a timely reminder of the fact that present-day half-tone practice is losing touch with the demonstrated principles upon which it is based. The confusion of thought created by opponents and exponents alike is, in fact, so extensive that it is difficult to employ even such familiar terms as "pinhole," "diffraction," or "normal distance," without raising a whole crop of misunderstandings.

Mr. Bierman will pardon me for suggesting that he appears to have completely misread the article in the "Process Year Book," 1898, by my father, the late Mr. U. Ray, and consequently misunderstood its teachings, and conclusions to a very material extent. I may point out that the diagram on page 37 of the "Year Book," which he describes as showing "that the enlargement of a stop would actually decrease the nucleus of the dot," refers only to distances below the "normal," and that it definitely excludes, as a footnote is careful to explain, all cases "where diffraction is a prominent factor." Mr. Bierman finds himself unable to reconcile the "pinhole theory," with the practice of employing two or more different stops in making a single exposure. This is due to a very common miscalculation which overlooks the fact that sectional diagrams of the nucleated pinhole image do not fully represent the actual conditions obtainable in half-tone practice, except in the solitary case of the square stop placed, diamond fashion, with its sides parallel to the screen lines. With the usual round or square stops, the position

for perfect gradation is diffused within fairly wide limits. This is fully explained on page 36 of the article in question. The lower of these limits, I may add, is that much maligned entity known as the normal distance.

While fully recognising the influence of diffraction as an important factor, I am afraid that I am unable to follow Mr. Bierman when he speaks of measuring the amount of diffraction, or of diffraction being in proportion to this or that optical factor. But if, as I presume, he has measured the growth of the half-tone dot under various definite conditions, the information ought to be of great service to process workers. After all, what we really require for systematic practice is some quantitative study of the phenomenon, as a whole, which should give us definite data regarding the effect of varying conditions of stop and screen distance on the rendering of gradations by the half-tone screen.

In Mr. Bierman's experience, the equation, on which Messrs. Smith and Turner's system is based, does not hold good for the wide range of screen rulings from 50 to 200. That may be so, but it only proves that some correction is necessary, and by all means let us welcome that correction formula when it is forthcoming. So long as the necessity for such correction is definitely established, it is immaterial whether we ascribe it to diffraction or irradiation, or some ocult influence. But, in any case, the equation itself, or some similar expression in terms of screen ruling, camera extension, diaphragm aperture and screen distance, must of necessity continue to be the basis, not only of this, but of any other system that may be desired.

In this connection, Mr. Bierman raises a very pertinent question when he speaks of obtaining "identical negatives," or "a similar effect," with widely different screen rulings. Considering that the range of contrasts in a half-tone reproduction is demonstrably different with different screen rulings, is it really necessary that 50-line and 200-line negatives should have "the same gradation"? If not, what is the criterion or basis of comparison, that would enable us to say definitely what corrections, if any, are necessary for different screen rulings? The question is evidently one of much greater complexity than appears on the surface.

The one thing lacking in all process "systems" that I have come across is some simple method of measuring the total range of gradations in the original; for it is this factor which determines the degree of departure from "normal" conditions that may be necessary for the proper reproduction of a particular copy.—Yours faithfully,

SUKUMAR RAY.

100, Gurpar Rd., Calcutta.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S. B.—We have now looked up the references to production of positives direct by means of thiocarbamide. These are:—"B.J.," October 11, 1912, p. 788 (a brief *résumé* of work by Frary, Mitchell, Baker, Perley and Leighton). "B.J.," November 1, 1912, pp. 840-842 (by Frary, Mitchell and Baker). "B.J.," November 8, 1912, pp. 860-864 (by Perley and Leighton). "B.J.," March 12, 1915, p. 167 (a practical note by F. B. Guilbert). So far as we remember there has not been anything published on the subject since the last paper.

H. H.—For such small negatives it is a comparatively simple matter to arrange a light-box to work either entirely by reflected light or by a mixture of diffused direct light and reflected light. In the former case you arrange the lamps, either inverted mantles or electric, on each side of the negative, the whitened back of the light-box being, say, 5 or 6 ins. from the negative. For incandescent gas the second system is best used with a vertical pattern of camera, the light from one or several mantles being contained in a whitened box and also diffused by a sheet of ground glass placed about an inch above the negative. Although these systems require rather longer exposure than when a condenser is used the results, particularly with retouched negatives, are much better.

J. H.—The formula for the ferro-gallic process given in the "Almanac" works quite satisfactorily, at any rate so long as the paper is used within a fairly short time of being coated. If the whites are degraded to more than a faint bluish tint, the fault is evidently insufficient exposure under the tracing. You will understand that in this process it is necessary to act fully upon all the iron salt which occurs in the ground of the copy when the original is a tracing in opaque lines on tracing cloth or similar material. The bluish-black lines in the copy are formed by the iron salt which is left undecomposed. Therefore, exposure must be continued until the yellow tint of the paper has entirely disappeared from the parts which are to be white in the copy. The process is not suitable for printing from negatives but only from line tracings.

C. E. GREEN.—As an illuminant we do not think anything is better than half-watt lamps. For your studio you would require at least six 1,000 c.p. lamps, or if you want to give very short exposures 1,500 c.p. lamps. These should be arranged in an L shape, four lights in front and two at the side. To get even lighting with a large group, it would be desirable to make the front lamps run on a stout iron rod across the studio so that they could be spread out when necessary. They should also be made to raise and lower, the greatest height to the filaments being 8 ft., and the lowest about 5 ft. 6in. This will allow you to get short exposures with children and sitting figures. The front lamps should be about 8 ft. from the background, and for ordinary single figures or groups of two, the first lamp should be nearly opposite the centre of the background. You can get all particulars from the General Electric Co., Kingsway, W.C. Mention when writing that the lamps are required for photographic work.

K. B.—(1) We do not know a formula without ammonia, but the following is an excellent one for simultaneous development and fixing of ferrotype plates:—

Water, to make	40 ozs. fluid.
Hydroquinone	½ oz.
Soda sulphite	4 ozs.
Soda carbonate	4 ozs.
Hypo	8 ozs.
Liq. ammonia .880	2 fl. ozs.

Addition of more ammonia to the developer gives more vigour. The plates develop (and partly fix) in two or three minutes. They can then be examined in daylight and fixed in plain hypo.

(2) Several chemicals, or mixtures of chemicals, will dissolve the silver image without affecting the undeveloped silver bromide. Potassium or ammonium persulphate is one of these, but the solution most commonly used is a mixture of potassium permanganate and sulphuric acid, or potassium bichromate and sulphuric acid. A formula for the permanganate mixture is that recommended for the "reversal" of Autochrome plates.

Contents.

SUMMARY.

The last meeting of the Committee appointed under the Safeguarding of Industries Act to inquire into the importation of German optical goods was held on Monday last, when further evidence was given by witnesses for the complainants, and by those for the opponents of the complaint. Mr. A. J. Dennis, of the Houghton-Butcher Manufacturing Co., appeared again to contest previous evidence given by agents for German goods. The Committee's decision will be made known in due course. (P. 371.)

In a leading article we have some hints to give on the arrangement of large groups, and particularly on taking the all-too few opportunities for departing from the customary series of rows. (P. 366.)

We recently received an example of the indifferent psychological insight exhibited by a firm which offers its portraiture free to the public. It is just as well to clothe an obviously invented statement in some pretence of reality. (P. 366.)

Mr. J. C. Elvy, in a letter to the editors, further criticises the recent judgment in the High Court in reference to the supply of electric current at "power" rate for use in photographic studios. (P. 377.)

In the concluding part of his review of recent progress in photographic manufacture and research, Mr. F. F. Renwick deals particularly with theoretical and experimental papers on the latent image and development. (P. 368.)

A contributor, Mr. C. R. Denton, emphasises the revival of view postcards which may be expected to follow the recent reduction of the postal rate to a halfpenny, and adds some hints on the making of view cards for local sale. (P. 367.)

A German experimenter, Dr. Strauss, has suggested a variation of the Ferguson copper-toning solution. He uses oxalate instead of citrate, and adds a small proportion of chromic acid. It is claimed that the mixed bath keeps well. (P. 365.)

The usefulness of the water-bath method of development for subjects having a great range of tones is the subject of a paragraph on page 365. Development is started in the usual way, and the plate transferred to a dish of plain water as soon as the image appears. Excessive density in the high-lights is thus avoided.

A certain reduction in lens speed is produced by the operation of a diffusion adjustment or the use of a separate diffusion attachment. Although almost negligible in practice, it is as well that the tendency of the alteration should be borne in mind. (P. 366.)

A contributor to "American Photography" describes how to fit a single uncorrected spectacle lens for use in making soft-focus effects at an aperture of about *f*/5. (P. 372.)

Plant for the continuous development, etc., of cinematograph film is described in a recent patent specification. (P. 372.)

EX CATHEDRA.

Copper Toning. It might have been thought that every conceivable variation of toning development prints with mineral salts had been tried. Dr. Sellneczek some years ago did a good deal towards exhausting the possibilities, but in the current issue of "Photographische Rundschau" a Dr. Strauss ventures still another variation of the Ferguson copper toning process. He uses oxalate instead of citrate for keeping the copper ferricyanide in solution, and adds a little chromic acid. His formula is: 10 per cent. copper sulphate solution, 5½ drams; 4 per cent. ammonium oxalate solution, 7 ozs.; 20 per cent. potass ferricyanide solution, 5½ drams; 5 per cent. chromic acid solution, 2½ drams; water, 10 ozs. The chromic acid is used as an aid to keeping the whites clean, and the process is said to reduce the contrast of the black print. Considering the presence in the solution of the oxidisable oxalate and an oxidising substance, such as chromic acid, it is rather strange that emphasis should be laid on the keeping qualities of the solution.

* * *

Water Baths for Strong High-Lights At this time of the year it is often found difficult to get good printing negatives of subjects containing very strong high-lights. We refer principally to portraits of persons dressed in white. The negatives obtained are usually hard, and require a large amount of rubbing down, or local reduction, to get printing detail in the strong portions. This can be avoided by care in development, and the easiest method we know is to use the "water bath." The developing solution need not be altered in any way, and one's own pet formula may be used. When commencing to develop a batch of exposures of the subjects mentioned a large dish should be provided, capable of holding say, four or six plates of the size used. This dish should be filled, to a depth of about one inch, with water, and thus constitutes the water bath or "control dish," as it is sometimes called. Let development be started in the usual way and the plate carefully watched for the first sign of darkening action. When this occurs (it is, of course, the highest light, in this case the white frock) the plate is removed to the dish containing water. A slight rock both ways should be given, to remove the surface developer. If this is not done, mottled markings often make their appearance. The dish should now be covered with a piece of card and the next plate put in the developer. When darkening has commenced, this also should be transferred to the water bath, and so on, until the dish is full. The first plate will now be found to be full of detail, and often sufficiently developed to allow of immediate fixation. If, however, the density is not sufficient, the plate is placed back in the developer and development continued until the density is of the required depth. The theory of the process is simple. Developing solution is soaked up by

the dry gelatine, and, when the plate is put into water, continues its action until it is used up. Consequently, in the high-lights it is used up quickly and development stops, while that in the shadows continues active, and has a better chance, than it would have, in a strong solution. Excellent printing negatives can be made in this way, giving full detail in the high-lights, while the shadows are not too thin.

* * *

Diffusion. Neglecting the old mechanical methods, which gave erratic and unsatisfactory results, the portrait photographer has two methods of securing diffusion. One is by altering the lens in some way so as to introduce aberration, the other is by placing diffusion discs in front of the lens; it is worth while considering the drawbacks of each. If the separation of the components of the lens is altered, then will also the focal length be altered, and the more the diffusion, the greater will be the alteration of the focus. Furthermore, the alteration in focal length will produce a corresponding change in the effective aperture, and therefore in the speed, of the lens, since the diameter remains unaltered. In every lens but one on the market the focal length is increased when the lens is set for diffusion, and the speed correspondingly diminished. The alteration in focus may amount to as much as 10 per cent., and in speed, therefore, to 20 per cent., not an alarming amount, but one which is worth considering. The second method, by the use of diffusion discs, does not alter the focal length in any way, and is to that extent preferable, but owing to the introduction of two glass-air surfaces the diminution in rapidity is about 10 per cent., as about 5 per cent. of the light is lost by reflection at a glass-air surface. Moreover, in any diffusion method, since the light, which would normally go to the focus, is deviated, there must be a further diminution in rapidity.

* * *

The Free-Sitting Game. Some portrait photographers, who adopt the practice of offering their work for nothing, must have a very low opinion of the intelligence of the public, or, alternatively, must be singularly lacking in penetration. We had an instance of this a few days ago in the shape of the offer of a free portrait addressed personally to the editor of the "B.J." by an eminent firm in the west end of London. The circular letter starts off by saying that the press department of the studio is frequently being asked for a portrait of ourselves by the editors of the illustrated newspapers. We wonder if the photographers really expect that statement to be believed by us, or by the other members of a certain society, from the membership list of which, as we are able to identify, the address list of their circular letter has been compiled. The people to whom they are writing are by no means in the public eye, and most of them will scarcely relish the doubtful compliment implied by the intimation that their portraits are required for admixture with those of co-respondents, murderers, and shady financiers in the pages of the illustrated Press. But passing from this example of an obvious misjudgment of human nature, we come upon another. If the recipient of the letter happens to be vain enough, or gullible enough, to swallow the bait, he sends a card (provided for the purpose) to make an appointment. We should have thought that it was worth while to acknowledge the alleged favour, which is thus being done by complying with the photographer's request. But not at all. There is the curt intimation that if no acknowledgment is made, the prospective sitter is asked to assume that the appointment has been made as requested. Naturally, like all other literature, touting for free sittings, which we have seen, this circular letter is careful to avoid saying that the photographer acquires the copyright in the portraits and is thereby entitled to use them for any purposes that he chooses.

LARGE GROUPS.

The arrangement of a group containing over a dozen figures does not allow much scope for artistic arrangement, unless the setting is particularly favourable, such as was the case of a Photographic Convention group taken some years ago in Jesmond Dene. This was arranged upon a hill side, the members being more or less scattered among rocks and foliage. Such surroundings are, however, seldom met with, and the most that usually can be done is to make a well-balanced, well-lighted picture of a rather formal arrangement, the nature of which must depend upon the facilities to hand and the number of people to be included.

The photographer must be quick to note any natural advantages of the place and utilise them accordingly. If the background is formed by a building with wide steps ascending to the entrance, the task is a comparatively easy one; successive rows can be arranged one above the other, with the front row seated upon chairs or forms. But there are many cases in which less promising material has to be utilised. As an example of what may be done, the following was the plan adopted in making a series of groups, each containing about forty persons, who were visiting an important building operation. A position was taken up opposite a bank of earth which had been excavated from a part of the works. In front of this, boards were laid upon empty boxes, sacks of cement and any other handy supports, and the front row seated closely so as to hide the contrivance. Behind were two rows, one standing upon the level and the other upon the bank. If the ground had been covered with turf, or mats available, another row could have been seated upon the ground, but wet clay and cinders prevented this being done. Another very large group was managed by borrowing several loads of 3 x 9 deals from a near-by timber yard and piling these so as to form steps. The deals were not cut or nailed, so that they were not spoiled for sale, and the greatest expense was for labour in moving them.

For a group of 30 to 40 members the usual plan is to arrange for four rows, the back one standing upon chairs, forms, boxes or any convenient substitute, the second row standing upon the ground, the third row sitting upon chairs or forms, and the front row sitting as gracefully as possible upon the ground or upon boards supported at a height of about six inches.

In placing the sitters the photographer should always seek the aid of the secretary or other official in charge of the affair, so that the most important personages can be placed in the position of honour; that is to say, the centre of the row sitting at the ordinary height. If it can be avoided, the heads of the back row should not be silhouetted against the sky. But it is not always possible to do this, and therefore it is very desirable that backed plates be used so that the risk of halation is minimised. An efficient shade for the lens should be provided; then, if it is necessary to work facing the sun, all unwanted light can be screened off.

Coming to groups in the studio, the schemes of arrangement will be practically the same; the greatest difficulties which are likely to present themselves are insufficient width and unequal lighting. The former can, to a certain extent, be overcome by arranging for an extra row, or,

as had to be done recently, by taking the group in three sections, joining them to form a panorama, and copying. In this way a party of 120 was photographed in a studio less than 18 feet wide. A convenient way of equalising the lighting is to close the white blinds or curtains of the end nearest the group, so that the light is softened for those nearest the glass. The top and side lights are fully opened at the camera end, and a white background or large reflector placed on the shadow side out of the field of the lens. With this system the lighting will be practically even, right across the plate.

It is very desirable to use a lens having as great a focal length as the space available will allow; nothing is more objectionable than to see the faces of the front row of sitters on a noticeably larger scale than those at the back. Very rapid and consequently expensive lenses are not necessary, since the aperture must be reduced to something between *f*/11 and *f*/22 to obtain the necessary depth, even when the swing-back has been utilised. Hence a lens with a maximum intensity of *f*/8 will do all that is needed. An anastigmat is, of course, to be preferred, but a good rectilinear, if of sufficiently long focus, will cover its normal plate perfectly at *f*/16. If a lens, having a focal length less than the diagonal of the plate, has to be employed, it must be an anastigmat.

The method of identifying the sitters in a large group which is usually practised, is to provide cards, say six inches square, which have large figures from 1 up to the total number of sitters printed or stencilled upon them. After making the exposure, these are handed round, and each member asked to write his name and address upon the back. A second exposure is then made, each person holding the card nearly covering his face. If an order form is attached to the back of the card, this can be filled in, and the cash collected by an assistant.

Lately, panoramic cameras which will embrace a very wide angle have been largely used for this class of work, but a word of caution is necessary as to the choice of a background. If this be foliage, the effect will be good, but the rendering of a building is sometimes very unpleasant; there is the tendency for a perfectly flat facade to look as if it were strongly convex towards the sitter.

PROFITABLE POSTCARD PHOTOGRAPHY.

The reduction of the postal rates is likely to have the effect of increasing the public demand for view postcards, and several manufacturers of these are anticipating this demand during the coming holiday season. The popular holiday resorts and the large towns are well covered by these firms, who have their special photographers, sent to deal with likely subjects, and the local professional or the advanced amateur who contemplates this work as a side-line will not have much chance in competing with these firms unless he can produce cards which are really novel and original.

Apart from the popular resorts and beauty spots, there are many small towns and villages in Great Britain which are more or less neglected by the postcard firms, and these offer a good chance for the enterprising individual. Apropos of this, the writer one day was talking to a newsagent in a small town which was not a holiday resort, but merely a commonplace industrial area. The man said:

"I find it rather difficult to get really good photographic postcards of local views."

"Why is that?" he was asked.

"Most of these were supplied by German firms before the war; and since then no one seems to have done anything in the matter. The demand is there right enough, because many people ask me for them."

It is quite likely that the enterprise of Germany will again extend itself into this phase of British industry as soon as conditions are favourable, and it is up to the British photographer to see that a possible field of profit is not taken away from him. Most of us remember these German "pictorial" products; even the most inartistic photographer amongst us could produce something better than them. And I venture to think that the general public taste is improving, and that there is a growing demand for more tasteful articles, and amongst them more tasteful photographic postcards.

The market problem is the first thing to consider, however, because it is not much good supplying goods which are not wanted. The photographer should have a talk with his local stationer or newsagent on the subject. The latter may already have a supply of view cards, but if the photographer can offer, or, better still, show, him something better he is likely to get future orders.

The photographer who lives in the district has a distinct advantage over those publishing firms who send their own photographers out on tour to obtain negatives. He knows the country-side better, and the most interesting spots will be so familiar to him that he can select the best view-points and the best lighting before he makes his exposures. Most touring photographers have time only for a hasty selection before they pass on to the next district.

This point was brought home to me rather forcibly by a collection of some thirty or forty postcards of a beautiful district. The photographer had motored over about twenty miles, and had taken all his negatives on the one day without any previous selection. About five of the pictures were really good enough to make attractive and saleable postcards, and the rest were failures chiefly because a bad or indifferent view-point had been selected.

If the photographer has not done much landscape or artistic work of an outdoor nature he should take some pains to study the principles of composition before he begins. If he studies some of the excellent etchings of towns and of landscapes which are now so popular, and compares these with the commonplace view-cards more often turned out, he will soon be convinced that a little artistic discrimination makes a huge difference. In passing, it may not be out of place to comment and hold up as example to be studied the really beautiful landscape cards and souvenirs of the Lake district by Mr. Abraham, of Keswick. Some of these are worth getting as examples to study. True, he has beautiful landscapes to photograph, but much of this effectiveness depends upon the view-point and the lighting.

Except when the subject is of unusual interest, view negatives without human figures should be avoided. Figures give a touch of life to a scene. They must be very carefully included when the exposure is made so that they fit in with the composition, and harmonise with the subject. In street scenes especially, they should not be photographed when too near the camera unless they are posed for that purpose; and care is necessary to avoid including the eternal man who will stride right across the foreground and be photographed in that ugly attitude with his legs wide apart.

The technique of exposure and development, of course,

should be beyond reproach both for the sake of the photographer's reputation and his final profit.

A good modern half-plate camera fitted with an anastigmat lens and roller-blind shutter is a very suitable type to use. The picture postcard above all is purely a typographical record of a particular part of a town or district, and it should be as clear, sharp, and bright as it can be made It is not advisable, however, to step down to *f*/64, as the old-time landscape photographer used to do, for there is plenty of opportunity to sell a higher standard postcard which is both artistic and yet possess good delineation.

Unless the photographer is very well equipped for the purpose it is not wise to print the actual cards himself. The best way is to obtain the negative and send this to one of the trade houses who specialise in postcard printing, and who will print any quantity of calotype postcards of each subject which can be done in various tones and styles according to the taste of the producer.

In this article the writer has attempted to point out the opportunities of this class of work to the small professional. Those who think it worth while can study the question of supplies and profit according to local conditions. It is a good plan, however, to work for a large sale with smaller profits rather than a big profit on each and a limited sale. This enables the photographer to produce new negatives more quickly and gives him the chance of introducing new features before the others have time to get old and worn. There is nothing like freshness and novelty even in postcard production; people soon get sick of seeing the same thing too often.

CHARLES R. DENTON.

PHOTOGRAPHIC MATERIALS AND PROCESSES.

[REGULARLY each year the Society of Chemical Industry renders a valuable service to those connected with the manufacturing and scientific sides of photography by including in its "Annual Reports" one on photographic materials and processes. The report for the year 1921 is written by Mr. F. F. Renwick, F.I.C., whose large share in photographic research qualifies him exceptionally as a recorder of recent investigations in the technical improvement of processes of making negatives and positive prints, orthochromatics and colour photography, cinematography, and photo-mechanical processes. The report exhibits the work which obtained publication last year in its relation to previous knowledge better than any other communication which comes before the photographic industry, for which reason we endeavour to find a place for it in our pages. As regards the references to original sources of publication, it should be explained that the contraction "J" denotes the fortnightly "Journal" of the Society of Chemical Industry, in which are published abstracts of the chief papers dealing with the chemical side of practical, scientific, or industrial photography.]

(*Continued from page* 357.)

Reactions of Photographic Images.

A. Steigmann[64] during the past two years has investigated the applicability of the hydrosulphites to various photographic purposes (developing, silver recovery, etc.) but finds them of no great value in most cases, though convenient for recovering the silver from old fixing baths and incidentally regenerating them.

The process of photographic reduction by means of persulphates has received a large amount of attention. Lumière and Seyewetz[65] reaffirm their view that the selective action of these reagents on the denser parts of the developed image is due to the tendency to reversal of the initial solvent action when the silver sulphate first formed is in presence of excess of persulphate, photographic reduction (silver removal) being thereby confined to the deeper layers of the film. They do not accept Sheppard's view that the irregularities met with are attributable to variations in iron content and state that for regular action a definite free acid content of $\frac{1}{4}$—$\frac{1}{2}$ per cent. is alone necessary unless chlorides, which are particularly potent in modifying the action, are present. A valuable historical summary of previous work on persulphate reduction has been published by G. I. Higson, with a very full bibliography.[66] Lastly, a valuable series of new experiments on the subject and a detailed discussion of their probable explanation which has just appeared in a paper by S. E. Sheppard,[67] confirms Lumière and Seyewetz' observations on the importance of the acidity of the solution, and sets the whole matter in a somewhat clearer light.

A useful paper by L. A. Jones and C. E. Fawkes[68] deals quantitatively with the effects of ten different photographic reducing agents upon developed images on paper.

The high degree of permanence attaching to sulphide-toned silver images and the beauty of some of the brown tones so obtained has attracted several workers to the study of sulphide toning processes and, as a natural extension, to the working out of methods of toning with selenium and tellurium.

Lumière[69] claims the use of thiophosphates as sulphiding agents, having the merit of being odourless. The theory of sulphide toning in the hypo-alum bath is partly elucidated in a paper by H. Freundlich and A. Nathansohn,[70] and in a recent paper before the Royal Photographic Society, by S. O. Rawling,[71] the former showing that colloidal sulphur is able to combine directly with colloidal silver, and the latter that at a moderately elevated temperature the same reaction can take place with the silver of a developed print.

A detailed study of the effects of varying the compositions of the bleaching and sulphiding baths and other details of manipulation has been published by E. R. Bullock.[72]

Namias[73] has published several new formulæ for toning with selenium, and a number of patents for selenium and tellurium toning baths have been taken out by German firms.[74] H. Franke[75] has patented a process of intensification by means of selenium.

A new printing process has been patented by the Badische Anilin u. Soda Fabrik.[76] When benzidine or other diamine compound is precipitated with an acid dye (*e.g.*, Eosin, Cyananthrol, Neptune Green, or Quinoline Yellow S) an insoluble compound is formed which in the presence of manganese nitrate or other suitable oxidising agent bleaches in the light. According to the base and the acid dye selected, prints of a large variety of colours are obtainable having good gradation and vigour. Fixing is done in borax or sodium phosphate. Pure whites have not yet been obtained and printing is very slow, but the process appears to be worth further study.

Miscellaneous.

An interesting paper by J. Rheinberg[77] draws attention to the change in permeability to alcohol of certain colloid films containing ferric ammonium citrate after this salt has been reduced by

exposure to light. This phenomenon is the basis of his patents relating to a multicolour screen suitable for colour photography (*vide* J., 1913, 1116; 1914, 513, 637). It is to be expected that a variety of useful applications could be found for this remarkable property of such exposed films.

A new type of electric lamp, "Osglim," is being put on the market by the General Electric Co., having interesting possibilities for dark-room illumination. The light emitted arises from an electric discharge between electrodes in a bulb filled with neon, or neon and mercury vapour. Although the candle-power per watt is very low, recent experiments in the laboratories of Ilford, Ltd., have shown that with suitable safelight screens they are more efficient for dark-room illumination than ordinary metal filament lamps, besides having a long life and generating very little heat, the consumption being only 5 watts per lamp. [Further experiments by B. V. Storr mentioned in a paper before the Royal Photographic Society ("Phot. Journ.," June, 1922, p. 271) have confirmed this statement only for those cases where the illumination must be very weak. For ordinary dark-rooms, for development and such like purposes where comparatively bright light is permissible, the total light obtainable from an Osglim lamp is too small.—EDS., "B.J."]

Theory.

A number of papers of a mathematical nature dealing with the various characteristics of silver bromide emulsions has appeared. In view of the number and complexity of the factors involved, it is unlikely that a mathematical solution embracing all such emulsions will prove possible, so that while a thorough study of all these factors and their inter-relations is highly desirable and is indirectly valuable both to the manufacturer and to those who use dry plates for quantitative work, it would not repay users to determine the "constants" in the very complex equations suggested for the characteristic curve by Ross, Helmick, or Slade and Higson.[78]

The Hurter and Driffield method of determining the "inertia" of a plate is well known to give results of an unreliable character if used alone as a criterion of sensitiveness, because of the considerable variations among commercial plates in the relative lengths of the lower and the middle, approximately straight, parts of the characteristic curve and the uncertainties arising from variations in the amount of chemical fog in different plates and for different times of development. Moreover, in all photometric work in which light-intensities are to be deducted from their effects on photographic emulsions, the greatest care has to be exercised to avoid numerous possible sources of error even when adopting the apparently simple method of comparing the unknown with a series of known values recorded on the same plate or film, so that to rely on values deduced from a formula would be practically useless.

In two important papers G. I. Higson[79] makes an ambitious attempt to reconstruct the Hurter and Driffield characteristic curve by reasoning based on Slade and Higson's paper on the photochemical law of the silver halide grain published last year. While the mathematical reasoning in these papers has met with severe criticism[80] and is based on assumptions difficult in some cases to justify, it is important to note that Slade and Higson's experimental work, showing that "under ordinary conditions of exposure (for times over about $\frac{1}{100}$-sec. and with white light) and with most plates on the market, the density is proportional to the square of the exposure in the under-exposure region" has been confirmed by F. C. Toy.[81]

The experimental section of Higson's second paper merits careful attention from all workers in sensitometry, and lends considerable support to the mathematical introduction.

Methods of sensitometry, based on the properties of neutral optical wedges, are rapidly coming into general use, both in this country and on the Continent. In connection with them a paper by G. I. Higson is a useful addition to the literature of the subject.[81]

A new and rapid method of determining absolute reflection coefficients as the result of two observations only has been worked out by A. H. Taylor[82] and independently by C. H. Sharp and W. F. Little,[83] while the former has devised for the purpose a very ingenious portable instrument which should prove a valuable addition to the equipment of any laboratory concerned with the photometry of paper or other reflecting surfaces, prints, etc.

Several suggestions to employ self-luminous mixtures of radioactive and fluorescent substances as a rough standard of light have been made: (*a*) for the preparation of sensitometric tablets,[84] (*b*) as the comparison source in an actinometer.[85]

Photochemistry of Silver Salts.

Two papers have appeared dealing quantitatively with the photochemical decomposition of silver bromide in strong illumination. In the first, by W. Ehlers and P. P. Koch,[86] finely-divided dry silver bromide particles were "weighed" in an Ehrenhaft-Millikan condenser and found to show a slight gain in an oxygen-containing atmosphere and a loss (reaching 10 per cent. for the smallest particles) in an atmosphere of nitrogen when exposed to a strong light. It is deduced from calculations based on these results, *obtained under very different conditions*, that in the photochemical decomposition of highly sensitive silver bromide by weak light a loss of weight occurs corresponding to approximately 1 Br atom per particle of AgBr. The second paper, by R. Schwarz and H. Stock,[87] deals with the rate of elimination of bromine from wet precipitated silver bromide when exposed to daylight in three different states of aggregation, obtained by adding excess of a potass. bromide solution to an acid silver nitrate solution, and from a fourth variety obtained when excess of silver nitrate was employed. Considerable variations in sensitiveness were observed between the different specimens. The curves connecting the average rates of loss of bromine per hour with the logarithms of the average light-intensities during exposure are said to be similar in type to the characteristic curves of photographic emulsions. Beyond a certain average intensity of illumination a sharp fall in the average rate of loss of bromine was observed, and consequently it is asserted that solarisation is accompanied by a diminution in the rate of its elimination. In view, however, of the difficulties invariably found in making a number of separate preparations of similar sensitiveness on a small scale, the results are of doubtful trustworthiness while, in any case, the above curves do not show the course of the reaction during its progress for any given preparation and for a given light intensity as does the characteristic curve of a plate.

Further studies of the effects of coloured lights on the photochlorides of silver by F. Weigert[88] emphasise once again the marshalling action or regimentation which light waves exert on ultramicroscopic particles, while a new method of preparing silver sols having particles of known dimensions which has been worked out by K. Schaum and H. Lang[89] is a valuable contribution to the question of the relations between colour and size of particle in such complexes, a subject which is discussed by F. Formstecher[90] in its bearings on chlor-citrate print-out processes.

It is being urged by some prominent scientific workers that all chemical reactions and changes of state are initiated by radiation.[91] Confining ourselves to generally acknowledged photochemical changes, however, it certainly seems necessary in all cases to assume that the absorption of light energy leads to a liberation of latent valencies (electrons), or some activation of the molecule, as the initial step in the process, the succeeding stages depending chiefly on the nature of the neighbouring molecules.[92]

The writer's suggested modification of the silver germ theory of the latent photographic image has been criticised by Lüppo-Cramer[93] and S. E. Sheppard,[94] who are both of the opinion that the suggested photoelectric discharge of negative electrons from colloidal

silver held in solid solution in silver bromide (resulting in electrically neutral silver gel particles) is improbable. In this connection it is of interest to note H. P. Stevens' observations[95] on the rapid (and reversible) change of certain rubber sols into gels on exposure to light, while to the writer it seems inconsistent of Lüppo-Cramer[96] to attribute the fogging action of certain basic dyes and neutral salts to the neutralisation of the negative electric charges on the silver amicrons supposed to be formed in the ripening process and yet to deny the possibility of light bringing about the developable condition by the removal of these electric charges.

M. Volmer[97] assumes that by the action of light a change in the silver bromide grains arises at individual points, resulting in differently attached silver atoms, while Sheppard and Trivelli[98] suggest that "some degree of migration and oriented concentration of the silver cations will occur in the silver halide crystal lattice which will favour the essential photochemical change, i.e., $Br'.Ag \rightarrow Br \times Ag$; in words, the passage of an electron from a bromine ion of the lattice to a silver ion"; they promise to discuss the energy relations later. The crux of the problem lies in the deficiency of energy for the effects produced, and in this respect it is on all fours with the difficulties discussed by Prof. O. W. Richardson[91] in his recent Presidential address to the British Association.

Theory of Development.

In March, 1920, the writer[98] called attention to the catalytic nature of the process of chemical development and pointed out the possibility that the effect of a reagent which apparently "destroyed" the latent image might in some cases be due to "poisoning" of the catalyst formed by light instead of its removal by solution or transformation into a new chemical compound.

The catalytic character of the development process forms the theme of the paper by M. Volmer[97] cited above. He emphasises the difficulty of accepting the older idea underlying the silver germ theory of the latent image, according to which there was no essential difference between chemical and physical development except in the origin of the deposited silver, the original nucleus in either case growing by accretion as the silver gets thrown out from a supersaturated solution.

On the catalysis theory of chemical development, however, the silver bromide grains are rapidly reduced *in situ* as a result of contact catalysis, the processes of solution, reduction to silver, and its deposition being accomplished without bringing into play the transportation of supersaturated silver solutions outside the ambit of the individual grain. A paper by A. Steigmann[99] also clearly brings out the distinctions between the two modes of developing a latent image.

Sheppard and Meyer[100] have previously advanced the opinion that reduction of the silver bromide grain is preceded by adsorption of the reducing agent and takes place in the breakdown of this adsorption complex, the process being accelerated or initiated by the latent image as silver nucleus. In the paper already cited this is amplified.

In the light of the accelerating effects already referred to (of phenosafranine on quinol developers and the mere dilution of some other developers) it is clear that differences in the initial rate of attack, on which the old arbitrary distinction between "slow" and "rapid" developers was chiefly based, are a very uncertain index of the relative energies of different agents. While we must admit the formation of more easily reducible adsorption complexes in the cases above mentioned, and in many other similar phenomena, some unpublished experiments of the writer's show that exposed plates bathed for 1 minute in 1 : 1000 neutral solutions of Chrysoidine or Patent Blue are developable only with extreme slowness in most developers, thus demonstrating the possibility of "poisoning" the catalytic activity of the latent image by the formation of an adsorption complex with the silver halide of quite the opposite character. In these cases also the effect varies in degree with the reducing agent employed and is sufficiently powerful with quinol and some substituted quinols to make development practically impossible. Removal of the dye by prolonged soaking in suitable baths (weak acetic acid for Chrysoidine and weak alkali for Patent Blue) restores the capacity for development.

That the catalytic activity of the latent image may be poisoned similarly by mercuric chloride is suggested by A. St. H.[101] to account for the "destructive" action of this salt when intensification of the latent image might have been expected.

In connection with catalytic reactions of this kind, it would be well worth while to investigate in a scientific and quantitative manner the well-known catalytic accelerating actions of traces of lead, bismuth, and mercury salts in the development of cold-bath platinotype paper, while the extraordinarily powerful poisoning action of tartar emetic on this development reaction (writer's observation, not previously published) is of considerable interest.

E. C. C. Baly and his co-workers[102] have published two important photochemical papers during the year, the first dealing with the mechanism of the combination of hydrogen and chlorine on illumination, and the second with the photo-synthesis of formaldehyde and carbohydrates from carbon dioxide and water. In the former paper strong arguments are adduced in favour of the view that the cause of the considerable deviation from a simple proportional relationship between the reaction velocity and the light-intensity is due to the re-absorption by the reactant molecules (uncombined chlorine and hydrogen) of the energy radiated by the hydrogen chloride in process of formation, with the result that many more of the former become activated than would otherwise be the case. In this, and more fully in the second of the above-mentioned papers, a new hypothesis to account for photocatalysis (colour sensitising) of a photochemical reaction is suggested. According to Baly a photocatalyst must contain the same elementary atoms as the light-sensitive substance or must form a compound or complex with it, but although he states that the sensitisation of photographic plates to red and yellow light can probably be explained on these lines he does not discuss the subject further. At present we have no real foundation on which to build up a theory of colour-sensitising for we do not know what factors are indispensable. Most workers believe that there must be some sort of union or adsorption between the dye and the silver halide, but it is evident that it may be a very loose connection since the considerable blue-sensitiveness conferred on silver chloride by Auramine is readily removed by washing out the dye with water only. Baly's views on this subject are far too general in character to be of any assistance to photographic chemists at present in the search for efficient sensitisers.

It has now become almost impossible for any one worker in photographic science to appreciate at their true value, or even to follow closely, the advances being continually made in the many fields of inquiry from which photography daily draws fresh inspiration, but if this report achieves its purpose, even in a minor degree, it cannot fail to indicate something of the diversity, difficulty, and fascination of the subject.

GERMAN SCIENTIFIC INSTRUMENTS.

Importation of Optical and Photographic Goods.

The Committee set up by the Board of Trade to inquire into the importation of optical instruments, including cameras, from Germany, and the desirability of imposing an additional duty under the Safeguarding of Industries Act, was concluded on Monday last, June 19. The two previous meetings have been reported in the "B.J." of May 19 and June 9. Sir Henry Rew again presided, and Sir Arthur Colefax led for the complaining parties, and Mr. T. W. H. Inskip for the parties resisting the application. The meeting of the Committee was held in the Old Hall of Lincoln's Inn, and the great picture by Hogarth, representing "Paul before Felix," looked down upon all concerned.

At the outset, Mr. Inskip, on behalf of those resisting the application, called evidence from Major A. G. Church, general secretary of the National Union of Scientific Workers, who stated that his union had circularised various bodies with a view to investigating the complaint that the effect of the Safeguarding of Industries Act, the Dyestuffs Importation Act, and the German Reparation (Recovery) Act had been to increase the costs of research. He gave particulars of some researches which had been delayed or abandoned, and claimed generally that the Safeguarding of Industries Act, as at present framed and operated, was hindering and hampering those very activities of the nation which were vital to its industrial supremacy and its security. The supply of glassware was in many respects still very imperfect. Porcelain ware often exploded with heat, and the glass apparatus obtainable was often not properly annealed, not uniform in character, and of the wrong shape. The large Dewar vessels, which were urgently required, were unobtainable in this country. No great difficulty was experienced in obtaining the commoner types of instruments, such as microscopes and balances, though the quality was not uniform.

Mr. S. Segal gave some evidence, the purport of which was to urge that every article coming from Germany should be listed in pounds sterling, not in marks, and then, he said, the British manufacturers would be protected. A member of the Committee pointed out that it would still be possible for German manufacturers to manipulate the prices in their catalogues. Goods of well-known makes, with good reputations, such as Zeiss, Goerz, and Busch, were being improperly imported at extremely low prices, and there was only one remedy for this, namely, importation at the manufacturers' catalogue prices. There were not more than a dozen well-known makers in Germany, and each port should be furnished with manufacturers' catalogues, or the Germans should be made to declare that the goods were sold at catalogue prices, and in this way the British manufacturer would be protected against the influx of German articles at such low prices as some of the importations to-day.

Some rebuttal evidence was then called by Sir A. Colefax. Mr. Conrad Beck stated that a Zeiss microscope which corresponded to a British-made microscope, sold in this country for £30 10s., could be purchased retail in a shop in Germany for £11 2s. 10d., and even with the reparation duty added, the price was only £13 16s.

Mr. Watson Baker put in a recent letter in which 100 pairs of Zeiss prism binoculars, 6 × 30, silver mounted, were offered to the trade at £6 per pair delivered in London. In another letter of earlier date (June, 1921), 5,000 pairs of Zeiss field glasses, 8 × 24, guaranteed absolutely new, were offered at £4 each c.i.f. London. Asked whether he thought the German manufacturers were trying to get their goods on the market at the undercutting prices, or whether, as one previous witness had suggested, they were doing their best to stop the practice, he expressed the view that they were indifferent.

Mr. A. J. Denniss, works director, Houghton-Butcher Manufacturing Co., contested some statements made by Mr. Peeling at the previous sitting. It had been said that there was no British camera competing with the C.D.V. Goerz; there was such a competitive camera in the shape of the Newman and Guardia "Sibyl." Mr. Peeling had said that the Houghton-Butcher firm made a great many more plate cameras than film cameras. The witness handed in an analysis of the output of his firm for the years 1913, 1914, 1920, and 1921. In 1913 the total output of roll-film cameras was 56,175, and of plate cameras 22,514, in 1914 the total output of roll-film cameras was 40,687, and of plate cameras 22,481. The figures for the later years were not stated in public, but the ratio at the present time was just over six roll-film cameras for every plate camera produced. Mr. Peeling had stated that the British manufacturers did not produce lines which were in popular favour. He could only think that Mr. Peeling had made that statement out of his ignorance concerning British makes. Mr. Peeling had also referred to French and American competition. French competition was negligible, and American competition was outside the province of the Committee. Mr. Denniss went on to say that Messrs. Zeiss were now giving their agents commission on quantities sold, and not on values, a reversal of their former practice. This went to prove that they were contemplating a considerable reduction in price.

Mr. Inskip said that he was informed that the bonus was on the number sold, and the discount on the value.

Mr. Denniss went on to remark that at the previous hearing, while Mr. Atha, Messrs. Zeiss' agent in this country, was giving his evidence, a very high official from Carl Zeiss was sitting behind him, who could have thrown light on some of the questions which were described as technical works details, had it been desired that such information should have been supplied. Mr. Peeling had also stated that there was no justification for the British camera being priced so high. But the house of Goerz, for which Mr. Peeling was agent, was identified with the Goerz-Anschutz camera, perhaps the best-known Press camera in the world, and when the war broke out, this camera being unprocurable, a British Anschutz of identical build was brought out, and, fitted with an $f/4.5$ lens and three dark slides, was sold for £30 10s., whereas the corresponding German camera was sold for considerably less—namely, £25 2s. 3d. —which suggested that those concerned for the Goerz productions thought that there was some justification for a camera being sold in England at a higher price. Mr. Denniss added that his firm was not at all antagonistic to these agents for German houses; they were only distributors, and their output was such that they were not really competitive at all. But his firm had its own intelligence department, and he believed that the policy which German manufacturers contemplated was direct sale in this country, and that presently, by the institution of London houses of the German firms in question, the agents would be thrown overboard. Mr. Peeling, again, had suggested that the Houghton-Butcher firm was over-capitalised. Mr. Denniss showed that its turnover was over a million in 1919, and nearly a million and a half in 1920. With regard to the evidence of Mr. Hunter, who had said that certain German cameras got their leather from Nottingham, it was only the leather for the bellows which was so obtained, the other parts not being real leather, and the average cost of leather for making the bellows for a quarter-plate camera was only 9d. It was not his allegation that German cameras were sold at a price below the cost of production, but simply that the German workman was paid in marks the equivalent of 4d. an hour, which made proper competition impossible. He produced a Contessa-Nettel camera, sold in the ordinary way at £2 12s. 6d. at a London stores, and embossed with the name of the stores.

Mr. Inskip said that this camera was supplied to the stores in question by the agent for these German goods, and the reason that the price was below what had been stated for this line of cameras was because the lens was of a less expensive type.

Mr. Denniss said that it was of the same aperture as the others, and the test of a lens was the aperture.

Further rebutting evidence was called by Sir A. Colefax with regard to drawing instruments and ophthalmic lenses, and then the taking of evidence was concluded. Sir A. Colefax and Mr. Inskip addressed the Committee, the one on behalf of the applicants and the other on behalf of those resisting the application. The former, after reviewing the evidence, maintained that a case had been made out for additional duty, and the latter urged that what was complained of, so far as it had any substance at all, was due to temporary conditions, such as the liquidation of accumulated stocks during the war.

The decision of the Committee will be made known in due course.

Edinburgh Photographic Society.—The following changes have been made in the officers:—Mr. McKechnie retires from the presidency in rotation, and is succeeded by Mr. E. F. Spaven; Mr. G. Massie retires from the secretaryship, after long service, and is succeeded by Mr. R. S. Galloway; Mr. N. Ramsey McPherson has resigned the treasurership to take up an appointment in Melrose, and is succeeded by Mr. T. A. Mowat.

A SPECTACLE LENS FOR SOFT-FOCUS EFFECTS.

(A note in "American Photography.")

Possibly this article will be useful to those pictorialists who wish to obtain soft focus effects, but who do not feel that they can afford to pay the price which semi-achromatic lenses usually sell for. Then, too, many advanced workers, who perhaps own one lens of this type, would like several of different focal lengths, which could be placed as desired in the same lens tube.

Of course, it must not be supposed that such a lens as the one about to be described will produce the same effects as the high-priced lenses which are now on the market, but anyone who experiments with this lens will be surprised with the pleasing results obtained with it.

First, procure from an optician or dealer in optical goods a spectacle lens, described as Meniscus (round), 47 millimetres focus, plus 4.50, curve 0. This will cost very little; the writer purchased one, several years ago, for 25 cents each, but they may cost somewhat more now.

These lenses come in all focal lengths, so the pictorialist, with little expense, may have quite a variety, but the one described is nine-inch focus, and perhaps a good one for average work.

Having got the lens, however, the next thing is to mount it in a shutter or tube; it may be that you have an old one which will answer this purpose, but if not, a suitable one can be made of brass or tin, or even cardboard. The tube made and used by the writer

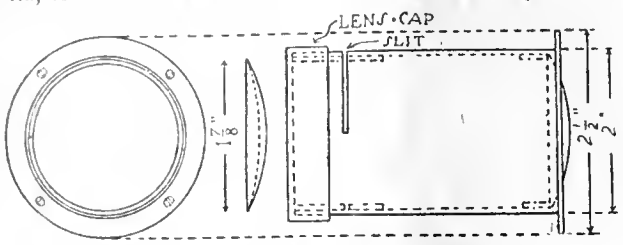

Fig. 1.

is of tin, and, while not as nice looking as brass, is very durable. Do not let the matter of a lens tube prevent you from fitting up such a lens, as a cardboard one will answer very well, and costs nothing but the time of making it.

The inside of the tube should be $1\frac{7}{8}$ ins. in diameter, or just large enough for the lens to slip in. A slot must be sawed or cut crosswise, and half-way through the tube, in which the stops or diaphragms can be slipped.

At the back of the tube a flange $2\frac{1}{2}$ ins. in diameter should be fastened, to hold the tube to the lens-board. The inside diameter of the flange should be $1\frac{3}{4}$ ins., or smaller than the diameter of the lens, so as to keep it from coming out of the back of the tube. The lens is now placed in the back of the tube with the convex side out (fig. 1), and a ring of flexible cardboard is glued in to hold it in place. A ring of cardboard is glued in from the front of the tube to the diaphragm slit, and another strip about $\frac{1}{2}$ in. wide is glued on the other side of the slit, thus leaving a small space, which holds the diaphragms in place. The interior of the tube is now painted dull black, or lined with black velvet, to reduce reflections.

Some diaphragms will be needed, and two or three will be sufficient. These are made of thin metal, such as brass or tin, preferably, but can be made of Bristol board. The focal length of the lens described is approximately 9 ins., and it should cover a 5 x 4 or 7 x 5 plate. The lens at full opening works at about $f/5$ or one-fifth of its focal length, which is rather fast; it gives a very soft image. The other diaphragms can be $f/6$, with $1\frac{1}{2}$-in.

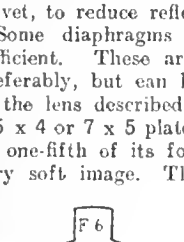

Fig. 2.

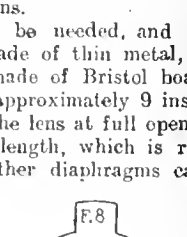

Fig. 3.

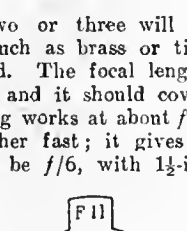

Fig. 4.

opening, $f/8$, with $1\frac{1}{8}$-in. opening, and $f/11$ with slightly more than three-quarters of an inch opening. These are rough measurements, but are accurate enough for practical purposes.

If you are using a lens larger or smaller than the one described, and do not know the focal length, focus sharply on some distant object, and the distance from the lens to the ground-glass will be the focal length. Then divide the focal length by the number of the stop wanted, and the result will be the size of the opening. It is not advisable to use an opening smaller than $f/11$ if soft pictures are wanted. The diaphragms should be painted dull black and marked with their f numbers. Figs. 2, 3 and 4 give the size and shape of the diaphragms. Should you not have a shutter that will fit your lens tube, a lens cap must be made of cardboard and painted dull black inside.

This lens can only be used successfully with a camera which has a focussing screen. It cannot be used on Kodaks, or fixed-focus box cameras, as to get the desired results the image must be focussed on the ground-glass. It must be noted, and this is *very important*, that as the lenses are not corrected for colour, after focussing, and before the exposure is made, the ground-glass *must be moved towards the lens*, about 1/40 of the focal length of the lens, or in this instance from $\frac{1}{8}$ to $\frac{1}{4}$ of an inch. This allowance must be made, as the blue rays fall in focus somewhat nearer the lens than the yellow and red rays. The writer uses this lens on 5 x 4 plates, and finds that this focal length gives very good perspective, and the negatives enlarge very nicely. Also it was found that with this length of lens tube exposures against the light were satisfactory, and especially so when Eastman Portrait Film was used, as this overcame halation.

With all soft-focus lenses experiments should be made with different openings and the results noted. No one can advise just how such lenses should be used, but a few trials will give the worker an idea of what can be done with them, and having certain results in mind these can be worked out.

It is always desirable to give full exposure, and orthochromatic plates and a ray filter will generally give better results than ordinary plates.

Before closing it would be well to say, if you do not secure the desired results first do not blame the lens, as very beautiful pictures can be produced with such a lens when properly handled.

L. M. A. Roy.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications June 6 to 10 :—

Colour Photography.—No. 16,188. Sensitised plates for colour photography. S. Hall.

Automatic Focussing.—No. 15,910. Apparatus for automatically focussing projected images in photographic enlarging and copying J. A. H. T. Rosewarne.

Colour Photography.—No. 16,060. Devices for production of photographs in natural colours. L. Horst Farbenfilm Ges. and L. Horst.

Pumps.—No. 16,034. Liquid pumps (for mixing chemicals). K. C. D. Hickman.

Electrical Transmission of Photographs.—No. 15,935. Apparatus for electrical transmission of photographs, etc. G. R. Judge and R. A. Storey.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

Apparatus for Developing, Fixing, Toning, Washing and Drying Photographic Films.—No. 174,794 (June 8, 1921). This invention relates to apparatus for treating long exposed photographic films, and has particular reference to apparatus of the kind used for treating long kinematograph films, and comprising flanged drums or rollers arranged in parallel pairs in a series of tanks containing the respective chemical solutions for developing, fixing, washing, etc., and means for conveying the film to and

fro between the pairs of drums or rollers, transferring it from those in one tank to those in another, and finally to a drying chamber in which the film also travels around rollers or drums. In such apparatus means such as a dummy strip or a clip on a conveyor band are usually provided to thread the forward end of a film through the apparatus, and means such as a wiping pad or roller of suitable material such as chamois leather are provided to remove adhering liquid from the film at stages in its travel. Also in view of the variations in length of the film some

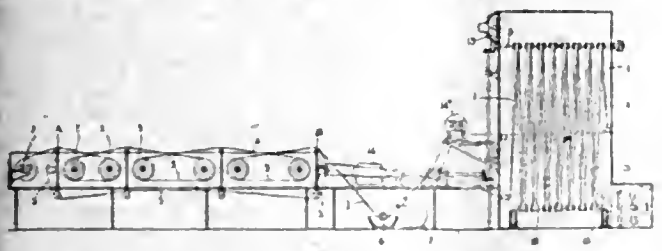

Fig. 1.

loops of the film pass around rollers merely slung or suspended in them, or the rollers are secured to a rotating shaft mounted in resilient bearings.

In one arrangement the lower rollers are mounted on a resilient arm or carrier, with their axes equidistantly spaced and at right angles to the plane of up and down travel of the film between the lower and upper rollers, the axes of the latter also being at right angles to the plane. In another arrangement the upper rollers are co-axially mounted on a shaft lying in the plane of travel of the film and the lower rollers, some of which are resiliently mounted, have their axes at right angles to said plane.

According to the present invention the film, after leaving the developing, fixing and washing tanks and entering the drying chamber, passes over and under upper and lower rollers arranged in two parallel rows, whereof the rollers of the upper row are coaxially secured on a driven shaft extending substantially in the plane of the up and down travel of the film, whilst those of the lower row are mounted coaxially but individually free upon a parallel shaft resiliently mounted to allow for shrinkage of the film. In an alternative construction the lower as well as the upper rollers are secured coaxially to a driven shaft extending substantially in the plane of the up and down travel of the film, but certain loops at intervals instead of passing around a lower roller on the lower shaft pass around idle rollers spaced at intervals between the lower rollers, and each mounted on a spring

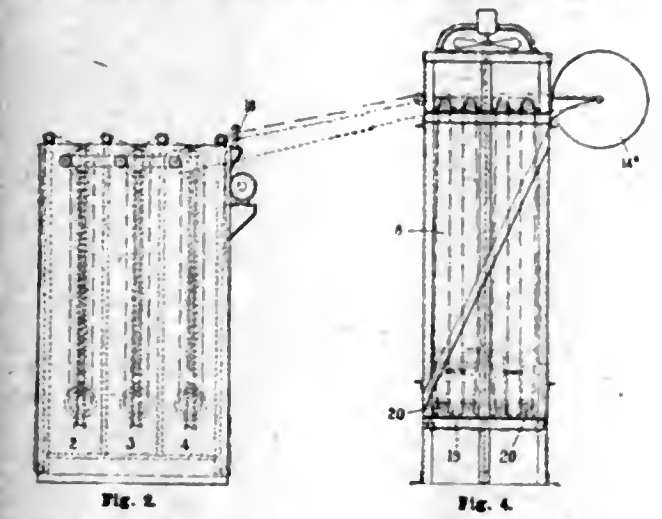

Fig. 2. Fig. 4.

controlled or weighted arm with its axis parallel to the axis of the other rollers.

Fig 1 is a part perspective partly diagrammatic view of one form of the complete plant or apparatus. Figs. 2 and 6 illustrate a modified form of the plant, figs. 2 and 3 being an elevation and plan respectively of the developing, fixing and washing tanks, and figs. 4, 5 and 6 being respectively an end elevation, a plan, and side elevation of the drying chamber.

In fig. 1, the numeral 1 indicates the film to be developed, and 2, 3 and 4 the developing, fixing, and washing tank respectively. In each tank is arranged a pair of parallel horizontal drums which are immersed or partly immersed in the liquid in the tanks. 5 indicates an endless band which passes to and fro between the drums and from one pair to the next and around and over suitable guide rollers outside the tanks. One drum of each pair of drums is driven by a belt from any suitable source of power. 6 represents a bath for alcohol and a roller to guide the film through it. 7 is an air pump to assist in drying the film. 8 is the drying chamber in the upper part of which a row of flanged rollers is fixed to a power driven shaft 9. The film passes over the rollers and hangs between them in long loops. In these loops flanged rollers 10 are mounted freely as shown on a shaft 11 the ends of which are supported on springs to permit the rollers to rise as the film shortens in drying. Pre-heated air enters the chambers by way of the ante-chamber 12 and leaves by way of the fan 13.

In using this form of the apparatus a power source such as the electric motor 14 is started and drives through any convenient form of gearing one drum of each pair of drums in the tanks 2, 3 and 4, also the shaft 9 in the drying chamber, the winding up drum 14^x and such other parts such as guide rollers as may be required. Air heated by the electric radiator 15 is also circulated through the drying chamber 8. The front end of a film to be dried is attached to the endless band 5 at the start point A and is carried and guided by it to and fro between the drums in the developing tank 2 and thence to the fixing tank

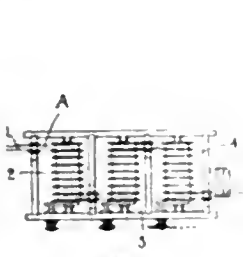

Fig. 3.

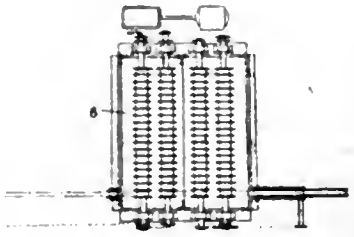

Fig. 5.

3 and similarly to and fro between the drums therein and thence to the washing tank 4, and similarly between the drums therein and over the guide roller 16. The front end of the film is there unclipped from the endless band 5, and is passed under the guide roller in the alcohol bath 6 and thence past the air drying device 7 to the drying chamber. The film is threaded over and under the upper and lower rollers and finally on to the winding up drum 14^x.

Referring to the modified apparatus shown in figs. 2-6, and in particular to the developing, fixing and washing baths 2, 3 and 4 it is to be observed that they are much deeper than those shown in fig. 1, and that the drums of each pair are arranged one above the other instead of side by side. The film passes on to the upper drum at A (fig. 3.) and thence up and down between the drums in the developing bath, thence over a guide roller on to the drums in the fixing bath, then over another guide roller on to the drums in the washing bath, and finally between upper and lower camel hair rotary brushes 18, for removing moisture, to the drying chamber 8. In the chamber 8 the film passes up and down between upper and lower flanged drums in pairs, and finally on to the winding up drum 14^x. The construction in figs. 4 and 6 illustrate a modified arrangement for allowing shrinkage of the film as it dries. The lower flanged drums 19 are arranged in sections on a shaft 20 mounted in a stationary end bearings, and between the drum sections there are freely mounted on the shaft a number of forked arms 21, carrying freely mounted flanged rollers 22 around which the film passes. These arms may be weighted or spring controlled if necessary to provide the requisite tension on the film.

The various rotary parts of the apparatus may be driven by sprocket wheels and chains as represented diagrammatically, but it is to be observed that the film is conveyed throughout its travel without its perforated edge being employed to drag it along, and there is therefore no distortion of the film from that cause

The developing, fixing and washing tanks may be provided with superposed reservoir tanks containing a fresh supply of the necessary liquid, and ball valves or equivalent automatic feeding

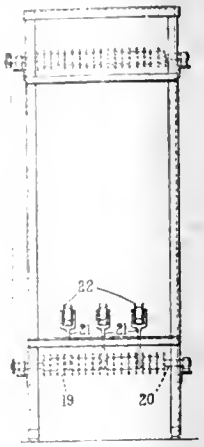

Fig. 6.

devices may be provided to maintain the level of the developing, fixing or washing liquids as the case may be.

In addition to the developing, fixing and washing tanks, a toning tank may if desired be incorporated in the plant.—Paul Louis Barger, 14, Hartington Road, Twickenham, Middlesex.

The following complete specifications are open to public inspection before acceptance:—

Colour Cinematography.—No. 12,408. Optical devices for vision or projection in colours of films with microscopical refractive elements. A. Keller-Dorian.

New Books.

Photography in Colours.—For some years past the text book, "Photography in Colours," by Dr. Lindsay Johnson, has, on the whole, been the best source of information on the various colour processes which at one time or another have reached the commercial stage, and have been used by photographers. A fourth edition (7s. 6d. net), just issued by Messrs. Routledge, might reasonably have been expected to have represented such progress as has been made since the previous edition of the book was published in 1916. A good deal has been done since then, more especially in colour cinematography, which latter Dr. Johnson includes within the scope of his work. Nevertheless, scarcely any attempt has been made to bring the text up to date. Many of the passages have now a curiously antiquated appearance. For example, twenty-four pages are still devoted to the Utocolor bleach-out paper of the late Dr. J. H. Smith. On page 193 Dr. Johnson states that the paper is "now manufactured" by the Société Utocolor, of Paris, although this company had ceased to exist several years before Dr. Smith's death in 1917. A modern treatise on colour photography need not trouble itself much about the bleach-out process, which probably is as dead as Queen Anne. In like manner, in the chapter on screen-plate processes, the reader must conclude that the long dissolved Thames Colour Plate Co. is at least still in existence, for on page 79 it is stated that emulsion-coated colour-screen plates are "about to be placed on the market by the company." We forget exactly how many years it is since the Thames Plate Co. ceased to exist, but it must be seven or eight at least. The fact is that the author has produced not a revised edition but the previous one, with such touches here and there as could be managed without interfering with the make-up of the pages. The only essentially new additions are eight pages printed at the end as a second appendix. It is a pity that the author should not have revised his work upon a scale corresponding with progress in the subject, but the omission is perhaps less to be regretted, inasmuch as a large and full treatise on colour photography by Mr. E. J. Wall is on the eve of publication.

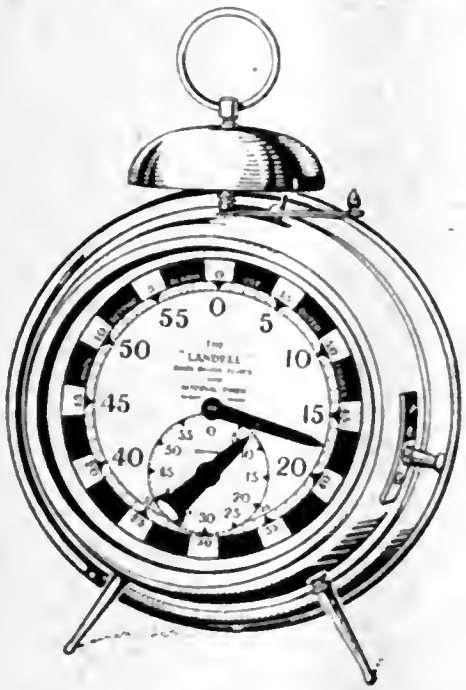
The Cinema Handbook.—It is not easy to imagine that those interested in practical cinematography for purposes other than the eternal drama film will get a better manual of instruction and information than this "Cinema Handbook," just issued by Messrs. Sampson Low, price 14s. net. For the author, Austin C. Lescarboura, took up cinematography as an amateur and ended by making extensive professional use of it. Moreover, he is an editor of the "Scientific American," and thus the work of putting his knowledge into unmistakable and readable English comes naturally to him. His longest chapter is on cinematograph cameras, in describing which he shows an acquaintance with English and French as well as with American models, although the latter get the lion's share of notice. Operation of the camera, developing and printing the negative film and the use of projection lantern occupy similarly highly practical chapters, but perhaps those which are most deserving of recommendation are the ones in which the author deals with the uses of cinematography for industrial and advertising purposes, for the making of films of family, friends or pets, for the production of amateur motion-plays and for many very different educational purposes. Progress in the application of the cinematograph in these directions continues to be slow. The vulgarities of the cinema theatres still dominate the field. Nevertheless, there are signs that schools, colleges, churches, factories, commercial establishments will use cinematography upon a scale at present undreamt of. Mr. Lescarboura does not hesitate to declare his belief that ultimately these uses will overshadow the theatrical stuff, and his manual is written for those who wish to make themselves proficient—for the teacher, traveller, engineer and, we would add, the professional photographer. The latter, technically and commercially, has the advantage over most other classes in ability to make use of these opportunities when they arise, and he should at least not omit to qualify himself by drawing on the stores of knowledge in this book. The many illustrations and diagrams add to the value of the work, which, moreover, is written in a bright, clear style that makes reading a pleasure.

Photographic Chemicals.—Following the brief mention in our issue of June 2 of a French manual on photographic chemicals, the publishers, MM. Charles Mendel, 118, Rue d'Assas, Paris, kindly send us a copy. It is "Les Produits Chimiques Purs en Photographie," and the author is Dr. Camille Poulenc, who, we presume, is a member of the renowned chemical firm of this name. The volume, in the course of 150 pages, gives practical information on the chemical substances used in photography, that is to say, brief particulars of their properties as regards solubility in various solvents, stability, tests, impurities, and, in some cases, methods of estimating purity. For those who read French no more useful volume for information regarding "photographic chemicals" can be desired. In France the price is 5 francs, subject to a surcharge of 100 per cent. in the case of copies exported to England.

Paget and Rajar Competitions.—Two series of competitions for amateur photographers have just been started by Messrs. Amalgamated Photographic Manufacturers, Ltd. One is for prints on Paget self-toning paper from any negative, film or plate, of any subject taken in any camera. The other is for prints on any paper from negatives on Rajar roll film. In each competition prizes, ranging from £5 5s. to £1 1s., will be awarded each month, together with consolation prizes. Entries should arrive at Department 8, A.P.M., Ltd., 3, Soho Square, London, W.1, on or before the last day of each month.

New Apparatus.

THE LANDELL DARK ROOM CLOCK.—An improved model of this clock, which we reviewed in our issue of October 21 last, has been introduced by Messrs. Lingwood & Lowen, 10, Chadwell Street, London, E.C.1. The improvement consists in dispensing with the separate small dial for the alarm. The latter is now set by means of the minute hand on the large and more easily read dial, an outer



reversed numbering of this dial being provided, as shown in the drawing. The large dial thus serves for setting the alarm to ring at the expiration of any period from ¼ minute to one hour. It also marks off minutes, whilst the smaller dial records seconds. The new model, like the former one, is evidently very well made, and is sold at the same price, viz., 25s.

ROENTGEN SOCIETY.—The following officers and members of Council have been elected for the session 1922-1923:—President, Sir Humphrey Rolleston, K.C.B. Vice Presidents, Prof. Sir Wm. H. Bragg, K.B.E., F.R.S.; Prof. Sir Ernest Rutherford, F.R.S.; A. E. Barclay, M.A., M.D. Hon Treasurer, Geoffrey Pearce, 33, Newton Street, London, W.C.2. Hon. Secretaries, E. A. Owen, M.A., D.Sc.; Russell J. Reynolds, M.B., B.S. Hon. Editor, G. W. C. Kaye, O.B.E., M.A., D.Sc. Council, Cuthbert Andrews, G. B. Batten, M.D., A. E. Dean, Kenelm Edgcumbe, N. S. Finzi, M.B., F. L. Hopwood, D.Sc., F. Hernaman Johnson, M.D., C. E. S. Phillips, O.B.E., Prof. A. W. Porter, D.Sc., F.R.S., Prof. A. O. Rankine, O.B.E., D.Sc., Sir Archibald D. Reid, K.B.E., C.M.G., R. W. A. Salmond, O.B.E., M.D.

HOUGHTONS' PROFESSIONAL CATALOGUE.—A new edition of their catalogue of professional requisites has just been issued by Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C.1. Its contents embrace the materials and appliances for portrait studios from cameras for indoor and outdoor work to such items of stationery as transparent envelopes and postal wrappers. Lenses, studio shutters, enlargers, backgrounds, screens and reflectors, studio furniture and accessories, and a great variety of mounts figure in these well-illustrated pages. Among the items of equipment notable from the mechanical standpoint are the very efficient rotary bevelling machine, the Houghton rotary print drying machine, and several patterns of printing boxes. The prices exhibit considerable reductions in many cases. Every professional photographer will want to have one of these catalogues at hand, and can obtain one on sending his trade card to Messrs. Houghtons.

Meetings of Societies.

SUNDAY, JUNE 25.
Willesden Phot. Soc. Outing to Chesham.

MONDAY, JUNE 26.
Southampton C.C. Print Competition. Portraits and Figure Studies.

TUESDAY, JUNE 27.
Bournemouth Camera Club. "Oil Finishing Bromide Enlargements." H. T. Davey.
Hackney P.S. "Personality in Pictorial Photography." E. Brooks.
Manchester A.P.S. R.P.S. Affiliation Competition Prints.

WEDNESDAY, JUNE 28.
Bournemouth Camera Club. Outing—No Man's Land.
Rochdale A.P.S. "Colour Photography." H. Dawson

THURSDAY, JUNE 29.
Hammersmith Hampshire House Phot. Soc. "Carbon Enlarging." M. Watson.
Sheffield Phot. Soc. Outing to Wadsley Common.

SATURDAY, JULY 1.
Edge Hill Camera Club. Outing—Liverpool Docks
Edinburgh Phot. Soc. Outing to Hopeton House.
Exeter Camera Club. Outing—Stoke Canon to Thorverton.
South Glasgow Camera Club. Outing to Cathkin Braes.

ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held Tuesday, June 20, the President, Mr. W. L. F. Wastell, in the chair.

Mr. Edward Peake, formerly of Norwich and now of Cambridge, delivered a lecture on "The Norwich School of Painters," in which he dealt especially with the art of Crome and Cotman, and dwelt at some length upon the real effect it had had upon pictorial photographers in East Anglia, calling into existence a "school" which likewise delighted in the interpretation of open landscape.

On the proposition of Mr. W. B. Ferguson, seconded by Mr. Dudley Johnston, a very hearty vote of thanks was accorded to Mr. Peake for a most eloquent address.

CROYDON CAMERA CLUB.

Mr. A. E. Isaac, an original and popular member, was inveigled by a secretary without appreciable conscience to expound on the "Slide Rule." The attendance might have been better, doubtless due to a sudden change in the weather.

Quite interesting was a preliminary sketch of the gradual evolution of this essentially British instrument. Next came on the scene a gigantic home made model, and the lecturer, with back to his audience, talked learnedly to himself for a considerable time. The conversation included an explanation how the figuring had been set out, mostly lost to the members, who could not see a number.

Gradually an atmosphere of levity permeated the proceedings, and the fun, if not wit, became fast and furious when Mr. Isaac nearly smashed a window by pushing the slide out to its fullest extent. Simultaneously a cube root got adrift, ultimately extracted with some difficulty, apparently, from the floor.

At intervals Mr. Scott astounded everybody by readily furnishing complex ratios, till it was discovered he was possessed of Wrapson and Gee's "book of the words." Personally, he regarded the lower notes of a slide-rule as fairly safe, but the higher were undoubtedly squeaky. Valiant defenders of this curious musical instrument were next found in Messrs. Purkis and Jobling. On the other hand, Mr. Harpur said not for nuts would he allocate his annual balance sheet to the sliding fraternity.

The president, Mr. J. Keane, refreshed by a prolonged nap, conveyed in eloquent terms the thanks of all for a most entertaining evening to Mr. Isaac, who by this time had fully appreciated the humour of the situation. If memory rightly serves, he gave the lecture on a previous occasion at the club, and it is essentially one that will bear further repetition—elsewhere.

During the interval Mr. Ackroyd showed an ingenious camp armchair. Two looped cords are passed over the feet, the other ends terminating in a fabric band as a rest for the back (at the expense of the feet). It gives to the occupant a striking

resemblance to a trussed fowl, and although alleged to be very comfortable, evidently does not afford luxurious ease out of harmony with the simple life.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of Council was held at 35, Russell Square, on Friday, June 9. Present: Messrs. Marcus Adams, A. Basil, A. H. Ll. Chapman, T. Chidley, A. Corbett, C. F. Dickenson, W. E. Gray, R. Haines, G. Hana, W. Illingworth, H. Lambert, R. N. Speaight, F. Wakefield, A. Swan Watson (President), W. Wedlake, with Alfred Ellis (Secretary) and J. Griffiths (Editor). Mr. A. Corbett took the chair.

Arising out of the minutes, the Secretary reported upon a transaction between a member and a frame maker, the latter having threatened proceedings. After seeing the frame maker and the record of the transaction, he (the Secretary) advised that the photographer's best course, in view of the expense of coming to London to defend the case, was to pay the sum demanded. This action was endorsed.

With regard to a member's complaint that the reproduction of a photograph in a certain paper had not been paid for, the Secretary said that the firm complained of was surprised that any charge should be made for a reproduction in a paper that was given away to their customers, but he persuaded the complainant to hand over the matter to the Association's solicitor, with the result that a demand was made for the fee and costs, and this was promptly paid.

With regard to some plates, of which a member had complained as being useless, Mr. Basil reported that he had tested an unopened packet, and he thought that all that was wrong was probably that they had been in stock for a long time. They showed only a little fogging. The Secretary said that he had advised the member to try them again under different conditions.

The Secretary reported that another member had complained that he gave an order for enlargements which were not supplied, and, as a result of correspondence, the member had had his money returned to him. He had promptly paid up his subscription for a year in advance.

There was a brief discussion in regard to a case in which a member had supplied photographs with a background of which the customer complained. Behind a young girl on horseback appeared a board pointing to a saloon bar. The photographer blocked this out, but after some time the customer refused to pay. The solicitor was consulted, and thought that in an action the photographer would stand little chance, so the member had been advised to let the matter drop. The Council examined the photographs, and endorsed the action taken.

Correspondence was read regarding a complaint by a member that a water-coloured photograph, 30 × 20 in., properly protected, was damaged in transit on the railway, arriving in a damp condition, and spoiled beyond repair. The railway company declined to admit the claim. The Association's solicitor had pointed out that the parcel was sent at owner's risk, which meant that the carrier was not liable unless some wilful misconduct of a servant of the company could be proved. The Secretary said that he had written to the member pointing this out. The moral appeared to be that the sender should declare and insure all valuable goods when sending by carrier. Probably a package of wet fish or ice was placed on this parcel in the luggage van. There was no reason why the member should not ask for compensation as an act of grace. The Secretary's action was endorsed.

Mr. Hana submitted to the members a schedule of prices for commercial work which he had drawn up after exhaustive inquiry. Mr. Illingworth also gave some information, and it appeared that the charges he showed were almost identical with those submitted by Mr. Hana. The latter was thanked for the trouble he had taken, and was asked to supply copies of the schedule to members of Council, so that suggestions might be made and an average decided upon as soon as possible.

Mr. Wakefield reported that the necessary preliminaries with regard to the Congress had now been arranged with the L.C.C. authorities regarding the precautions against fire. In reply to questions, he said it was proposed to charge exhibitors about 5s. per square foot of space. It was found impossible to allow exhibitors to erect their own stands, as the hall was not suitable for that purpose. Mr. Speaight proposed that an emergency meeting of the Council be held as soon as possible, in order to proceed quickly with this matter, and this was agreed to.

Mr. Adams reported that he had received a letter from Mr. J. C. Abel, of the P.A. of America, expressing thanks for the splendid collection of pictures sent to America, which was now on its way to Seattle, Washington, for exhibition there. The Council heard with much satisfaction that Mr. Pirie Macdonald would come over as official delegate to the Congress, and that Mr. Abel hoped to accompany him, and to send a good collection of American work for exhibition. Mr. Adams also said that he anticipated good contributions from California, as well as from European countries. Mr. Speaight added that, from inquiries he had made in Belginm, he believed there would be a good collection from that country.

Mr. Swan Watson and Mr. Haines also reported that they had received fraternal letters from Mr. Abel, who expressed gratitude for the friendly spirit shown by the Association.

Reporting with regard to the programme for the Congress, Mr. Haines suggested that a programme committee should be appointed, to consist of the Secretary of each existing committee. This was agreed to, and it was left to Mr. Haines to convene a meeting.

The President and the Secretary reported upon their visit to the Master Photographers' Association of Lancashire, describing the hearty welcome given to them, and the general interest of the occasion. Mr. Marcus Adams was thanked for sending to this Convention a collection of pictures for exhibition.

The Secretary reported that the same member who had just received payment in a case taken up by the Association had now complained of trouble with a printer of postcards. The postcards having been examined, it was agreed that they would not enhance the member's reputation. The matter was left in the hands of the Secretary.

The Secretary reported that there had been two resignations. Two applications for membership were received, and found to be in order.

After the business of the meeting, which lasted over four hours, was concluded, the President said that, as a member of the Council, he must express his great admiration and appreciation of the enormous amount of time and trouble taken by the London members of the Council in carrying on the work of the Association, and he should like to have that appreciation recorded; whatever the country members of the Council might have to expend in time and money by attending the monthly meetings, it could in no way be compared with the work that was being done day by day by the other members of the Council.

Commercial & Legal Intelligence.

NEW COMPANIES.

British Studios, Ltd.—This private company was registered on June 10, with a capital of £200 in 1,000 ordinary shares of 1s. each and 150 preference shares of £1 each. Objects: To carry on the business of photographers, photographic dealers, artists, picture framers, etc. The permanent directors are:—C. H. Sheffield, The Cottage, Langston, Havant; Mrs. M. Sheffield, The Cottage, Langston, Havant (both directors of Stanley Gordon, Ltd.), with £750 and £500 per annum as remuneration. Registered office: 18, Russell Street, Southsea, Hants.

W. M. Bell & Co., Ltd.—This private company was registered on June 13, with a capital of £2,000 in £1 shares. Objects: To acquire the business carried on by L. S. Woolf, trading as "W. M. Bell & Co.," at 2, Malvern Road, Kilburn, and to carry on the business of opticians, dealers in photographic materials, optical instruments, etc. The first directors are:—J. C. McCorqnodale, 63, Glenmore Road, N.W.3 (managing director); T. H. James, 179, Lynton Road, Bermondsey, S.E. Qualification: Five shares. Remuneration of managing director, £312 per annum. Registered office: 2, Malvern Road, Kilburn, N.W.

Film Printers (1921).—Particulars of the Film Printers (1921), Ltd., were filed on June 6. The capital is £15,000 in £1 shares (11,000 12½ per cent. participating preference, and 4,000 ordinary). The company was incorporated in Isle of Man on November 17, 1921, to carry on the business of printers of cinematograph films in either black or coloured monochrome, or in tints, natural colours or any other process, photographers, etc. The British address is The Hyde, Hendon, where E. B. Smith and R. W.

Wicks are authorised to accept service of process and notices. The directors are: L. J. Hibbert, 51, Whitworth Road, South Norwood; S. E. and E. B. Smith, 16, Fitzroy St., W.1. The Somerset House file number is 2.107F.

News and Notes.

ILFORD LECTURES.—Messrs. Ilford, Ltd., have a few vacant dates for lectures and demonstrations during the next session. A list of subjects will be forwarded to society secretaries on application.

PRIZES FOR MOUNT DESIGNS.—Messrs. Houghtons are offering prizes of £10, £5, and £3, as well as consolation prizes of £1, for designs in portrait mounts, with or without covers. The competition closes on August 31 next.

MICROSCOPES AND PHOTO-MICRO CAMERAS.—The City Sale and Exchange, 81, Aldersgate Street, London, E.C.1, send us a revised catalogue of the renowned manufactures of the Italian firm of Koristka. The list includes several patterns of photo-micrographic camera. The prices show many substantial reductions.

OF INTEREST TO PROFESSIONALS.—Messrs. Kodak, Ltd., have just issued a booklet descriptive of a few of their special lines for professional photographers. Among them are the "Cirkut" panoramic camera, Kodak projection printer, focussing spotlight and "Kodura" and other papers. Obtainable free on application to Kodak House, Kingsway, London, W.C.2.

NEW PHOTOGRAPHS OF MARS.—This week the planet Mars will be nearer the earth than at any time since 1909, at which time Professor Lowell succeeded in obtaining the best photographs of it. Photograhy has advanced during the past thirteen years (writes a Greenwich correspondent), and this week a large party of American astronomers and photographers is going to South America (from which part of the world Mars is seen at its best) for the purpose of getting some improved and up-to-date photographs of the planet and its "canals," and the most wonderful results are anticipated. In our own part of the world, Mars, though a splendid naked-eye object, is rather too low in the sky to permit of detailed telescopic observation or really good photographs of it.

DIRT ON LONDON'S STUDIO ROOFS.—Photographers located in the provioces may learn, from a report of the Medical Officer of Health for last year, of some of the inconveniences their brethren in London met with, and cease to wonder why so many of them go in for artificial light installations. In November last the amount of deposit registered as falling in the City amounted to 18.37 tons per square kilometre, which is equal (estimating the City as having an area of one square mile) to no less than about 47 tons. Of this mass of dirt, approximately 27½ tons were soluble, and 19½ tons were insoluble, and consisted of tar, carbon and grit. During the year the amount of the impurity at noon varied from half a milligramme to six milligrammes per cubic metre of air. This latter figure included times when there was a fog.

PHOTOGRAPHS OF CRICKETING.—The many excellent photographs of cricketers appearing in the Press to-day are a credit to photography, and special mention might be made (writes a correspondent) of the cricketing pictures illustrating the advertisements of Ross, Ltd., and Taylor, Taylor & Hobson, Ltd., in last week's "B.J." Photographers have yet much to learn concerning the picturing of lawn tennis players and footballers, who are usually depicted in the most ridiculous attitudes imaginable. One of the secrets of success is distance, the T.T. & H. advertisement telling us that the operator used a telephoto lens at a distance of 200 yards. Players at football and tennis are usually taken "close up," and from peculiar points of view, and photographers of all sports would no doubt do better if they employed a long focus lens and stood at a greater distance from their subjects.

PHOTOGRAPHING MANSIONS.—A writer in one of the daily papers last week referred to poorness of many aristocratic families living in Elizabethan and other mansions, and gave as a proof of it their attitude towards photographers. Years ago, it was stated, the nobility often refused permission to photograph their pictorial residences and grounds, but to-day photographic firms were actually approached by owners of mansions only too anxious to offer facilities for either film or still work at a reasonable figure. "Only this week," says the report, "an estate in Gloucestershire of 6,000 acres has been on offer. The daughter of the house, making a personal round of visits to photographic firms, has explained that she offers an Elizabethan mansion with an imposing exterior, a 200-year-old pigeon-cot, with accommodation for 500 pigeons, four or five picturesque summer houses, wooded nooks, a lake and a stream, and even two collie dogs."

PORTRAITS IN PHOTOGRAVURE.—We have recently inspected with a good deal of pleasure examples of the work of the Photogravure Company, 21, Farringdon Avenue, London, E.C., a firm owned by Mr. J. W. Beaufort, of Elliott & Fry. For some time past in his own large and important business, Mr. Beaufort has found a growing demand for portraits in photogravure for presentation purposes in numbers, and hence has been moved to assure to himself the means of their production. A photogravure has a character of its own, and when prints are issued of such beautiful quality as those we have seen, photographers generally will be glad to take advantage of the resources of the Photogravure Company. In cabinet size the charge for proofs to the number of a hundred or less works out at little more than sixpence apiece, so that there is the opportunity for the photographer to offer an important customer something wholly distinctive and to reserve a nice profit on the transaction to himself. The company does not intend to cater for the postcard publisher: its specialty is larger work in comparatively small editions. Among the specimens were some exquisite examples of photogravure in colours by hand inking of the plates, a branch of work which the company has wrested from the Continent, and in which it has satisfied the critical taste of publishers of the exquisite French coloured mezzotints. Perhaps no higher testimony could be paid to its craftsmanship.

CHARGES FOR ELECTRICAL ENERGY USED IN PHOTOGRAPHIC STUDIOS.

To the Editors.

Gentlemen,—With regard to the recent case in the King's Bench, fully described in your issue of May 26 last, I have carefully read the subsequent issues and failed to find any further reference thereto.

Perhaps, as the matter is (apparently without their knowing it) of considerable interest and importance to a great and increasing number of photographers, you will allow me, an outsider so to speak, to make good the omission, whether this arises, as it would seem, from the apathy of your readers—a category which, I am reliably informed, includes the whole of the photographic profession—or not.

And, firstly, no praise is too high for the editorial summing-up. It covers the ground so ably and fully, yet withal so succinctly, that it might be the work of both lawyer and electrical expert—and both tempered more than ordinarily with the common-sense of everyday business—that I can do little more than emphasise the importance of the subject to all users of electrical energy, no matter to which industry or profession they may belong, and clothe it in special garb as it appears to one who has had some seventeen years' experience of electrical power generating and supply station work.

I cannot claim any knowledge of the business side of professional photography. Perhaps, sirs, you can tell me whether "art" carries members of that profession above the sphere of such mundane considerations as appertain to business?

Perchance you can induce your contributor, Mr. Pelham Swinton,

to enlighten me, or is it only the "dons" that can afford to photograph debutantes with "five 15,000 candle-power lamps . . . . flowing ties and tortoise-shell spectacles," as described in the evening papers, without counting the cost?

The question has often been put to me: "When did the electrical supply companies first differentiate between 'light' and 'power'?"

This is difficult to answer definitely, as the difference arose by a process of evolution. The St. Pancras Borough Council were certainly one of the first (some thirty years ago) to recognise the necessity for fostering and encouraging daylight use of electrical energy, to enable them to run their generating plant for longer continuous periods per day, thus reducing the cost per unit generated, the interest charges on capital outlay of plant being considerable, lower priced units and other methods of inducement having to be resorted to from the first in order to oust the firmly established gas competitor from the field.

One fundamental difference between the competing gas and electrical undertakings consists in the greater ease and comparative cheapness with which gas can be accumulated in gasometers during what is practically a level rate of production spread over many hours' continuous generation, the main-peak load demand of customers being supplied mainly from this reserve, which means a considerable saving in initial outlay on generating plant such as is occasioned with electricity, and what might be termed a rental charge that has to be covered in the total amount charged to customers in proportion to their rate of use—diversity of time factor.

The law has never been so favourably inclined towards electricity, handicapping it to a great extent in its competition with gas undertakings. Hence, from time to time, we hear of such actions the Long Eaton, Hackney, Ilford, and others as mentioned by the learned Judge.

Now, there are some aspects of the judgment which appear somewhat strange, maybe owing to my not possessing a legal mind.

The learned Judge having stated (*a*) That the station turns out only one kind of energy, (*b*) that the purpose to which the customer puts this energy is irrelevant, and, (*c*) that it is only in so far as the customer's circumstances react upon the supply that he takes—in the matter of load factor, diversity (time in use) and quantity of units purchased—that differences of charge are allowed; the learned Judge then proceeds to assume, without evidence either for or against, that the particular load in question is different from or inferior to the loads of other users who are regularly charged the ordinary advertised "power" rates. This is "palpably out of relation with the facts." I respectfully submit that many users of electrical energy use as high, or even higher, amperage, and use it more intermittently, purchase a smaller number of units, and possess no meritorious features from the point of view of the electrical power generating station (lifts, hoists, vacuum cleaners, sawmills, to mention a few). Yet these are charged ordinary advertised low "power" rate.

I can recollect from my own experience a sawmill which used electrical energy at a rate of some hundred odd amperes, which were intermittently imposed on the generating plant with "rimbrake" jerks; in fact, it was only by considerably strengthening the main fuses that we could maintain the supply to the consumer to enable him to convert into planks the "fallen majesties of the forest" with one fell swoop of many saw blades and many thrusts into their vitals.

The intermittent load under question fades into insignificance against this example, which was at 1d. per unit, if I remember correctly.

Again, the learned Judge says: "Photographers, speaking generally, are not taking current for power purposes under similar circumstances to other manufacturers."

As a fact, the electrical energy demanded and so used by different photographers varies so greatly that it seems impossible to treat them "generally." Speaking specifically, the defendants are using electrical energy under circumstances similar (and more advantageous to the electrical power generating station) to some other users in the immediate vicinity.

Regarding his Lordship's final sentence, which seems irrelevant, "All photographers in the area using this supply have been treated in the same way"—they may have, but have all those photographers treated the electrical power station in the same way—*i.e.*, in the manner in which "they react upon the supply"? One cannot compare the load of those photographers who only use electrical energy when the photographic values of daylight fail, *i.e.*, during the period of maximum or peak load on the generating plant, and those who, like the defendants, use the current all day and every day. On the occasions I visited the studio the energy was in use practically continuously, being shut off at intervals to economise, in view of the threatened 8d. per unit charge, moreover in a basement shut off from daylight.

I might here remark upon a great diversity of opinion among London electrical supply generating station authorities, several of whom seem to be very undecided about what should be charged for electrical energy to photographers, viz. :—

15 areas charge "power" rate.
1 area charges full "lighting" rate.
14 areas not definite; subject to negotiation, probably compromise.

In the defendants' case we have :—

Years 1913-1916—1d. per unit = power rate.
Years 1916-1921—1½d. per unit = power rate (war increase).
May, 1921-October, 1921—8d. per unit = lighting rate.
October, 1921, to date—4d. per unit = query rate.

I wonder how a gas undertaking would fare if it charged initially 2s. per 1,000 cubic feet in 1913, or for comparison in tabular form :—

1913-1916—2s. per 1,000 cub. ft.
1916-1921—3s. per 1,000 cub. ft.
1921, May—16s. per 1,000 cub. ft.
1921, October—under protest, 8s. per 1,000 cub. ft.

Would it help to popularise the use of gas in the present state of business? Putting it bluntly, is the plaintiffs' supply seriously affected by the defendants' method of using the energy, there being so many intermittent users of electrical energy, whose demands would not occur simultaneously?

I am informed that in the provinces a very large majority of the electric supply undertakings charge power rates for photographic users without so much as a quibble.

It is practically impossible to interpret the clause "Under similar circumstances." To be fair to defendants, it seems that all intermittent users of electrical energy should be charged at the same rate, whatever use the energy is put to. If not, the clause "Undue preference" exercises one's mind. Or, in future, are electrical supply charges to be based upon the class of industry or profession? A greengrocer will not make varying charges according to the individual business or profession of his several customers, e.g., by charging 3d. a lb. for apples if for eating *uncooked* as against 2d. a lb. for eating *cooked*; or, again, if a customer eats one apple per hour for eight hours and the other eats the eight in two hours, say. Pardon my putting forth this analogy, under the plea of my endeavour to make the question of electrical supply clear to non-technical minds. Although I run the risk of being dubbed a "heretic" by the electrical generating and supply undertakings, my desires are quite the opposite. I want to see electricity used more extensively, and every effort made to popularise its use.—Yours faithfully,

J. C. Elvy, A.M.I.E.E., M.I.E.S.
Consulting Electrical Engineer.

12, Tavistock St., Covent Garden, London, W.C.
June 19.

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—I was very pleased to see Mr. Ralph Grenell's letter in your issue of the 9th inst., and to read his exposition of the Douthitt System. His letter confirms my original opinion that the system is unnecessarily complicated, and does not agree with my formula for a successful half-tone operating system.

The optical and physical laws upon which it is claimed that the Douthitt system is based are unalterable, but to what extent do they apply to the questions at issue? The optical law applies to the distance of light from copy and to the ratio of camera extension to stop opening, but I fail to see how the physical law applies. Mr. Grenell tells us that the openings in a 100-line screen transmit four times more light than the openings in a 200-line screen. The screen opening cannot transmit more light than it receives from the lens, and, assuming the same stop diameter in each case, the larger screen opening distributes the light over a larger area and forms a larger dot than the finer ruling, but the light transmitted over a given area of the photographic plate is the same in either case, providing that the screen separations are accurately adjusted.

The Douthitt screen separations may be optically correct from the stops used, but I cannot agree to the necessity for smaller stops for

coarser rulings, and the consequently greater screen separation. That the system obtains good tonal gradation with different screen rulings is no proof that it is the only system that will do so; it only proves how much latitude there is in the process. I believe that it is possible to obtain equal gradation from a given copy with a variety of stops with the same screen providing the separation is accurately adjusted to each change of stop, and the same thing applies to different rulings. But why use such a variety of stops when as good gradation can be obtained by much simpler means? that is, with the same stop, exposure and light-distance with all screen rulings from a given copy.

The attempt to make exposure constant with different rulings by varying the light-distance is only another complication. What happens in the case of a coarse screen negative from a large copy outside the radius of the lamps at the close position? It is as well to remember that all half-tone operating is not done with movable arc lamps. In my own case, for example, the whole of the work is done with mercury-vapour lamps that are never moved except in the case of an exceptionally large copy.

My statement as to correct gradation being only possible with one stop is not affected by any dodge that may be resorted to to secure a negative from the unusual copy, because in this case we are deliberately seeking false gradation. I have yet to find any advantage in using more than one stop, even for the unusual copy, but it does not follow that the stop used has the same proportion to the extension as the screen opening has to the separation.

I am glad to see that Mr. Grenell finds that the same laws apply to wet as to dry plate, because I have always assumed that they did, but have not felt sufficient interest to test it out.

My promised article on the diffraction fringes has been held up owing to pressure of other work, but it is well on the way, and I expect to complete it during the next few days, when I hope that it will help to solve some of these problems.

Since writing the above, Mr. Ray's letter has come to hand, and I must express my pleasure to find that the subject is attracting attention. This letter is already much too long, so I will endeavour to reply to Mr. Ray next week.—Yours faithfully,

E. A. Berman, F.R.P.S.

BLUE SCREENS IN COPYING STAINED PRINTS.

To the Editors.

Gentlemen,—I can sympathise with Mr. Milner in his perplexity. I noted this variance with theory fifteen years ago, but may I suggest that he tempers his theory with a little practical experience of the subject in question. It may interest him to know that the ink stain was black, not blue-black, and the use of the phrase, "*somewhat* expected," was due to past experience.

Possibly Mr. Milner did not read my letter carefully, or he would not have jumped to the conclusion that the experimenting in the making of colour screens was an initial attempt at photography. Also he should have been impressed by the particular mention of the choice of screen and the nature of the stain. Neither did I intend the inclusion of "a yellow-freckled cloud" under the heading of "copying."—Yours faithfully,

Brentwood, June 19. C. D. Venning.

SULPHIDE TONING.

To the Editors.

Gentlemen,—Your editorial article on the sulphide toning of bromide prints indicates very plainly that there are still many photographers who do not realise the conditions that are essential for obtaining uniformly successful results. The simple process of toning by first bleaching a print and then treating it in a solution of sulphide should leave nothing to be desired, and, in addition, it should be so certain that failure, or even partial failure, should be impossible.

The subject of sulphide toning is, naturally, too long to discuss fully in a letter, though it would be interesting to write on the conditions necessary for ensuring success. But as I have given considerable attention and devoted a large amount of experimental work to this process, I would like to supplement your remarks by adding a note on a distinctive difference between the single-solution processes and the bleaching and sulphiding method.

The principal difference is the colour of the resulting image. In the single-solution methods the colour is a purple-brown. In your article you describe it as "the standard brown of the carbon printer," this standard brown being essentially a purple brown. Bleaching followed by a sulphide solution produces a pure brown, without any trace of purple, whether the brown be relatively cold or warm. And this purity of colour possesses another advantage, there is a greater transparency of the shadows.

In the modification which I introduced some years ago, by means of which brown-blacks or cold browns were obtained by adding a mercuric salt to the bleaching bath, this purity of colour was still maintained; the colour was always brown or brown-black, and never a purple-brown or purple-black.

Considering the simplicity of sulphide toning, and the richness and quality of its results, it is surprising that any photographer can be found who will admit that it presents difficulties.—Yours faithfully,

Henry W. Bennett.

Ilford, June 17, 1922.

To the Editors.

Gentlemen,—Permit a very humble worker—but nevertheless a practical one—to endorse all you say in your last week's leading article on sulphide toning, and to suggest that the subject be further investigated.

Post-war bromide and gaslight papers do not tone nearly so well by the sulphide (bleaching and darkening) method as did the pre-war papers, and the liver of sulphur, or even the hypo-alum process seems to suit modern papers better than the two-solution sulphide process. In pre-war days I found no difficulty whatever in securing the most pleasing of rich, deep brown tones, but I fail to do so to-day even when I use the same make of paper and formulæ, or, as it would be more correct to say, what are believed to be the same. Some chemicals have, in my opinion, changed somewhat, and many old formulæ require to be overhauled.

We have also different emulsions to deal with, and the present craze for emulsions giving images other than the purest of blacks by direct development, has resulted in emulsions giving images which do not tone so well as one would wish. Obviously the makers pay the greatest attention to the production of a warm-black or brown-black tone by direct development, the toning of the image being quite a secondary consideration.

All makers, I suppose, claim that their bromide or gaslight emulsions will tone well in a sulphide bath, but no maker has to my knowledge produced a paper giving an image specially suitable for toning. And yet there should be a market for such a paper, as sepia-toned bromides continue to be a leading line with many of us, although at present it is rather a "hit-or-miss" method of working.

It is not the directly-developed tone that interests many, but rather the tone obtained in a toning bath, and I for one care not how black, or what shade of black, the developed image is if it will tone well. And as sepia-toned bromides are now a regular line I wonder paper-makers do not help us by giving the matter some extra special attention.—Yous truly,

Ellis D. Owen.

WEDDING PHOTOGRAPHS.

To the Editors.

Gentlemen,—To-day's "Daily Chronicle" suggests that "the ordinary wedding photograph is on the way to becoming a thing of the past." This may be so, but the method I adopted a few days ago may prove of interest.

Receiving an order to photograph a wedding-party I, in addition, took photographs of guests entering the church; the bridesmaids in the church porch; arrival of the bride and her father; a photograph inside the church during the ceremony; and the bride and bridegroom leaving after the ceremony.

The wedding party, and the bride and bridegroom, were photographed afterwards as arranged.

The proofs were mounted in a loose leaf album, together with a photograph of the church, the whole forming an interesting—and I hope an irresistible—souvenir of the occasion.

Such a collection should prove more acceptable to those concerned, and what is so important now-a-days, should bring in a more profitable order.—Yours faithfully,

F. Jenkins.

High Street, Southwold, June 17.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

F. B.—We cannot suggest a better arrangement than that which you sketch. The only thing we should alter is to change the lamps over to the other side of the studio. In nine cases out of ten the left side of the face is better-looking than the right. Your work is quite good, but we should imagine that you are using rather a short focus lens for such large heads. To get good drawing you want at least a 12 inch lens for this size.

E. F.—For whole-plate large heads the best results are obtained with a lens of focal length between 20 and 30 ins., or even longer. There is plenty of room in a 23 ft. studio for the use of a lens of this focus for this special purpose of large heads, but it will be of comparatively little use for anything else. If you want to make, say, cabinet heads in the studio, with the same lens, about 14 to 16 ins. focal length is as long as you can afford to have.

W. A.—Your inquiry is so vague that it is impossible to deal with it within the limits of a letter. Finishing may be done in monochrome with water-colour, oil-colour, crayon or acrograph, and it would require a fair-sized book to describe them all. You can obtain a special catalogue of photographic finishing materials from Winsor and Newton, 37-40, Rathbone Place, London, W.1. When you decide on which process you will adopt we shall be glad to answer any specific questions.

E. D.—So far as we know there is no "paste" which can be used to repair camera bellows. The best way to do this is to extend the bellows as fully as possible, and to cement with Seccotine or similar glue small pieces of silk or shiny black linen inside the corners. A little Seccotine may be rubbed over the ragged places outside, and the surface patted smooth while the glue is damp. If the leather is badly damaged, a bit of thin basil leather may be stuck on where necessary.

K. G.—It is entirely contrary to the custom of the trade that an enlarging firm should put its own name on the enlargements which it makes for its professional photographer customers. You should certainly return the enlargement, pointing out that it is useless to you when mounted with the name of anybody else upon it. There is no particular objection to the word "copyright," but on the other hand you should be the person to decide whether you wish this inscription to appear or not.

P. S.—We think the explanation of the films is that there is a damage in the bellows which is fogging the greater portion of the image by diffused light, whilst the various black lines represent pin-hole images of the sun moved about on the surface of the film. It is quite a common experience that only some negatives out of a spool are fogged in such a case, as it depends upon how long the camera is carried with the bellows extended, and also the volume of light and the position of the sun have an influence.

A. B.—The Vanguard Manufacturing Co., Maidenhead, make an ink for writing on plain glass. They list it in the following colours—black, violet, red, blue and green. They also make a preparation called "Subtralene,' for coating glass to enable writing and diagrams to be drawn with pen and ink or pencil, and they also list what they call "Screenolene," an opaque, quick-drying black varnish, which can be used for the making of lantern diagrams in white lines on a black ground by the use of a needle or other fine stylus.

M. B.—The lens appears to be of the portrait type, and possibly the fault of not giving proper definition at the full aperture, which should be *f*/4, is due to the glasses having been misplaced. The glasses of the front combination are pretty sure to be right, but it is possible that the elements of the back combination have got out of place. The flatter curve of the double convex glass, which comes right at the back of the lens, should be in the rearmost position. The most common mistake made in assembling a lens of this type is for this glass to be in the reverse position, in which case a very much smaller area of field is covered. If adjustment of the glasses does not improve matters as regards giving satisfactory definition you had better send the lens to an optician to be overhauled, *e.g.*, to the Premier Optical Co., 63, Bolton Road, Stratford, London, E.15.

X. Z.—(1) We think your practice as regards hardening prints for avoidance of blistering is quite all right. No doubt the use of alum in the first fixing bath does tend to yellowing of the whites owing to the less perfect removal of the silver compounds from the emulsion. If you get sufficient hardening by putting the alum in the third fixing both, we don't think you can do better than stick to this method. (2) No doubt an enamelled iron showcard will withstand the weather better than anything else. Three firms for these enamelled signs are as follows:—(1) Sam Trenner and Sons, 76-78, Gray's Inn Road, London, W.C.1; (2) Macfarland and Robinson, 76-78, Southwark Street, London, S.E. 1; (3) Garnier and Co., 84, Farringdon Street, London, E.C.4. No. 1 has had experience in making signs for photographers in connection with supplying really nice-looking things for war memorials.

A. W.—Correcting the meanings of your symbols:—

x = extra-focal image distance of object at distance $d + f$, i.e., x is distance of exit node of lens from front focus. When focused on infinity the exit node is f from the image.

f = focal length of the lens (not "extra-focal," which term applies only to image and object distance).

d = extra-focal distance of object, i.e., object is at the distance $d + f$ from the entrance node.

With the above signification of the symbols the formula $x = f^2/d$ is quite correct, since it is simply a transformation of the Newtonian formula $\frac{1}{v} + \frac{1}{u} = \frac{1}{f}$, as is pointed out by Piper on page 45 of the "First Book of the Lens."

If with the above correction of your symbol-meanings you still find the formula to disagree with the scale marking, it it possible that you are using too approximate a value for f. Do you know the focal length to within, say, 5 per cent.? An error much greater than this would throw out your calculation of the scale division owing to the squaring of f in the formula. Your second question can only be answered by saying that the perspective of the projected picture is independent of the focal length of the taking lens, but is realised theoretically by a view point for the spectator at such a distance from the screen that the angle subtended by the screen at the eye is equal to the angle subtended by the image in the taking camera at the exit node of the lens. If your spectator's distance from the screen is fixed, then, of course, the focal length of the taking lens requires to be such as to fulfil the above condition of angle of view.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3243. Vol. LXIX. FRIDAY, JUNE 30, 1922. Price Fourpence.

Contents.

SUMMARY.

Mr. R. R. Rawkins, in a contributed article, is strong in his recommendation of collodion self-toning papers for professional portraits, and gives numerous hints on their manipulation. (P. 382.)

In a leading article we lay emphasis on some of the features of the Carbro method of making carbon prints. The difficulties of drying and keeping the tissue and of judging exposure are obviated and enlarged negatives dispensed with. (P. 382.)

We renew our cautions to assistants as regards the risks they run of losing specimens of their work by sending them to unknown persons. (P. 382.)

A photographer who had been in turn horse dealer, cab driver, editor, tea agent, dentist's manager, and debt collector, figured in the London Bankruptcy Court last week. (P. 393.)

In a paper from the Eastman Research Laboratory, Drs. Ludwik Silberstein and C. E. Kenneth Mees discuss the evidence supplied by the ultimate structure of the photographic emulsion film in favour of the modern quantum theory of the nature of light. (P. 384.)

The recent paper by Messrs. K. C. D. Hickman and D. A. Spencer before the Royal Photographic Society on the washing of negatives and prints, describes the authors' methods of testing the efficiency of various washing devices by observing the removal of a dye which they had found to be washed out in the same manner as hypo. (P. 387.)

In reference to the paragraph last week, Mr. W. B. Ferguson, K.C., mentions the reasons for which he discarded the use of oxalate in the copper toning bath when working out this process 22 years ago. (P. 394.)

A miniature reflex camera in L tube form has been invented as a focussing finder by an Austrian photographer. (P. 382.)

A correspondent cautions British manufacturers against irresponsible retailers in Japan who pose as wholesalers of standing. (P. 395.)

Mr. Ruddiman Johnston, of Tokyo, has patented a machine for the rotary printing of intaglio-engraved plates, in which the "doctor" is replaced by a rigid corrugated bar. (P. 390.)

Large claims are made in respect to a new developer patented by a German firm of chemical manufacturers. (P. 391.)

The thirty-second meeting of the Photographic Conventions opens on Monday next at Shrewsbury, under the presidency of Mr. C. Bellamy Clifton. (P. 381.)

The making of the ink and a laborious method of transfer without a press are two Continental Bromoil items. (P. 381.)

EX CATHEDRA.

The Convention. Next Monday Shrewsbury will welcome the Photographic Convention for the visit which will last throughout the week. It is the second time that the Shropshire county town has been the headquarters of the photographic gathering. The Convention met there in 1895, under the presidency of the late Mr. Alexander Haddon. This year the evening proceedings, in addition to the presidential address by Mr. Bellamy Clifton, will include lectures by Mr. Alfred Watkins, Mr. C. H. Bothamley and Mr. H. E. Forrest, the latter a lantern lecture on the old houses of Shrewsbury. Excursions will be made to Ludlow, Buildwas, Much Wenlock, Tronbridge, Bridgenorth and the far-famed Stokesay Castle. Old friendships are renewed and new ones made on these annual occasions, and while the Convention preserves the pleasant social character which has prevailed for so many years, it will continue to be a function the discontinuance of which would be regrettable. May its members next week enjoy the fine weather which, at the time of writing, they seem assured of having. In the pleasant Shropshire country and among the many beautiful examples of mediæval domestic architecture which it contains, they will find a multitude of subjects for their cameras.

* * *

Bromoil. Evidently no personal inconvenience or danger is allowed to deter the Bromoil enthusiast from preparing the means which are judged best for his process. Recently, Professor R. Namias, dissatisfied with the commercial inks, has been making his own, and after many experiments has decided that the best is prepared from boiled linseed oil and gum dammar. In a metal vessel, heated over an open fire, he dissolves gum dammar in twice its weight of the boiled oil, afterwards adding the requisite proportion of pigment, *e.g.*, lamp black, burnt sienna or prussian blue. The pigment is mixed with the varnish by putting a little of each on a sheet of glass and grinding with a spatula. If the ink is too hard it may be softened by incorporation of a similar varnish prepared with a smaller proportion of the dammar resin. In a German journal we note also the suggestion by Dr. Emil Mayer of an heroic method of making transfer Bromoils without a press. The principle is the production of great pressure over a minute area by means of a finely-pointed implement. The inked Bromoil is, in fact, laid face down on the transfer paper, smoothed thereon with a straight edge, and its back then "scrumbled" over with a lead pencil, the point of which presses the ink on to the transfer paper as it is firmly moved hither and thither. Even Mr. Bellamy Clifton must quail at the prospect and refuse to be enticed by such inducements as local variations in the transfer "touch." Moreover, Dr. Mayer has his misgivings, for he confesses that the process is "etwas langwierig." We should think so.

Printing Thin Negatives. It is not every photographer who is aware that a better print can usually be obtained from a thin negative by projection, as in ordinary enlarging, than by contact, but the experience of many skilled workers proves that such is the fact. The best results are usually obtained when the negative is illuminated by reflection from a white screen, as in the Boardman apparatus, but excellent results are obtainable with a condenser if one or more thicknesses of ground glass are interposed in the path of the rays. In some cases even a sheet of thin bank post paper may be used instead of glass. If this be done the cone of light from the centre is diffused, and reduction in the size of the diaphragm, which, of course, reduces the light still further, is permissible. When working on this system it is not practicable to use extremely slow papers, but with ordinary slow bromide the exposures will not be unduly prolonged, and in many cases the tone rendering is better than if a vigorous gaslight paper had been used. It will sometimes be found that if a negative be thin, but not flat, the latter papers give a somewhat harsh result, no matter how carefully the exposure is adjusted.

* * *

Assistants' Specimens. Several recent incidents prompt us once again to caution assistants applying for situations advertised in our columns, against sending specimens of their work to advertisers who use a Box No. There is no reason for sending specimens, for our publishers do not allow the request for them to appear in announcements appearing under a box number. Only by observing this rule can assistants assist our publishers in applying an effectual check to the abuse of our advertisement pages by unscrupulous or irresponsible people. Yet we are sorry to find that assistants continue to send what are often valuable specimens to people who are absolutely unknown to them. In such circumstances they have only themselves to blame if they are afterwards unable to obtain re-possession of the examples of their work. We had a case only a few days ago in which an assistant persisted in forwarding specimens to an advertiser unknown to him, after having been several times cautioned against so doing Our publishers' staff endeavour to the best of their ability to frustrate attempts to obtain photographs by underhand methods, and therefore assistants should at least follow the recommendations which will greatly remove causes of complaint respecting the loss of specimens.

* * *

A Focussing Finder. A new form of finder for attachment to a hand-camera has recently been described by an Austrian inventor, Herr Krone, who dwells upon its effectiveness in securing sharp focus in the use of cameras unprovided with a focussing screen. Essentially, there is nothing new in the invention, for the finder is actually a tiny reflex camera, the mirror in which is fixed whilst its lens is moved by the operation of the lens front of the camera to which it is fitted. The auxiliary miniature camera in its simplest form consists of a L-shaped tube having the mirror across the angle of the L, the focussing screen near the top of the upright limb and the lens in the end of the lower horizontal limb. In this pattern the lens requires to be of the same focal length as that of the camera proper; in more elaborate models it may be shorter, so as to permit of reduction of the size of the finder. The worst of such a fitment as this is that it must be attached when required for use, since it is obviously impossible to close a folding camera with it *in situ*. Experience is certainly against the commercial success of a loose accessory of this kind, however effective it may be for its purpose. Moreover, it is difficult to see how the finder can be made efficient, without greatly increasing its bulk, under the conditions in which it is most required, that is to say, when using a large-aperture lens of fair focal length. In these circumstances the focussing finder is almost bound to be pretty nearly as large and as expensive as the camera to which it is to be fitted. Makers of reflex cameras have no reason to fear that their instruments are threatened by devices of this kind.

CARBONS BY THE CARBRO PROCESS.

Theoretically, ordinary carbon printing is a very simple process, and it would at first sight seem almost impossible to make it simpler, but in practice there are little pitfalls which take years of practice to avoid, so that after half a century a really good carbon printer is still the rarest of photographic craftsmen. Those who have made a few dozen prints successfully may be inclined to dispute this statement, but at the end of six months' continuous working of the process they would probably acknowledge that there was still much to learn. This is not said with the idea of disparaging the process, which is well worth the labour of mastering, and which in the process of doing so will probably give very encouraging results. But we wish to point out that unless worked under favourable conditions the operations of sensitising and drying the tissue, the constant variation in sensitiveness which arises from keeping, and the correct estimation of exposure, all call for special care.

Most, if not all, the ills that carbon is heir to are obviated by adopting the Carbro process, which gives as the finished result a genuine carbon print, the ordinary tissue and transfer paper being used. Its chief main difference from carbon is that the image is formed by contact with a bromide print instead of by the direct action of light.

Full working details for the Carbro process are given in the current B.J. Almanac, or they may be obtained from the Autotype Company, who also publish an excellent handbook of the process, so that it is only necessary here to give a brief outline of the necessary manipulations. An ordinary bromide print is placed in cold water to soak. Meanwhile, a piece of carbon tissue of any desired colour is immersed in a solution containing bichromate, ferricyanide and bromide of potassium. In this it remains for three minutes, during which time the bromide print is taken from the water and laid upon a sheet of glass. At the end of the three minutes the tissue is withdrawn from its bath, allowed to drain for fifteen seconds, then immersed in a second solution containing acetic and hydrochloric acids and formaldehyde for an average time of twenty seconds, and squeegeed into contact with the print. It is placed in a fold of grease-proof paper and allowed to remain for fifteen minutes. At the end of this time the two are separated and the tissue squeegeed into contact with a piece of single transfer paper which has been soaked for at least five minutes. The mounted tissue is placed in blotting paper, under light pressure, for at least twenty minutes and developed in the usual way for carbon prints. The bromide print, which will have been wholly or partially bleached, is well washed, to free it from all yellowness and re-developed in amidol, when it is ready to produce another impression. As many as a dozen Carbros can be produced from one bromide, provided it is properly washed and fully re-developed after each bleaching.

The advantages of the process from the professional

worker's point of view may now be discussed, one of the most important being that the necessity of an enlarged negative which is needed for ordinary carbon enlargements is obviated; any good bromide enlargement serves as a basis. As no light is used to produce the carbon image, much time is saved, and there is no guesswork or actinometer needed to judge the exposure. Since also the tissue is used wet from the sensitising bath all drying troubles are eliminated and much valuable time saved. The print is developed upon its permanent support as in ordinary single transfer, but with the advantage of a non-reversed image, so that reversed negatives are not required.

A very interesting feature of the process is the large amount of control over the contrasts of the Carbro print, which can be obtained by varying the time of immersion in the second or acid solution; a brief immersion gives more and a longer one less contrast, thus ensuring the best possible results from any class of bromides. There are, of course, limits to this action, as nothing will put detail into lights where it does not exist, nor may a vigorous print be expected from a flat under-developed original. A somewhat astonishing trait is the fact that shadow detail which has been buried in the development of the bromide original is fully revealed in the Carbro print. Thus any detail which can be seen by holding the bromide print up to a strong light will be reproduced. This is an important point, as it would hardly be imagined that this would be the case. The reason for it is that it is the quantity of reduced silver in the print which forms the carbon image, irrespective of its visual appearance. In extreme cases it is possible to get a good result from a bromide which is nearly black all over by regulating the time of immersion in the acid bath.

Those who essayed the process when it was first introduced by Mr. H. F. Farmer in 1919 and were not satisfied with the results will probably find their difficulties removed by trying the modified procedure of Mr. F. Garon, which has now become the standard adopted by the Autotype Company. If for any purpose a reversed print or a non-reversed one from a reversed negative is wanted the tissue may be squeegeed upon flexible support or waxed opal and treated as for ordinary double transfer. For Carbros on ivory the bromide may be made by reduction in the lantern or camera, the glass side of the negative being turned to the lens. This gives a reversed bromide, which by double transfer is correct upon the final support.

SELF-TONING COLLODION PAPER FOR PORTRAITS.

Is the print-out paper for portraits likely to be popular again?

There are many indications that point to a revival of daylight printing processes, especially collodion. It appears, however, that P.O.P., which requires a separate toning bath, is on its last legs. At the Photographic Fair the collodion self-toning papers were much in evidence, and there is now a healthy competition amongst British manufacturers which will do a great deal in popularising this beautiful process.

I have found the average professional photographer inclined to be a trifle contemptuous in speaking of self-toning papers. One photographer said to me: "It is an amateur's paper, and no earthly good to the professional who wants his results to *stand*." It seems pretty clear that there is a general feeling that these papers do not give permanent prints, but I am convinced that this is an entirely erroneous idea. It is all a matter of correct treatment in fixing and washing. I have seen collodion self-toning prints that were made thirteen years ago, and I have many of my own (on Paget and Seltona) over twelve years old, which are quite as perfect now as when first produced.

It must therefore be a matter of correct technique, and the object of this article is to endeavour to point out possible errors in manipulation.

It may be argued that the demand for speed, which is so insistent nowadays, absolutely precludes the use of a paper that demands a printing-frame and visual examination. But, does it? It is admitted that the process may not suit the cheap post-card man (although I know one man who is doing a good business by it), but with girl labour under supervision it is surprising how many prints can be obtained in a day without much waste. Print-out photographs are invariably approved by the general public, and every practical photographer will agree that there is "something" about a print-out picture that makes it different from a development picture.

The richness of tone, complete absence of hardness or excessive contrast, and the rendering of a long scale of gradation are the principal attributes of the self-toning (collodion) papers. It must be borne in mind that the great general public are becoming more discriminating, and by practising photography as a hobby their knowledge of processes is increased. Nowadays a very large section of the public regards the "soot-and-whitewash" postcard as anathema; and rightly so. Photographers know that these "hard" things do not represent the possibilities of the bromide process, but they are foisted upon certain sections of the public as "good" pictures.

Here, then, is a great opportunity for the portraitist to introduce a new "line," which will, I feel sure, be a financial success, provided the technical management is on the right lines. Look at the surfaces and colours that are now obtainable! The cream matt and rough surface give pictures of singular beauty and distinction, and it is practically impossible to get double tones.

As regards the technical side of the question one is quite safe in following the makers' directions, but there is considerable difference of opinion as to whether the prints should be washed before fixing. With one paper my practice was to place the prints direct into the alkaline fixing bath, but I must confess to a liking for a paper which has to be washed first.

In toning a large batch there appears to be less chance of chemical complications when the prints have had a preliminary wash to remove the "free" silver. The glossy papers usually require to be placed first in salt solution, so as to obtain the purple colour which is suitable for this surface.

The class of negative best suited to collodion self-toning paper is one on the thin side, but not weak. The glossy paper gives greater contrast than any other surface. A very hard negative with clear glass shadows is apt to give bronzed darks in the print, unless a little colour or matt varnish is put on the negative. A great deal can be done in the way of sunning down excessive contrast, and in the practice of centralising the lighting a local exposure of the printed picture to daylight will do all that is required.

The process is of no use to the slap-dash worker who uses one dish for everything. To be entirely successful it is necessary to be very methodical and clean. The dishes used for the preliminary washing must not be used for the hypo solu-

tion, or for the washing after fixing. Quick changes from one dish to another is a good way of removing the "free" silver, and fixing should not be done until the washing water remains quite clear.

The washing and fixing should be done in large shallow trays, and the prints handled face down, so as to minimise curling. With this process there should be no leaving the prints to soak or wash. They must be kept on the move all the time, and not left until they are hanging up to dry.

The hypo solution should be freshly made, of a strength 3 ozs. to the pint of water, and if there is the slightest suspicion of the bath being acid a few drops of ammonia or a pinch of bicarbonate of soda must be added. As regards the number of prints that a given amount of hypo will fix perfectly, a good guide is to use just as much solution as will allow of the prints being handled comfortably in it. The hypo solution must not have been used before for any other purpose, and a full ten minutes must be allowed for fixation.

The washing to remove the hypo must be very thorough; at least eight complete changes should be given, occupying a total time of one hour. The prints can then be placed on a slab of clean, thick glass, one on top of the other, and firmly squeegeed to remove some of the water. The face of each print should be blotted with a chemically-pure blotting paper, and hung up to dry. I find that a very convenient method of drying is to use American wooden clips threaded through galvanised wire, and to hang the prints in pairs back to back. This prevents a great deal of curl. When dry the prints should be straightened in the usual way, but if heat is used to dry them (which can be done quite safely) they should be straightened before they are bone dry.

There is one other item which is an essential to permanence, and that is dry-mounting by the hot press. The dry-mounting tissue interposes a thin layer of waterproof material between the mount and the picture, thus preventing any possible emanations from the mount affecting the picture.

The glossy surface can be glazed on glass, but I find a much better method of obtaining a high gloss is by the use of encaustic cereate, or Lustralene. A little of this rubbed on with a piece of flannelette and polished with another piece of soft material will give a good gloss with the added advantage of removing all traces of bronzing in the shadows. This paste can be used on the other surfaces if desired, and will make the shadows appear rich and luminous. Further, this thin coating of paste must afford considerable protection from damp, the products of combustion, or impure atmosphere, thereby ensuring permanence. Spotting or working up should be done before treating with the paste, and will not rub off if handled gently.

In conclusion, there is no sepia or brown tone obtainable on any development paper that will surpass the rich colours so easily obtained by the self-toning collodion process.

R. R. Rawkins.

PHOTOGRAPHIC EXPOSURE AND THE STRUCTURE OF LIGHT.

(Communication No. 144 from the Research Laboratory of the Eastman Kodak Company.)

The method by which a photographic emulsion adds up light during a long exposure has always been a problem for which no adequate explanation was forthcoming. The sensitive material in the emulsion consists of microscopic crystalline grains in the form of flat triangular or hexagonal plates of a variety of sizes, ranging from spots which are only visible as specks under the highest power of the microscope to crystals which are easily visible and show clearly defined form. If these grains are exposed to light and receive a sufficient exposure, they become developable, and it is generally considered that once a nucleus for development has been formed the entire grain will be reduced to metallic silver if developed for a sufficiently long time.

Keeping this in mind, consider an emulsion exposed in a telescope to the image of a star, for instance. At the end of a very short exposure apparently no grains at all might be developable, and no image of the star would be obtained. Nevertheless, some change has occurred to the grains if we accept the idea that they have been continuously exposed to light, because, if we go on exposing, presently some of the grains will be developable, and after hours of exposure enough grains will be developable to make a good image of the star.

If we think that the light is falling continuously on the grains, then they must have some mechanism for storing extremely small amounts of energy below that necessary to make them developable until they have enough for developability. It is not impossible that some chemical mechanism could be conceived, but the problem presents some difficulty, especially as the effect of an exposure is not greatly lost on interruption. On the assumption that the grains are continuously acquiring exposure, we must assume that they will not lose, even after weeks, their record of an exposure insufficient to make them developable and will re-start exposure practically where they left off.

Another difficulty which arises when we study the exposure of the individual grains is that they appear to differ in sensitiveness; the bigger grains behave as if they were very much more sensitive than the smaller, and there are often differences in sensitiveness among grains of the same size, because if we sort out a number of grains, all of the same size and shape, under the microscope, they will not all become exposed at the same time; some of them will become developable before others, and if we imagine that they have all been exposed to a uniform continuous flood of light we must admit that these grains differ in sensitiveness among themselves. This has recently been dealt with by Svedberg in his paper on the relation between sensitiveness and size of grain in photographic emulsions.[1] Svedberg finds that the centres of reduction in exposed grains are distributed according to the laws of chance. In the discussion of this paper Dr. Lowry suggested that it might be that these developable centres provided a concrete record of the bombardment of the silver bromide targets by quanta of light.

The situation is similar to that which a row of soldiers in the trenches would present to a spectator who had no idea of the existence of projectiles on the battlefield. He would observe men falling, and would conclude that there was a continuous wave of death coming over from the enemy's trenches, and that the soldiers differed in their "sensitiveness" to death, so that one man was killed while another remained apparently unhurt, though if they remained exposed for a sufficiently long time ultimately all would be destroyed.

If we had no prior knowledge of the wave theory of light, the simplest explanation of the apparent difference in sensitiveness of different grains would be that, instead of a continuous flow of light in the form of waves on to the sensitive film, the light was falling upon it as a rain of projectiles; these projectiles would make developable any grains that they hit, the grains which were missed not being affected at all. If the grains continued to be exposed to the radiation they would be hit later and thus be made developable in their turn.

The radiation of light in the form of projectiles is a very old idea in physics. Indeed, the theory which Newton held as to the nature of light was that it consisted of a stream of very minute corpuscles moving with great velocity and bombarding the material objects which they met. This theory was displaced by the wave theory

1. "Phot. Journ.," April, 1922, p. 186.

owing primarily to its inability to explain the phenomenon of interference, but many recent discoveries in physics have been found difficult to explain by the use of the classical wave theory, and it seems not unlikely that it may be necessary to turn to a theory having some analogy to the corpuscular theory of Newton.

The origin of light-emission is now ascribed, not to the molecules of matter or even to the atoms as a whole, but to the "electrons" or smallest particles of negative electricity in their interaction with the nucleus of the atom. There are good reasons for assuming the atoms of the chemical elements to consist of a "nucleus" carrying a positive charge of electricity surrounded by one or more electrons carrying negative charges, the whole atom being electrically neutral. It is thought that these electrons revolve about the positive nucleus, more massive than the electrons, and that on their number and the corresponding charge on the positive nucleus depends the nature of the atom. Thus hydrogen, the lightest of all elements, has one electron revolving in a circular or elliptic orbit about its nucleus. Helium, the next element, has two electrons; lithium, three; and so on.

The electrons are supposed to revolve around their nuclei without radiating, but when an electron suffers some violent shock it jumps from one of these so-called "stationary" orbits to another and gives up energy, which is radiated out in the form of waves having the very remarkable property that the frequency of the vibration emitted is exactly proportional to the energy which is released. The wave-length, of course, depends upon the frequency; the more waves there are emitted in a given time the shorter their length must be, since the velocity of light is constant; so that when an electron loses a very little energy it gives out long waves, and when it loses a great deal of energy it gives out very short waves.

In an X-ray tube the discharge of electricity is in the form of a stream of corpuscles travelling with a velocity which is very high and which depends upon the voltage of the electric current applied to the tube. When these corpuscles strike the target their energy is radiated in the form of X-rays, and we know now that these X-rays partake very closely of the nature of light, except that the length of the waves is about one-thousandth of those of light, or, what is the same thing, their frequency is a thousand times as great. It is to this that they owe their great penetrating power.

On the classical wave theory of light, then, we should imagine that an X-ray tube, having its target bombarded by the stream of corpuscles produced by the current, would emit waves of X-rays spreading into space just as waves of light are imagined to spread from a source; but now comes a great difficulty: When these X-rays, travelling out, pass through a gas and are absorbed, they cause the molecules of the gas to emit electrons, and these electrons are emitted with almost exactly the same velocity as the electrons in the tube which produced the X-rays themselves.

The possibility of applying the quantum theory of radiation to photographic exposure has been hinted at by a number of writers before the paper already referred to by Svedberg. Thus, it is mentioned by F. E. Ross[2], who notes that such a theory would lead to a mass-law formula for photographic exposures, but does not enter into the details of the probability problem, and does not develop the theory. R. E. Slade and G. I. Higson[3] consider the possibility of a light-quantum theory, and write a formula (of the Elder type) for the exposure of a photographic material with the qualitative comment that on such a theory the coefficient of the formula would vary with the size of grain, but since such a theory will not lead directly to an explanation of what is known as the failure of the reciprocity law they abandon it as "impossible."

In the discussion of Svedberg's paper, Mr. Storr and Mr. Hickman pointed out that the results obtained could be explained either by assuming a discrete structure in the light or by assuming some specific distribution of sensitiveness in the grains themselves prior to and independently of the light-action.[4] Such a theory will certainly present considerable difficulties before it can be reconciled with the experimental facts to be described presently, but in the research laboratory of the Eastman Kodak Company work is in progress by means of which it is hoped to decide definitely for or against the latter theory.

A consideration of the subject led L. Silberstein to develop a mathematical theory based on Einstein's assumption of light-quanta; i.e., of a discrete structure of radiation which, together with several experimental tests, was given by him in a paper read December 28, 1921, at the Toronto meeting of the American Physical Society. The experimental work by A. P. H. Trivelli and I. Righter undertaken in the research laboratory of the Eastman Kodak Co., with the purpose of testing this theory, has provided ample evidence as to the relation between the size of single grains and of clumps of grains and the percentage of them which become developable on exposure. Their results agree very well with the deductions from Silberstein's theory. This work of Silberstein and that of Trivelli and Righter corroborating experimentally his theoretical formula are now being published in the "Philosophical Magazine," to which readers are referred for all details and the mathematical treatment of the problem, while in the present article but a bare outline of the subject can be given.

According to Einstein's hypothesis of 1905, light may be considered to be radiated and propagated in quanta, which consist of limited trains of monochromatic light-waves, each train containing a quantum of energy, the value of which is the product of Plancke's constant h and the *frequency*. Somewhat more generally, it may be assumed, as has been done by E. Marx and J. J. Thomson, in distinction from Einstein, that not the whole radiation but only part of it is split into these quanta, the light-energy being densely concentrated in minute specks scattered haphazard over an otherwise continuous distribution of radiant energy. Further, according to Einstein's photo-electric law, verified most accurately by numerous experiments, the liberation of a photo-electron from an atom requires just one quantum of light-energy, which reappears as the kinetic energy of the ejected electron, except for the fraction used up in freeing the electron.

Now, Jolly has already suggested that the mechanism by which a silver halide grain is affected by light is such a photo-electric liberation of an electron, and the combination of the two theories leads us at once to a view of light-quanta travelling independently of each other in the form of limited trains of waves of a minute cross-section and striking the crystal grains in such a way that they are absorbed and, upon absorption, liberate an electron.[5] For these light-quanta Silberstein has suggested the term "darts of light." He has calculated the chance that a grain of any size would be hit by such a projectile and would thus become developable. Naturally, the bigger the grains, the more likely are they to be hit, so that a relation can be found between the size and the number of grains which will become developable after a given exposure.

If k be the number of grains which have been affected by an exposure to n light-quanta, the grains having a projective area a; and, if there are N grains to be affected, the rigorous and rather complicated probability formula gives for large values of N and any n, with more than sufficient approximation,

$$k = N(1 - e^{-\frac{an}{N}}) \qquad (1)$$

This follows under the assumption that the cross-section of the light-darts is negligible as compared with a. If that cross-section, say δ on an average, is taken into account, and it is required that the grains to be affected should be fully hit by the light-darts,[6] the somewhat broader formula,

$$k = N(1 - e^{-\frac{an'}{N}}),\ a' = n\left(1 - \sqrt{\frac{\delta}{a}}\right)^2 \qquad (2)$$

is obtained.

When the equation (1) was compared with experimental results it was found that the bigger grains become affected even more quickly as compared with the smaller grains than they should have done according to this formula. A possible explanation of this is that we cannot assume that the cross-sections of the light-darts are of negligible area compared with the grain, and it may be that they have appreciable diameters, varying over a wide range, but of an average size comparable with that of the smaller grain. If such be the case and the broader formula (2) is applied, then, from the rate at which the grains of different sizes become developable, the average cross-section area of the light-darts, or whatever the parameter δ stands for, can be calculated.

Trivelli and Righter, studying the sensitiveness of clumps of grains formed by the attachment of two or more small grains together, found experimentally that if one of these grains is affected

3. "Proc. Roy. Soc.," Volume 98, 1920, pp. 164-170.
4. This was also suggested and discussed by S. E. Sheppard in a recent paper on "Size Frequency Distribution of Particles of Silver Halide in Photographic Emulsions and its Relation to Sensitometric Characteristics." See also paper on "Action of Soluble Iodides and Cyanides on Emulsions," "Phot. Journ.," Feb., 1922.

5. It is by no means certain that the mere liberation of an electron is a sufficient cause for developability.
6. Always of sufficiently high frequency, i.e., exceeding the critical frequency below which no photo-electron is liberated.

by light, the whole clump becomes developable.[7] Thus, a clump of four small grains will act just as if it were one large grain or target of just the same total area, due allowance being made for the overlapping of the grains. It is consequently possible to calculate the rate at which clumps containing different numbers of grains will be affected by the light, and when the experiments were made and the numbers of affected clumps containing two, three, four, and more grains were counted, it was found that these numbers agreed very closely with those which were calculated by means of the aforesaid formula (2).

In Trivelli's and Righter's work a simple bromide emulsion of minimum speed and contrast, and having grains of an average size (area) of about 0·9 square micron, was used for the experiments. The experiments were performed as follows:—A plate coated with the original emulsion was soaked in distilled water for half-an-hour and then covered with a warm solution of gelatine, alcohol, and water, in which it was maintained at a temperature not over 40 deg. C. for 20 minutes. By this means the emulsion was removed from the plate, and the solution was then diluted, so that upon coating and drying a single layer of grains was obtained on the glass plate. After exposure in a sensitometer the plates were developed to γ_∞, washed, and the developed silver removed with a dilute solution of chromic and sulphuric acids. The strips thus treated contained the undeveloped grains and clumps, and the numbers $(N-k)$ of the grains and clumps of different sizes (a) thus left unaffected were counted. Subtracting these numbers from the numbers N of grains and clumps originally present, the numbers k of grains and clumps affected were obtained. So far only the first three "steps" of an H. & D. sensitometric strip have been counted, a week or two being required for the area measurements and counts relating to each step. Twenty of these on each of three strips are employed to determine the developed grains, while to determine the number of grains and clumps in the original one-grain-layer plate before exposure and development ten of these on each of four strips were used. The results in both cases are reduced to the number of grains or clumps per square centimetre of a one-grain-layer plate. The following table shows the results obtained for the first step, as compared with the values calculated according to Silberstein's formula (2) with $n=0.572$ per square micron, and the "average" area of the cross-section in a light-dart $\delta=0.097$ of a square micron:—

Clumps of	a in μ^2	$\frac{100k}{N}$ Observed	$\frac{100k}{N}$ Calculated
1 grain	0.75	16.5	15.2
2 grains	1.93	44.9	48.4
3 ,,	3.03	76.6	68.9
4 ,,	4.88	87.1	87.3
5 ,,	6.20	96.0	93.3
6 ,,	7.40	98.2	96.4
7 ,,	8.6	100.0	98.0
8 ,,	9.8	100.0	99.6
9 ,,	11.0	100.0	99.8
10-31 ,,	12-23	100.0	100.0
32 ,,	> 24	100.0	100.0
33 ,,	> 25	100.0	100.0

The most reliable a values are those for the clumps of one and of two grains, being averages of the largest numbers of individual clumps; the following a values are gradually less reliable. The calculated values in the above table were obtained from the equation (2) given before, containing a term which allows for a finite cross-section and hence a finite diameter of the light-dart, the average diameter according to this calculation being approximately one-third of a micron, and the number of light-darts falling on the plate for this exposure being about one for every two square microns.

The above value of n would give approximately 57,000,000 light-darts per square centimetre; a judgment whether this allots to each dart just one quantam of energy in Plancke's sense of the word must be suspended until absolute energy measurements of the exposures are available. Since each light-projectile is presumably of the order of some hundred of thousands wave-lengths in length, the name "light-dart" seems not inappropriate in view of the assumed small cross-section. On Einstein's own theory there is nothing on which to base the estimate of the dimensions of the light-quantum,[8] but on Thomson or Marx's less radical theory of "concentration places" within a continuous distribution of light-energy the characterisation of a light-dart as having a section of $0.097\mu^2$ would mean a length (at wave-length $470\mu\mu$) of abont 6,000,000 wave-lengths. When the measurement of the second "step" of the sensitometric exposure was completed, the same value of the cross-section of the light-dart was taken, but with the exposure value of half that of the former set, i.e., $\delta = 0.097$ and $n = 0.286$. The experimental results (apart from the second doubtful item) agree admirably with the calculated ones, as is shown by the following table, thus forming a striking confirmation of the theory:—

a in μ^2	$\frac{100k}{N}$ Observed	$\frac{100k}{N}$ Calculated
1.93	21	28.2
3.03	57	44.2
4.88	63.8	64.3
6.2	74.5	74.3
7.4	87.5	81.0
11.0	97	92.4
12.0	97	94.2
12-23	100	96-100
24	100	100
25	100	100

Similarly, for the third "step" the same formula, but with the exposure value of one-half of the second step ($n = 0.143$), gave the percentage numbers of clumps affected (for clumps of 2 up to 10 grains), 15, 25, 41, 49, 56, 63, 68, 74, 76, agreeing well enough with the observed values, which were 13, 38, 42, 53, 66, 82, 86, 78, 89 respectively. An account of further measurements in this and other sets of experiments now in progress will be published as these are completed.

Naturally, many questions relating to this theory come to our mind: Are we to suppose all the light-darts of the same average diameter or does the average diameter depend upon the frequency? How are we going to explain the difficulties of interference and diffraction of light? We are far from being able to answer these questions. Some of them can perhaps be dealt with experimentally, some mathematically, some will have to wait for new facts and new methods of attack. As soon as the photographic measurements can be made it will be possible to determine whether the darts of X-rays, for instance, behave similarly (and as if they had the same diameter) to darts of visible light. This may settle the question as to whether the light darts vary in diameter with the frequency. The problems presented by interference and diffraction can perhaps be dealt with statistically. All that we can say at present is that it is not impossible that these phenomena may be explained on the hypothesis that light consists of separate trains containing many waves of light. The mechanism by which an electron emits a light-dart, which, moreover, satisfies the relation between its energy and the frequency of the radiation emitted, is, and will perhaps for a long time remain, entirely unknown. Since the amount of energy in a light-dart is very small, light of ordinary intensities contains enormous quantities of them, and it is only in exceptionally favourable cases that any distinction could be detected in the effects produced upon matter between a continuous radiation of energy as demanded by the older theory and a shower of projectiles or light-darts. A rain of arrows, for instance, if sufficiently closely packed would have just the same effect upon a material as hitting it with something solid; it would make practically no difference that the arrows are separated by small intervals in space and time, and in the same way we should expect that the continuous wave theory would appear to hold except where we might have methods of exposing an assemblage of sufficiently small individual particles to a shower of light-darts *not outnumbering the particles very much* and observing what happened to them. Such conditions are precisely afforded by properly prepared photographic emulsions, which thus seem admirably adapted to reveal the discrete structure of light.

7. Although Svedberg obtained in his recent investigation ("Phot. Journ.," April, 1922, p. 183) what would seem an independence of the grains forming a "clump," yet Trivelli and Righter are confident in their result which they have repeatedly verified. The apparent discrepancy is probably reducible to the circumstance that Svedberg worked with small spherical grains which have not been in such an intimate contact with each other as Trivelli and Righter's plate-shaped grains, partly overlapping and piled upon each other.

8. In his original paper of 1905 ("Ann. der Physik," Vol. 17, p. 132) Einstein speaks of each quantam of light-energy as concentrated in a "space-point," but this is scarcely more than a brief expression, and is certainly unessential for Einstein's reasoning.

When a beam of X-rays falls upon an atom and liberates an electron we have the means of detecting the action of a single quantum, which is necessary in order to detect the difference between a continuous radiation and a shower of light-darts, and the observation that the electron thrown out of an atom by impact of X-rays travels with the same speed as the original electron by which the rays were generated is exactly what we should expect to be true on the light-dart theory. This theory, of course, is, as yet, in its infancy, and there are many difficulties which it will have to meet, but if we had not been, for several generations, under the influence of the continuous wave theory of light and were considering only the facts known to us, it is quite possible that the difficulties presented to the ordinary wave theory by the photo-electric effect, the absorption of X-rays, and the behaviour of the photographic plate would appear not less formidable than those which the problems of interference and diffraction actually present to the light-dart theory. Fortunately, the theory leads to many experiments, and one may perhaps be able to come to definite conclusions as to its value as soon as the experiments which are indicated can be carried out.

LUDWIK SILBERSTEIN.
C. E. KENNETH MEES.

THE WASHING OF NEGATIVES AND PRINTS.

[A paper recently read before the Royal Photographic Society by Messrs. K. C. D. Hickman, B.Sc., and D. A. Spencer, A.R.C.Sc., entitled, "A Constructive Criticism of Washing Devices and Optical Method of Testing," has been printed in the Society's "Journal" as the first part of a comprehensive communication on this subject. As will be seen, as soon as one has crossed the formidable barrier of the chemical equations and mathematical formulæ, one encounters a great many experimental data bearing directly upon the practical methods of washing negatives and also prints. With much ingenuity the authors illustrate side by side their experiments and the results obtained as regards uniformity and completeness of washing, and they describe their inventions for the washing of plates, among them one which has already been placed upon the market in the shape of the Hickman "Circulator." The paper certainly represents the most scientific experiments which have been made on the removal of hypo from gelatine films by washing, and are deserving of a close study on account of the great amount of practical information which it contains.]

THE theoretical side of washing by successive changes of water has been dealt with recently by Elsden[1] and Warwick,[2] who have shown that complete removal of hypo from a photographic plate can be obtained in a short time with a small expenditure of water.

An editorial note[3] on Warwick's paper remarks:—". . . it would seem that Mr. Warwick adopts a higher standard of freedom from hypo than that chosen by Mr. Elsden. Such standard, in the absence of experimental evidence, must be a matter of choice."

This experimental evidence is difficult to obtain, but the necessary degree of freedom can be deduced on theoretical grounds. Lumière[4] states that the fading of silver prints is probably due to conversion of the silver to sulphide, and brown Ag_2S turning to a light yellow variety in the course of years.

We agree that the conversion to sulphide probably occurs; but can find no evidence to support the theory of a more stable allotropic form. It would appear more likely that the silver is converted through sulphide to sulphate, which, in the presence of sulphuric acid or other hygroscopic material, is able to diffuse laterally, or into the support.

Assuming a photograph to be perfectly fixed, and the absence of silver thiosulphate in the film, the process of fading might be explained as follows, the upper arrows showing the direction in which the equilibrium sets.

(1) $2Ag + Na_2S_2O_3 \rightleftharpoons Ag_2S + Na_2SO_3$.
(2) $2Na_2SO_3 + O_2 \rightleftharpoons Na_2SO_4$.
(3) $Na_2SO_4 + Ag_2S \rightleftharpoons Na_2S + Ag_2SO_4$.
(4) $Na_2S + CO_2 + H_2O \rightleftharpoons Na_2CO_3 + H_2S$.
(5) $Na_2S_2O_3 + 2O_2 + H_2O \rightarrow Na_2SO_4 + H_2SO_4$.

Equations (1), (2) and (5) show that there is a tendency for the formation of silver sulphide and an excess of sodium sulphate. All reactions being strictly reversible, minute quantities of sodium sulphide and silver sulphate will be formed as in (3), and the sodium sulphide will be decomposed by atmospheric gases (4). As hydrogen sulphide precipitates silver sulphide quantitatively from sulphate solutions, it will require a large excess of sulphate, and complete removal of H_2S, to reverse the reaction. These conditions exist, however, in a photographic film containing sodium sulphate and sulphuric acid, from which the gas is freely permitted to escape.

It will be assumed, then, that thiosulphate is comparatively harmless when it is present in proportions indicated by equation (1), a change to sulphide only slightly altering the colour. This quantity must be calculated for the lowest density which it is desired to preserve. Taking this as $d=0.1$, and the photometric constant as 0·0103 gramme Ag per 100 cms.[5] for plates, then the greatest permissible quantity H of hypo per square decimetre is given by $H = 0.0103 \times 0.1 \times 1.5 = 0.0016$ gramme, where $Na_2S_2O_3 : Ag :: 1.5 : 1$. This is a maximum quantity, and a safety factor of 10 is suggested, bringing the limit to 0.00016 gramme, or 0.0013 gramme per quarter-plate. In the following experiments, therefore, a plate is considered completely washed when it contains less than this amount.

Soluble salts in general are said[5] to diffuse exponentially with time from gelatine films into water. This was verified for hypo diffusing from gelatine-coated negative plates into water, two series of experiments being performed. (1) Freshly fixed plates were soaked in successive changes of water, time being allowed for the concentrations in film and liquid to reach equilibrium. (2) Plates were washed with large quantities of water, projected at their surfaces with as great a velocity as the films would stand. The results in the first case were contradictory amongst themselves, the discrepancies being attributed to a faulty experimental method. It is hoped to deal with the matter in a further paper. Experiments (2) indicated that under the second conditions the exponential law held good, the quantity of hypo diffusing away at any time being proportional to the amount left in the film at that moment. The quantity of hypo M, washed out of the film in a period t minutes from the start is given by

$$\frac{dM}{dt} = K(A - M),$$

where A = quantity of hypo originally present, and K is the elimination constant for the film.

$$\text{Then } \int \frac{dM}{A - M} = \int K dT$$

$$\therefore \log \frac{A}{A - M} = Kt,$$

$$\text{whence } K = \frac{1}{t} \log \frac{A}{A - M},$$

which may be written:

$$K = \frac{1}{t} \log \left(\frac{\text{initial concentration in film}}{\text{concentration at time } t} \right).$$

The value K is independent of the initial concentration and may be obtained from

$$K = \frac{1}{t_2 - t_1} \log \left(\frac{\text{concentration at time } t_1}{\text{concentration at time } t_2} \right).$$

Whence, the time required to reach any limiting concentration C_L is given by:—

$$t_L = \frac{1}{K} \log \frac{C_n}{C_L} + t_n,$$

where t_n is any given time.

1. "B.J.," 1917, 120.
2. "B.J.," 1917, 261.
3. *loc. cit.*
4. "B.J.," 1902, 226.
5. Sheppard and Mees' "Theory of Photographic Processes."

Clearly, these equations cannot be used to predict the time of washing for any case in which the exponential law does not hold good. In most methods of washing met with in practice, a state of affairs somewhere between the two cases is found. This has been allowed for by previous workers by using the exponential formula and varying the factor K to suit the altered conditions.

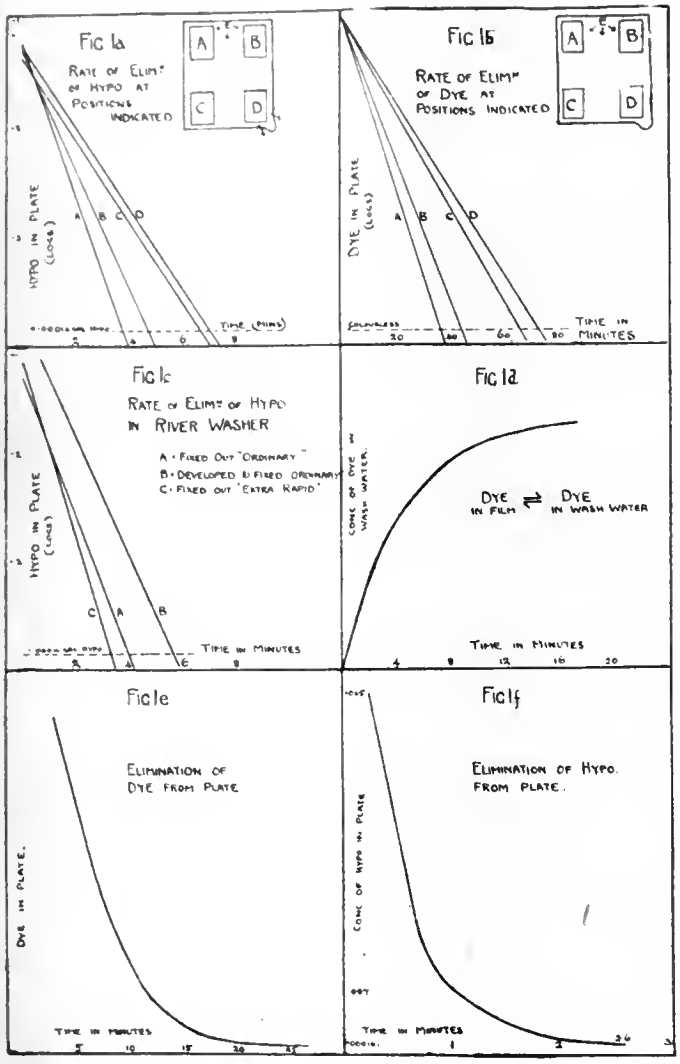

Plate 1.

This is, at best, a makeshift. The particular value to an investigator, of a formula for deducing the time for complete washing lies in the unreliability of volumetric methods of estimating hypo. In titrating with iodine, the correction to be applied for the starch used as indicator is often greater than the value of the thiosulphate found when the latter is only present in minute amounts. It is therefore difficult to tell if a plate is completely washed by titrating the residual salt with iodine and starch. The method becomes accurate, only when the hypo content is great, *i.e.* in the early stages of washing. Here the time error is large owing to the difficulty of placing and removing the plate sufficiently quickly from the wash water, of blotting evenly, and preventing diffusion to adherent solution while doing so.

The validity of our experimental results depended, other factors being constant, on the similarity of gelatine thickness, hardness, etc., and the maintenance of a similar working temperature for each plate. Adequate precautions were taken to ensure regularity of conditions and, where possible, each series of experiments was conducted on large plates cut into strips. In each case a portion of the plate was dyed in Tartrazine,[6] and the diffusion time for the dye under standard washing conditions noted. This enabled a small correction factor to be applied. In experiments (1) above, the wash waters were united and titrated with N/100 iodine. Plates in experiments (2) were washed in four successive changes of water, for five minutes each, and the washings titrated as before. The washing times in the latter case are plotted against the logarithms of the hypo concentrations in Fig. 1*f*, Plate 1. The time for washing to the limiting concentration is thus only 2.6 minutes under these abnormal conditions. The plates adopted throughout the experiments were "Wellington" Ordinary. They were soaked in water for 10 minutes, then for two changes of 5 minutes each in 20 per cent. hypo, after which they were used.

In order to test whether the omission of development prejudiced the results, four plates were fogged, developed in metol-hydroquinone to a uniform density of about 0.5, washed, and treated as before. It was found that considerably more hypo was absorbed, but that it washed out at approximately the same rate as that from an undeveloped plate. This, together with a comparative curve for ordinary and extra speedy press plates, is shown in Fig. 1*c*, Plate 1. The curves were obtained by means of the river washing device.[7]

Until a method of measuring very small quantities of hypo becomes available, it is necessary to attack the problem in a different manner. An ideal weapon would be provided by a highly-coloured salt having the molecular weight and other physical properties of hypo. This could be used to bathe plates, and the manner of washing noted visually. The subject could then be attacked qualitatively as well as quantitatively in a manner which appears previously to have been overlooked. Qualitative examination is important because a plate may contain less than the theoretically objectionable quantity of hypo calculated for its entire surface, but this quantity may be, and often is, located in a small area where it can do great harm. Qualitative examination should reveal local concentrations, and thus indicate the forms of apparatus which give faulty washing.

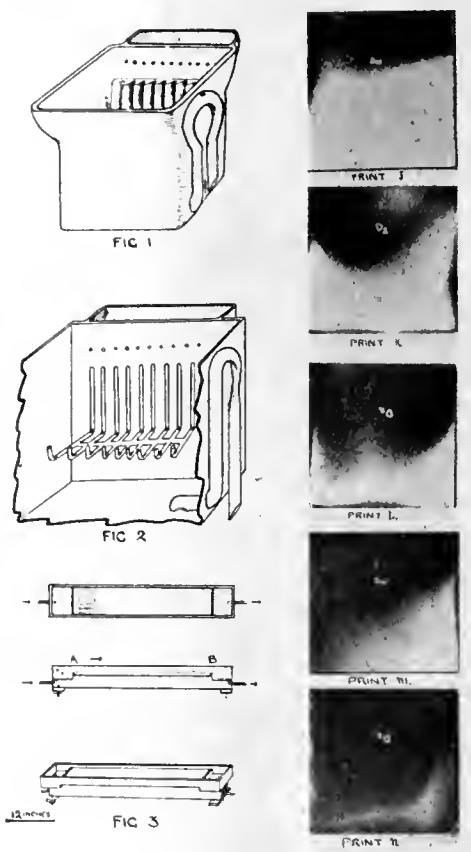

Plate 2.

Most highly-coloured inorganic salts modify gelatine and are unsuitable for the purpose. A number of dyestuffs were examined, and a few selected, which diffused from gelatine without leaving

6. See later.

7. See later.

a stain. Of these, Tartrazine[2] was shown to diffuse exponentially with time, plates dyed for 3 minutes in 2 per cent. solution clearing in about 30 minutes in running water. The curves for the rate of elimination and for the attainment of equilibrium with wash water are given in Figs. 1*d* and 1*e*, Plate 1. The times of diffusion and attainment of equilibrium are much greater than for hypo, alteration of the conditions of washing affecting the two differently, though in the same direction. Increase in the quantity of wash water causes both dye and hypo to eliminate more quickly. The dyed plate, taking longer to reach equilibrium, will be less affected by an irregular water supply, any selective washing indicating an even greater lack of uniformity had hypo been used. It is thus quite suitable as a qualitative substitute for the latter.

Plates were fixed, washed, and dyed in 2 per cent. Tartrazine for 3 minutes and dried. To test the efficiency of a washing device, one or more plates were placed in it, and the time noted for complete removal of colour. If irregular washing occurred, it was recorded by removing the plate, blotting the surface, and making a print from the glass side on to "vigorous" gaslight paper, using a metal filament lamp, screened by a solution of ammoniacal copper sulphate to give maximum contrast with the yellow dye.

As a preliminary, the water-changing properties of the various washing devices were examined. Taking as standard an imaginary washer which received and discharged water at a uniform rate, the incoming stream mixing perfectly with the contents of the vessel before discharging, it will be seen that washers may be divided into those which are more, and those which are less efficient than this theoretical example. Thus, water falling into the deep end of a tilted dish will overflow before it has diluted the contents, and the replacement will be less efficient than the example cited. On the other hand, with the intermittent siphon tank (Fig. 2, Plate 2), where the incoming water displaces the old solution with little mixing, the dilution is very rapid. The rate of dilution (obtained by estimating tintometrically the decrease in strength of a dye solution placed in the washer) was found quantitatively for all the apparati which were used. The results are given in Plate 3.

It would be expected that if the rate of plate washing were a function of the efficiency with which stale solutions were removed from the washing device, plates would wash quickest in apparati giving the steepest curves. The experiments with dyed plates proved that this was not always the case. The tests with these plates are tabulated below.

(Experiments shown in Plate 4.)

Fig. 1.—Water delivered at 81 litres per hour, falling on centre of lantern-plate in ¼-plate dish. Plate, colourless in 30 minutes. Prints (*a*) and (*b*) after 12 and 17 minutes respectively.

Fig. 2.—Ditto, falling on centre of long side of ¼-plate dish and issuing at opposite side. Plate, colourless in 38 minutes. Prints (*c*) and (*d*) after 16 and 30 minutes; and

Ditto, falling on centre of short side of dish. Clear in 30 minutes, and print (*e*) after 20 minutes.

(Experiments shown in Plate 5.)

Ditto, falling on lip corner of dish, plate colourless in 34 minutes, prints (*f*) and (*g*) after 15 and 25 minutes.

Fig. 1.—Water falling on centre of ¼-plate at 81 litres per hour, plate supported directly under stream, *i.e.* not in dish. Plate colourless in 30 minutes, print (*h*) after 20 minutes.

Fig. 3.—Five plates were placed in a 15 by 12 dish, with water at 81 litres per hour falling on centre of short side, the times of washing indicated in figure.

Fig. 2.—Circulating device delivering 116 litres per hour into corner of short side of a 15 by 12 dish. Plates washed clear as indicated.

Fig. 4.—Ditto, device situated on centre of short side.

(Experiments shown in Plate 2.)

Fig. 1.—Water at 81 litres per hour falling into catchment trough of continuous siphon tank. Tank held six plates, of which D_1 and D_6 were inner members, whilst the emulsion of D_2 was exposed to the open water next to the siphon. Prints (*j*), (*k*), and (*l*) were made after 28 minutes, and (*m*) and (*n*) after 42 minutes. All were colourless in 60 minutes.

Fig. 2.—Intermittent siphon tank. This device yielded prints similar to the above, the grading being a little more pronounced.

Fig. 3.—River washing device. The working of this apparatus is sufficiently indicated by the diagrams. Water was admitted at the top end at 81 litres per hour, and flowed from A to B in a thin uniform stream with a velocity of 3 cm. per second. As these conditions could be reproduced with accuracy, they were adopted for standard comparison purposes, strips 1 in. by 3¼ in. of all plates used being dyed and washed thus. The ratio of the time of washing of the strips to a standard time of 30 minutes was used as a factor to adjust the slight differences between one plate and another.

The relative washing power of most of the devices differed so widely from their water-changing constants that it would seem

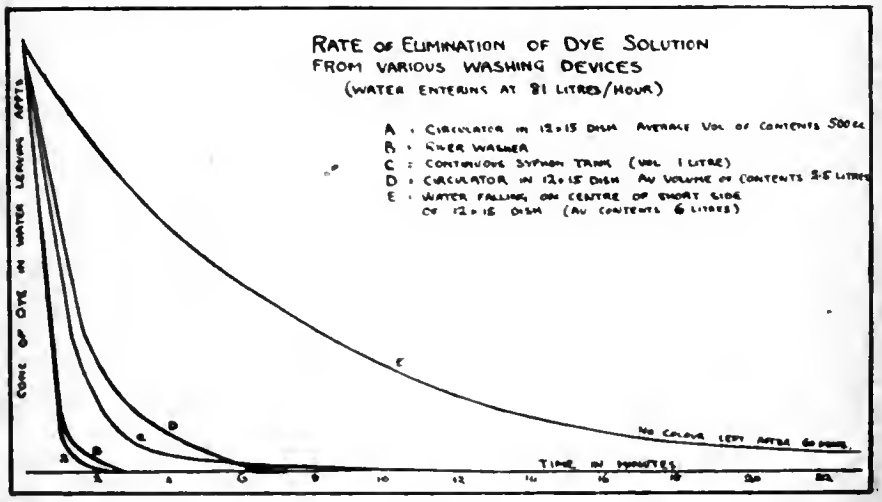

Plate 3.

that the mere quantity of water presented to the plate bore little relation to the time of washing. Thus, plates washed as in Fig. 3, Plate 5, where the conditions are of the worst, cleared in approximately the same time as those treated as in Figs. 1 and 2, Plate 2, though in the latter case complete change was presented to the plate every ten minutes. The most rapid washing took place under conditions illustrated in Figs. 2 and 4, Plate 5, although the incoming water is contaminated with stale solution before meeting the plate.

These anomalies can be accounted for on the assumption that conditions of flow past the actual plate surface are of paramount importance. The mere changing of water, unless this water is driven into intimate contact with the plate, would seem to have little effect. In support of this view, tartrazine-dyed plates were soaked in successive changes of water (*a*) in a mechanically rocked dish, (*b*) the same dish stationary. Five minutes was allowed for each soaking, complete draining taking place between the changes. (*a*) Washed clear in 25 to 30 minutes, while (*b*) was abandoned after 17 changes of water (85 minutes). Comparison between plates (*a*) and plates treated as in Fig. 4, Plate 5, revealed little difference. Yet in the case of (*a*) for the greater portion of each five minutes dye has been diffusing out into wash water in which partial equilibrium is already established. Mechanical agitation of the wash water is thus of supreme importance. Two experiments with the river washer confirmed this. A tartrazine plate was cut into two: one half was placed in the washer when the latter was working normally, *i.e.* with 81 litres per hour, stream velocity 3 cm. per second, and washed clear in 30 minutes. The washer was then tilted so that the stream thinned and accelerated to 12 cm. per second, the volume delivered remaining constant. In this case the plate washed clear in 25 minutes. The stream depths were 0·4 cm. and 0.1 cm. respectively, 0.1 cm. being the thinnest film which would cover the plate. The water used was large in comparison with the gelatine film, so that the dye had the opportunity in each case of diffusing into water of approxi-

2. Cassella. Pure crystalline. Commercial powder was unsuitable.

mately zero contamination. The divergence in washing times suggests an adherent layer of ejected molecules, thin in comparison with the stream used, and which requires vigorous agitation to remove (Fig. 5, Plate 6). Bearing this in mind, a multitude of water jets

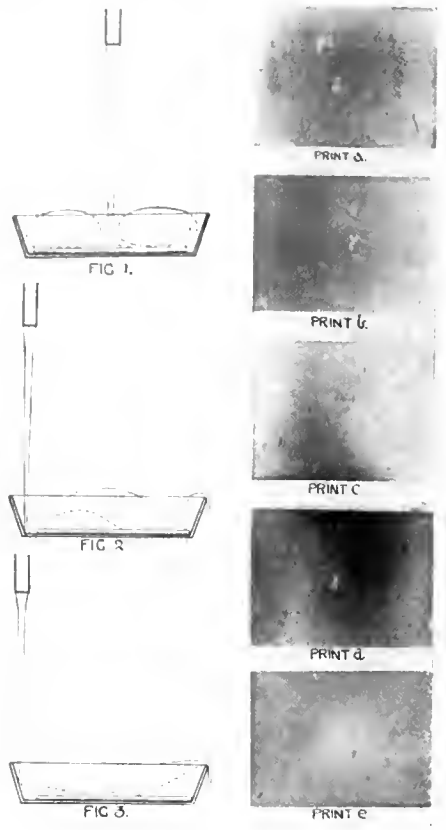

Plate 4.

from a perforated plate was allowed to impinge on to a dyed plate with as great a velocity as the latter would stand (Fig. 7, Plate 6). The concentration of dye in the wash water was literally zero, and any surface film was instantly dispersed. The time of clearance was shortened to 20 minutes. (This device was used in Experiment 2.)

Photo-Mechanical Notes.

Rotary Intaglio Printing Machine without Doctor.

A recent patent specification, No. 180,218, of 1921, by T. Ruddiman Johnston, of 13, Mikawadai-machi, Azabu-Ku, Tokyo, Japan, describe a machine for rotary intaglio printing, in which the sharp "doctor" blade is replaced by a thick cleaning bar. It is claimed by the patentee that the invention will make it possible to run rotary intaglio printing machines at a higher speed, and yet produce as good a quality of work, and much time will be saved by having an ink remover that does not require to be sharpened.

Fig. 1 is a side, and fig. 2 an end elevation of the improved ink remover and its parts, and fig. 3 is a side elevation of the piece employed to remove the surplus ink.

a^1 is a printing cylinder carrying either an iron sleeve with an etched copper surface, or an etched copper plate as described in Patent No. 117,888 of 1918 ("B.J.," 1918, September 27, p. 439). b^1 is the inking roller running in the ink trough b^2. c^1 is a shaft supported at both sides by the pillars c^2. On this shaft, and opposite the etched plate, is secured the carrier c^3, into which is inserted the piece of metal c^4 which removes the surplus ink. On the ends of the shaft c^1 are placed the pieces c^5, the sockets c^6 projecting from which carry the rods c^7, and sliding on these rods and capable of being secured at any part of them are the weights c^8. By moving the weights along the rods the ink remover can be forced with any pressure desired against the face of the cylinder or plate.

As a short reciprocating movement is given to the shaft c^1, and consequently the ink remover c^4, the pieces c^5 carry feathers which slide in grooves in the shaft, so that the latter may pass through

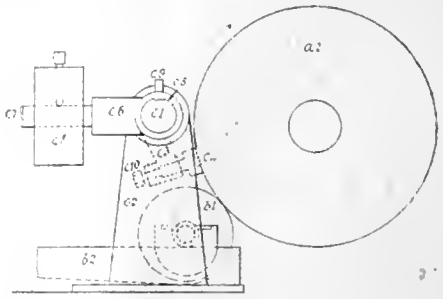

Fig. 1.

them without interfering with the action of the weights, these pieces being retained in position by the small parts c^9, which are secured to the pillars, and have their ends projecting over the raised parts of those pieces.

c^{10} are screws which pass through the carrier c^3 and bear against the ink remover to adjust the latter should this be found necessary.

When an etched copper-deposited sleeve or an etched plate has been printed from, and another has to take its place on the cylinder, the ink trough b^2, with the inking roller b^1 is pulled back, and the weights c^8 having been removed from the rods c^7, the carrier c^3 of the ink remover can be turned away from the cylinder's surface.

The part which removes the ink is made of an anti-friction or other metal that can be cast or ground to exactly fit the printing cylinder's surface, the invention being in using in rotary intaglio printing machines of a blunt, rigid surface resting accurately against the cylinder's face for removing the surplus ink, instead of employing the thin sharp flexible blades now in general use.

As it is possible that a small particle of a gritty nature may occasionally be carried by the ink beneath the ink remover, and scratch its surface, fine parallel grooves are made in the working face of the latter, so that such particles, should they pass its first raised portion, will lodge in the groove and do no further injury, but several grooves are shown to make certain that any such particles will not injure the entire face of the ink remover.

The printing cylinder may occupy any position relative to that of the impression or paper-carrying cylinder, and the ink remover

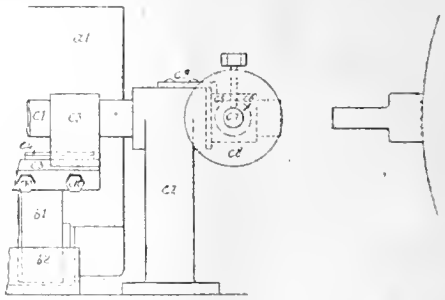

Fig. 2.

Fig. 3.

may be supported either as shown, or directly from the side frames of the machine, the invention being confined to using a blunt metal bar for removing the surplus ink, and not including anything else connected with intaglio printing.

The patentee's attention having been called to a patent No. 3,918 of 1873 (Monkhouse), as bearing to a certain extent on the invention, as this specification cannot be seen in Japan, anyone interested will require to consult it, especially lines 12-18 of page 5.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, June 12 to 17 :—

PHOTOGRAPHY.—No. 16,321. Photography. E. J. Clifford.

MOUNTING.—No. 16,608. Mounting photographs. A. F. Dufton.

COPYING.—No. 16,788. Process for photographically copying line drawings, letterpress, etc. E. Loening & Mimosa Akt.-Ges.

COLOUR PHOTOGRAPHY.—No. 16,242. Colour photography. F. B. Dehn (Pyrocolour Corporation).

TELEGRAPHIC TRANSMISSION.—No. 16,530. Method of transmitting pictures by telegraphy. R. S. Clay.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

STEREO-CINEMATOGRAPHY.—No. 178,344 (January 27, 1921). Two cinema cameras of single objective type are hinged or pivoted together, their mechanism arranged to work in synchronism, and provided with a racking device for readily and accurately controlling the inclination of the cameras, so that in varying their inclination they may be set with their central axes converging on to one and the same point at any desired distance from the camera apparatus. A calibrated scale is provided which indicates the distances from the camera at which the converging central axes intersect one another.

When the apparatus is used with the central axes parallel or so slightly converging that they do not intersect in front of the nearest object photographed, the negative pictures may be masked by means of masking plates inserted in the film gates of each camera in such a manner that the centres of the apertures in the masking plates are at variance with the longitudinal centres of the films respectively, so that a portion of the view is restricted on the left-hand side of the one picture and on the right-hand side of the next following picture, as described for double projectors in Patent No. 177,916, and for stereograms in Patent No. 9736/13.

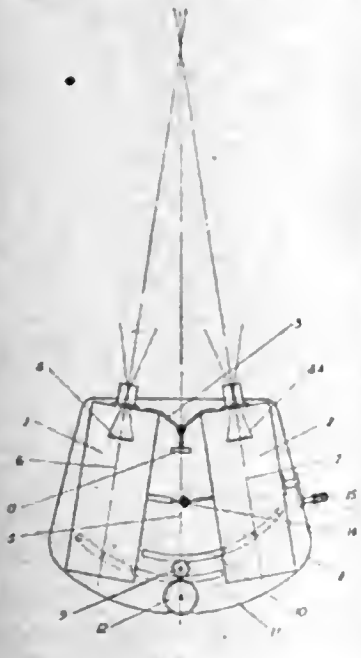

Fig. 1.

In fig. 1, 3 represents the hinge with wide flanges and the knuckle turned slightly back from the front of the cameras, so that, by increasing the inclination of the cameras 1 and 2 the separation of the objectives is reduced.

The two cameras 1 and 2 are mounted on a common base board 4 and the knuckle pin of the hinge 3 is continued into the base board and is fixed thereto. The hinge 3 is of the type known as loose butt, so that the hinged cameras may be removed from the knuckle pin; 5 represents the centre line of the apparatus which is consistently the bisecting line of the angle of convergence; 6 and 7 represent the central axes of the objectives for the two cameras coinciding respectively with the longitudinal centre of the vertically progressing picture films 8 and 8^A and perpendicular thereto.

A pinion 9 and twin racks 10 and 11 comprise a device for inclining the cameras simultaneously in relation to the centre line 5. The outer rack 11 of the racking device, also operates an indicator dial 12, on the circumference of which appears a scale indicating the distances from the camera apparatus at which the converging central axes 6 and 7 intersect one another on the centre line 5 when the inclination of the cameras is varied by means of the racking device. The pinion 9 is terminated in an operating knob beneath the base board 4. The base board 4 is supported and pivoted on a substantially constructed tripod, so that the apparatus may be rotated.

At the top of the hinge knuckle pin is fixed a view finder 13 of known type, set in alignment with the centre line 5. The driving spindles of the two cameras are connected together by means of a suitable universal joint 14, so that their mechanisms are driven in synchronism from one operating handle 15.

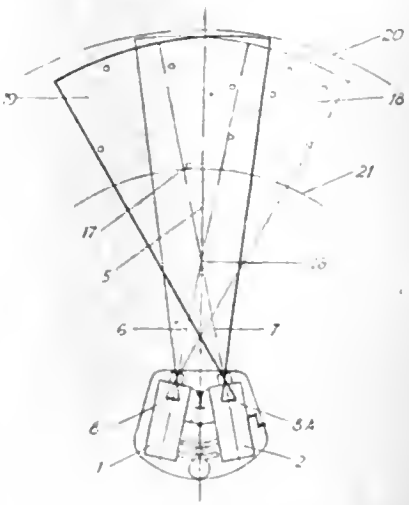

Fig. 2.

The cameras 1 and 2 are inclined towards one another, as shown in fig. 2, until their central axes 6 and 7 intersect at a point 16, on the centre line of the apparatus, in this case, nearer to the camera apparatus than the nearest object 17 in the photographic field of view. Thus the left eye picture 8 will embody images rightward 18 which do not appear in the right eye picture 8^A. Similarly, the right eye picture 8^A will embody images leftward 19 which do not appear in the left eye picture 8.

The arcs 20 and 21 represent the approximate depth of the photographic view.

The method of arranging the sequence of the exposures and dealing with the negative picture films in the production of the positive picture film is that in which the pair of negative films are produced with the exposures following one another without interspaces. The positive picture film is then made from the two negative films by leaving unexposed interspaces when printing from the one negative film and by exposing upon these interspaces when printing from the other negative film.—Sidney Hockley, 51, Dora Road, Wimbledon Park, London, S.W.19, and Archibald Slater Wilmot, 41, Tofnell Park Road, Tufnell Park, London, N.7.

DEVELOPERS.—No. 154,193 (October 23, 1918). In the course of experiments to determine the influence of substituents in the nucleus in the known amido-phenol or amido-cresol developers in respect of their developing properties, the patentees have discovered that the accession of the carboxyl group completely nullifies the developing capacity of the basic substances so long as the operations are carried out with sodium sulphite and sodium carbonate or potassium carbonate. By dissolving the developer in water and adding potassium carbonate, the carboxyl groups are certainly converted into their alkaline salts, but this procedure does not result in the production of a developing solution. In order to restore to solutions containing carboxyls their original developing properties, the hydroxyl-groups are, according to the invention, more or less completely converted into their alkaline salts by the application of free caustic alkali. Only by this means are the developing properties, which the presence of the carboxyl-groups had nullified again restored; but they are then re-established in a different character, and at the same time, in an enhanced degree of effectiveness. If only a part—say 25 per cent.—of the hydroxyl-groups present be neutralised with free

alkali, a slow acting developer is produced; whilst, if, say 50 per cent. of the hydroxyl groups present be neutralised, the developer produced is normal in its action. The complete neutralisation of the hydroxyl groups serves, however, to impart to the developer the characteristic of rapid action. Broadly speaking, the carboxyl group forms, as it were, a means of predetermining and regulating the developing properties of the solution as regards speed of action.

Moreover, seeing that other favourable qualities, from the point of view of technical photography, are obtained, the accession of the hydroxyl groups affords valuable advantages and constitutes a great advance in relation to the developers hitherto employed. Particularly is this the case as regards the power of the improved developers to compensate for the most diverse defects of exposure, more particularly for highly excessive exposure, which may be allowed to be 100 times the normal. The improved developers show no tendency to fogging effects; nor even to the yellow stain hitherto invariably resulting from prolonged development. According to the degree of dilution of the developing solution, the silver deposit exhibits a colour varying from black to brown, a specially valuable property for transparencies or photographs taken on gas-light papers. The developers do not stain the hands, and possess all the advantages and none of the disadvantages of the popular pyro developers.

The following examples are taken from the amidosalicylic-acids treated with hydrochloric acid :—

A stock solution of amidosalicylic acid of a two- or three-fold degree of concentration may be prepared in the following proportions :—

Amidosalicylic-acid	100 gms.
Sodium sulphite, free from water	500 gms.
Caustic lye of 5-times normal strength (200 gms. pure caustic soda per litre)	210 ccs.
Water	4,790 ccs.

Five litres of a stock solution (S), which may be preserved indefinitely, is thus produced. For developing purposes this solution is diluted with an equal or a double volume of water and then reacted on, according to requirements with the following proportions of ordinary soda lye :

Solution 1.—For over-exposure or for slow action; solution S. 50 ccs.; water 50 ccs.: normal caustic soda 3 ccs.

Solution 2.—For normal exposure and quicker action; S. 50 ccs. water 50 ccs. normal caustic soda 5 ccs.

Solution 3.—For normal exposure and rapid action; S. 50 ccs. water 50 ccs. normal caustic soda 7 ccs.

Solution 4.—For under-exposure and rapid action; S. 50 ccs. water 50 ccs. normal caustic soda 8 ccs.

Solution 5.—For enlargements; with normal action; S. 50 ccs. water 50 ccs. normal caustic soda 10 ccs.

Solution 6.—For enlargements, with quick action; S. 50 ccs. water 50 ccs. normal caustic soda 12 ccs

According to requirements, these proportions may be still further varied for special purposes. If the solution (S) be, for example, more strongly diluted the result is a slower development with brown tones. From gradual neutralisation, after repeated developing, the lye becomes exhausted of its reactive properties and must therefore be restored by addition from time to time so that the developing solution may recover its original efficacy.—J. Hauff & Co., 333, Stuttgarter Strasse, Feuerbach, near Stuttgart, Germany.

[Reference is directed by the Patent Office to Specification No. 1,736 of 1891, viz., that of the Actien Gesellschaft für Anilin Fabrikation, by which the latter firm's "Rodinal" developer was protected. From this reference it is to be assumed that in the view of the Patent Office the present invention of J. Hauff & Co. is wholly or partly anticipated by that described in the cited specification.]

Light-Sensitive Viscose Materials.—No. 178,942 (January 26, 1921.)—The invention relates to a process for the production of sensitive transparent viscose (cellulose) films for photographic purposes.

In order to sensitise, for photographic purposes, transparent films which do not resist water, especially certain cellulosic films for example cellulosic films obtained by recovering cellulose from an aqueous solution of sodium cellulo-xanthate) an aqueous solution has heretofore been used as a preliminary bath with the object of causing the film to swell, and of enabling the sensitising substances to penetrate into the interior of the film.

The object of the invention is a process based on the treatment of the viscose in a preliminary bath of an aqueous solution of one of the salts required for the treatment.

In order to produce a bromide film two baths are used; one of silver nitrate, and the other of potassium bromide. To produce sensitive silver bromide within the interior of the cellulosic film in an absolutely satisfactory manner under these conditions, it is necessary that the concentration of the precipitating bath should be molecularly equal to, or higher than the concentration of the solution which impregnates the film after leaving the first bath. Proceeding in this manner, and taking care to drain off the excess of the first bath, a deposit is obtained which is entirely in the interior of the film, and which does not diffuse in the precipitating bath, the latter remaining limpid; whilst the film retains a glossy and homogeneous aspect; results which could not be attained if the second bath were more dilute than that described above.

For example, if the dry film be impregnated with a solution of silver nitrate containing 10 gms. per 100 ccs., the potassium bromide bath employed for producing the silver bromide should contain in 100 ccs : $10 \times \frac{119}{170} = 7$ gms., at least, of potassium bromide the molecular weight of which is 119, that of silver nitrate being 170. On the other hand, if the first bath consists of an aqueous solution of potassium bromide containing 7 gms. per 100 ccs., the second precipitating bath of silver nitrate should contain at least 10 gms. of silver nitrate per 100 ccs.

By varying time of exposure, dilution of the developer, time of development and the like, cellulosic films which have been sensitised by pure or mixed silver halogen salts of very fine grain, will give a range of results as regards warm and cold tones, provided the films which do not resist water have a very fine grain obtained without ripening or by only carrying the ripening to a certain stage.

In other cases the sensitiveness thus obtained is not sufficient. It is, therefore, necessary to use a ripening process.

If the cellulose impregnated with silver nitrate in a cold aqueous solution is immersed for merely a few seconds in a weak solution of potassium bromide, a silver bromide of very fine grain is obtained which constitutes an unripened salt which is insufficiently sensitive. The sensibility of these silver cellulo salts is increased :—

By using—other conditions of time and temperature being equal—more concentrated solutions of either the silver salts or halogen salts or both;

By carrying out the operation at higher temperatures:

By prolonging the time of the action of the precipitating bath either in the cold or in the warm, acting in this case either on a large quantity of the bath, or simply on the small quantity retained by the cellulose by simple impregnation:

By impregnating the cellulo-salt already formed with a solvent of the cellulo-salt, and by taking precautions in this case to presaturate this solvent with the same silver salt with the object of preventing the salt formed in the cellulose from being dissolved;

By adding a suitable ripening agent, such as iodised silver nitrate or ammonia to one or to both baths;

By combining the halogenated salts in suitable proportions so as to produce for example an iodo-bromide of silver.—Jaques Edwin Brandenburger, 16, Rue du Louvre, Paris.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Latest date for entries, July 22. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition

of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for Entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

CROYDON CAMERA CLUB.

Mr. B. J. Rose on "Home-made Toys" filled last week's informal meeting. As with other photographic societies, Croydon possesses a floating rank and file out of which, from time to time, personalities are revealed in temperament, thought, and pursuits. Mr. Rose has long since so emerged.

Cheerful optimistic views are held by him on life in general, officialdom excepted, and he is especially strong on the home, and in particular the right way to deal with domestic servants, which includes many valuable recipes for converting the trial and tribulation variety into blessings of the seldom-met-with order. His special photographic bent is pinhole photography. Fond of debate, he has a delightful way of earnestly entreating the other side to take a common sense view of things, which invariably coincides with his own opinions.

Mechanically, he is a marvel in producing elegance from the dust-bin, so to speak, and the various ingenious toys passed round, constructed out of odds and ends, should make him a prime favourite with our little people. Of such stuff is parental greatness made.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given, pursuant to Section 242 (5) of the Companies (Consolidation) Act, 1908, that the names of the Arcade Studios, Ltd., and the Portsmouth Photo Co., Ltd., have been struck off the Register of Joint Stock Companies, and the companies are dissolved.

A PHOTOGRAPHER'S VARIED CAREER.—At the London Bankruptcy Court last week, the public examination was held of Henry Spencer, of 179, Archway Road, Highgate, photographer. The statement of affairs showed unsecured liabilities amounting to £3,287 8s. 2d., and assets consisting of shares in Spencer Enterprises, Ltd., which the debtor considered were of no value, thus showing a deficiency of £3,287 8s. 2d.

The Official Receiver's report upon the case was to the following effect:—

The debtor for about twenty-two years prior to 1896 resided on the Continent and dealt in horses, building material, etc. He also drove a cab in Paris, was a photographer, and, for about twelve months, the proprietor and editor of a paper published in Paris. For two years from 1896, he was employed as a canvasser and collector in the photographic business in Wales. He then opened a studio in Barry, and carried it on for about four years. He then returned to the Continent for two or three years and dealt in ships' stores, etc., in Antwerp. In 1899, he, in partnership with another person, opened a photographic studio in Northampton, but left that business in 1900 and came to London, where he carried on a similar business for about two years in Ball's Pond Road, N. For about eighteen months from 1902 he was in the employment of a firm of photographers, managing a branch in Chatham, where photographs were sold on a weekly payment system. In about 1903 he opened offices in Birmingham, where he commenced a similar business. In August, 1904, he formed "The Midland Counties Photo. Co., Ltd." to take over his business, and he became managing director of the company, which traded until 1905, when it went into liquidation. In 1905, he opened a photographic studio in Princes Street, Edinburgh, and carried it on for about twelve months, when he sold it. In 1906, he opened a similar business in Dundee, where he carried it on for about twelve months. In 1907 he commenced business in Glasgow as a business agent. He also conducted a photographic studio there, and an agency for the sale of tea. Judgments were obtained against him and he left Glasgow. In 1909, he, in partnership with another person, opened a photographic studio in Hanwell, but six months later he sold his interest to his partner. Thereafter, until September, 1911, he travelled about the country taking photographs, and during that period he lived at Wolvertou. He then became debt collector for a dentist, and in January, 1912, opened and was manager of a branch dental surgery at Croydon. In January, 1913, he opened and managed another branch at Bridgwater, which was afterwards taken over by a company in which he had 100 £1 shares, and which he continued to manage until September, 1914. He then commenced a photograph enlargement business by canvassing from New Southgate, but left there at the end of 1915. From about Christmas, 1915, he was in the employ of dentists in Kettering as outside organiser and collector until September, 1916. He was employed until early in 1917, when he obtained similar employment with a dentist in Hammersmith, with whom he remained until early in 1920. For about three months, early in 1920, he, in partnership with another person, carried on business as house agents at 36, Bridge Street, Hammersmith, under the style of "Martin's Agency." In about June, 1920, he commenced business under the style of "The Spencer Picture-Framing and Portrait Enlarging Co.," at No. 57, Kensal Road, Westbourne Park, W. In October, 1920, he moved to No. 179, Archway Road, Highgate, N., where he continued the business until it was taken over by "Spencer Enterprises Ltd.," in January, 1921. He and his wife were the only directors of the company, until an order was made for its compulsory winding-up on April 11, 1922. For a short period he also dealt in gramophones, under the style of the Porta-Gramophone Co.

In response to advertisements for "managers," various persons paid him sums of £200 or £250, and were appointed by him managers of branch photographic businesses opened at different places throughout the country. On March 28, 1922, he registered the London and Continental Enterprises, Ltd., of which he and his wife were directors, to make enlargements of photographs, etc., and to carry on business at No. 179, Archway Road, Highgate, N.

He attributed his insolvency to difficulty in securing suitable premises and having to pay the salaries of "managers" without premises for them to manage, to general unemployment and slackness of trade, to liability in respect of cash provided by managers and to ill health. The following deficiency account, dating September 1, 1920, has been filed:—

	£ s. d.
Liabilities assumed by Spencer Enterprises, Ltd., for which he is also held responsible	3,266 13 2
Household and personal expenses	370 15 0
	£3,637 8 2
Deduct:—	
Net profit from September 1, 1920, to January 11, 1921, when the company took over the business, £150	
Remuneration as managing director of Spencer Enterprises, Ltd., £200	350 0 0
Deficiency as per statement of affairs	£3,287 8 2

Of the unsecured liabilities, £2,849 15s. 2d., represented cash provided by managers, plus arrears of salary, interest, etc., £221

10s. 5d., rent, gas, electric light, etc., £120 cash advanced, £44 3s. 7d., goods supplied and work done, £31 4s. taxes and £20 15s. personal debts.

The "contingent liability" is in respect of a guarantee given on behalf of his wife who carried on business as a photograph enlarger, at 57, Kensal Road, Westbourne Park, W.

The debtor stated that the household furniture belonged to his wife.

The examination was closed.

NEW COMPANIES.

Howcrofts, Ltd.—This private company was registered on June 16, with a capital of £500 in £1 shares. Objects: To acquire the business of Florence Howcroft at 74, Blackburn Road, Bolton, and to carry on the business of dealers in photographic goods, etc. The first directors are: Frank Howcroft, 74, Blackburn Road, Bolton; Mrs. Florence Howcroft, 74, Blackburn Road, Bolton; and N. Hulme, 314, Blackburn Road, Bolton. Qualification: 1 share. Secretary: F. Howcroft. Registered office: 74, Blackburn Road, Bolton.

News and Notes.

Dallmeyer Lenses.—Messrs. J. H. Dallmeyer, Ltd., have received information from Mr. Hinks, Secretary of the Royal Geographic Society, that the two photographs of Mount Everest taken by members of the Mount Everest Expedition, which appeared in the "Daily Mail" dated the 19th inst., were taken with telephoto lenses of their manufacture. The cinematograph cameras taken out by the expedition early this year were fitted with Dallon telephoto lenses.

Photography at the R.A.F. Pageant.—One of the most interesting of the events at the Royal Air Force Pageant, held at Hendon last Saturday, was a photographic competition, in which the pilot had to take an aerial photograph of certain landmarks in the vicinity of the flying ground, the winner being the pilot who got his objective nearest the centre of the negative. Six different air stations took part in this competition, and negatives were developed in a mobile R.A.F. lorry, prints taken off them, and sold to the public on the ground.

Deciphering Burned Records.—Records charred beyond recognition in a fire at Augusta, Ga., have been made legible by the Bureau of Standards. Chemical means failed, so Raymond Davis, chief of the photographic laboratory, laid the charred sheet between two photographic plates with the emulsion side next the paper. After two weeks of contact, the developed plates gave a plainly readable record. Where there was contact between the charred paper and the plate, the latter was affected, but where the ink had been the chemicals of the plate were unchanged.—"Scientific American."

Quick Press Photography Again.—The London afternoon newspapers of 21st inst. contained excellent reproductions of photographs taken during the same morning at Plymouth on the occasion of the return of the Prince of Wales on board the *Renown*. The photographs were taken at about 10 o'clock, dispatched from Plymouth by aeroplane at 10.35, and reached Hendon at 12.35—220 miles in two hours. The plates were delivered by motor-car to the Central News at their office in New Bridge Street at 12.55, and at 1.30 this firm supplied a newspaper office with finished prints, and newspapers containing half-tone reproductions were very soon on sale.

Photographic Portraits for Election Purposes.—"Modern Electioneering Practice" is the title of a new thirty-five shilling book published last week. One of the writers is Mr. H. J. Houston, who is well qualified to write on such a subject, he having won elections in the face of fearful odds. Of photography he says:—"A great deal of care should be taken to make the portrait poster as effective as possible. If there is not a thoroughly reliable lithographic or photogravure printer in the division the work should be sent to London. No third-rate work should be tolerated at the expense of the candidate's features—not to speak of his chances with the women voters."

From Typing to Photography.—Changing jobs late in life was the subject taken up by the "Daily Chronicle" last week. The experienceof a short-hand typist is given in a letter:—

"Perhaps it may interest you to know that after 30 years as a shorthand-typist I have become a photographer. As a girl I was not able to get the training I wanted, but facilities for women who wish to take up photography are much greater to-day, and I found that after all the experience I had as an amateur photographer it was not difficult for me to learn enough to take up this fascinating art professionally. My age was a little against me at the outset, but once I was able to prove that I could take really good and distinctive pictures I was able to get employment, and I hope soon to set up my own studio."

Assistants and the P.P.A. Congress.—The Congress Council have set aside the Thursday evening in Congress week, September 14, as an assistants' evening, at which all photographers' assistants are invited to view the trade and photographic exhibitions. Music and refreshments will be provided and suitable interesting subjects discussed. The Council offer awards to assistants for the best window or show-case display of photographs, such displays to be arranged by the assistants competing, the size of photograph to be 12 x 10 in. unmounted, flat (not rolled). The competition will be judged at the Annual Congress, Princes' Galleries, Piccadilly, W.1, and all photographs submitted will be exhibited during that week. Photographs of windows or show-cases to be sent to the Secretary, Alfred Ellis, 2, Vinery Villas, London, N.W.8, marked "Assistants," not later than Thursday, August 31, 1922. All photographs must bear competitor's full name and address and the name and address of employers. Full details of the Assistants' Evening will be published later when the arrangements are completed.

Imported Picture Mouldings.—In the House of Commons on June 19 Mr. Galbraith asked the President of the Board of Trade whether he has received an application to impose a duty on imported picture mouldings; and, if so, in view of the uncertainty that exists in the picture and photograph frame trade, will he make an early announcement on this matter?

Replying, Mr. Baldwin said he thought it undesirable to give information regarding the nature or scope of any particular complaint unless it was referred to a Committee.

Mr. Kiley: "Does not the right hon. gentleman realise that when an announcement is made in a trade paper about application being made to impose a duty, it creates a certain amount of unrest and concern in that trade? Why cannot he make an announcement when he comes to a decision?"

Mr. Baldwin: "I do not agree with the hon. member. A great many announcements appear and are taken for what they are worth."

Mr. Kiley: "Did the right hon. gentleman not make a reference to the imposition of a duty on a certain article and to the import of that article, showing the results of such an announcement?"

Mr. Hogge: "Does my right hon. friend's answer apply to Government announcements?"

Mr. Baldwin: "I think the remark was of general application."

Correspondence.

COPPER TONING.

To the Editors.

Gentlemen,—The use of oxalates in the Ferguson copper toning process is not new, but is described by me in my paper of twenty-two years ago (Phot. Jour., xxiv., 135, 1900).

I found, however, that unless the water used was free from lime, and most town's water is not, a precipitate of oxalate of lime and cupric ferrocyanide was formed on and in the fibres of the paper, thus staining the whites. Some of this could be reduced by rubbing, and the rest cleared with hydrochloric acid, but that meant more washing and a tendering of the film.

The solution also if made with London tap water would not keep. Though clear at first it became muddy, and deposited in turn neutral oxalate of copper, and crystalline needles of potass caprie oxalate and oxalate of lime, and unless the toning were done at once and the dish well rocked these particles marked the film. The toning time taken was long; one hour for red tones.

All ammonia-copper compounds tried were found to stain the paper base, due probably to the action of the cuprammonium on the cellulose.

For the above reasons, I finally adopted the neutral potassium citrate as a solvent, which was perfectly satisfactory, and the mixture is now used—I believe literally in tons—for the toning of cinematograph films with the greatest success.

W. B. Ferguson.

BLUE SCREENS IN COPYING STAINED PRINTS.

To the Editors.

Gentlemen,—In reply to Mr. Venning's letter in your issue of the 23rd inst., may I state that my letter was based upon the experience of thousands of exposures upon wet collodion, ordinary, ortho and panchromatic plates, with screens ranging from almost colourless quinine sulphate solutions to powerful microscopic contrast filters.

Out of these exposures only a score or so have seemed to repudiate theory, but upon investigation these exceptions have in every case proved to be the result of some disturbing factor or circumstance not previously noticed. For instance, in one case a red screen (panchromatic plate) emphasised the apparently orange-coloured spots on a print. While seeking the reason for this unexpected result, I noticed that, viewed at certain angles, they had a decided green cast. A change to a green screen practically eliminated them. Possibly this bears some analogy to the instance of Mr. Venning.

I read his letter very carefully before writing, and did not suggest that the experimenting was an initial attempt at photography, but referred only to his colour work. As he neither described any details of the "nature of the stain" or characteristics which influenced his "choice of screen," I do not see why I should have been particularly impressed by them.

The inclusion of the yellow freckled client (I take it the word "cloud" in Mr. Venning's letter is a printer's error) cannot be objected to, as freckles in portraiture would equally conform to the same manipulations as spots in copying, which are really yellow, and not of the dichroic type referred to above, and commonly met with.—Yours faithfully,

J. F. Milner.

Bumberstone Road, Leicester.
June 26.

PHOTOGRAPHIC BUSINESS IN JAPAN.

To the Editors.

Gentlemen,—Since 1919 a steady increase in imports of British photographic apparatus and material has taken place, until to-day the public has a greater range of British goods to choose from than those from any other country. It is interesting to note, however, that during the past twelve months the Germans are once more securing a strong foothold with their cameras and lenses, due principally to the depreciation of their currency, enabling them to offer cheaper prices, and to the partiality of the Japanese consumer for German goods, brought about by the very efficient propaganda work employed by the Germans in pre-war days. Once more they are using the same tactics, and seemingly go to no end of expense in persuading the consumer that German goods "are the best." As an instance, there are several very attractive stands at the Tokio Peace Exhibition, displaying the wares of the leading German photographic manufacturers, whereas not a single British manufacturer is represented, except through having his goods displayed in the stands held by the leading wholesalers of the country.

The prosperity which Japan has enjoyed during the past few years has resulted in an enormous increase of both amateur and professional photography, and there is every indication that this interest has come to stay. Many one-time amateurs, imbued with the idea to "get rich quick," started up as photographic dealers, and as every merchant, however small, likes to be known as a "direct importer," it was soon found that the British merchants gave the best terms of payment.

American photographic manufacturers always demand payment by confirmed banker's credit; German manufacturers appoint German firms, established in this country, as agents, who in turn sell C.O.D., or sometimes on a P/N basis to approved Japanese wholesalers only, whilst many British manufacturers, believing the people they are dealing with to be as honest as themselves, very often finance by documents on acceptance.

Now, the above-mentioned "get-rich-quick" merchants are in the habit of using elaborate letter-heading for their foreign correspondence, and their letters, as a rule, are written in a fairly business-like manner, so that the receiver is often deluded into believing that it comes from a responsible source. At times, also, the sender will refer the addressee to one or other of the leading Japanese banks, who, if they are ever approached, will give a non-committal reply, but worded in such a way that one is led to believe the firm being inquired about is a perfectly responsible one. At first, more or less small orders are forwarded to the British firms, and on arrival of the goods the drafts are accepted and paid for, which gives further confidence to the shipper. Then our small merchant, who perhaps has been successful in selling his first two or three shipments at a profit, and has also obtained the confidence of the British shipper, forwards a much bigger order, stipulating it is to be financed D/A. Some do this with a mistaken idea of their ability as business men, whilst others do it with the deliberate intention of cheating the shipper. In either case, the effect on the British shipper is the same, as on presentation of the draft to the drawee, it is at once accepted by him, and the bank hands over the shipping documents, enabling the local merchant to secure control of the goods, and then, when the due date of payment of the draft comes along, the bank is simply informed by the drawee of the draft that, through bad market conditions, bad luck, or any other equally futile excuse, he is unable to meet his obligations. The bank then recovers all expenses incurred from the drawer, and more often than not the whole transaction means a total loss to the latter.

This, however, is only the beginning of the damage to the manufacturer. Once the importer has control of the goods, which have cost him nothing but landing charges and Customs duty, he is able to offer his wares at exceptionally low prices—so low, in fact, that the three or four legitimate wholesalers, who meet their obligations and trade in an honest, straightforward way, find it impossible to compete in price, and so decided to give up importing goods which small retail shops are able to buy direct from the manufacturer. Little or no recourse can be had through the Japanese Law Courts, as Japanese laws seem to have been especially promulgated to help a dishonest merchant to prosper. I am of the opinion that there are not more than four photographic importers in this country upon whom it is safe to finance either documents on payment or documents on acceptance. From all the others, British manufacturers and exporters should stipulate for payment by confirmed banker's credit, preferably the Yokohama Specie Bank's E Form Letter of Credit, or one issued by one of the foreign banks established in Japan.

Forgive me for taking up so much of your valuable space, but it is because I feel the British manufacturers do not realise existing conditions in Japan, that has induced me to place the facts before them, in the hope that they will be prevented from enriching many unscrupulous retail merchants at the expense of themselves, and further antagonising the large wholesalers (who in reality do the great volume of trade) against their wares.—Yours faithfully,

"Britisher."

SOCIETY PREMISES.

To the Editors.

Gentlemen,—I am informed that a number of photographic societies throughout the country have a room, or rooms, placed at their disposal by local municipal councils, either freely or at a preferential tariff. I should be glad if Hon. Secretaries of any such societies would please communicate their arrangements to me. My Committee intend approaching our town council, and such knowledge would be of great service to us.

I am, Gentlemen,
Yours faithfully,

W. T. Comer.

4 and 6, Arcade, Walsall.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S. S.—Impossible to say from the particulars. If you will send one or two of the defective prints we will see what we can do.

M. F.—Out of print, but no doubt obtainable for a shilling or two from Messrs. Foyle, Charing Cross Road, London, W.C.

X. X. N.—R. H. Bow died on February 17, 1909, at the age of 82. Many of his papers on photographic optics appeared years ago in the "B.J."

PERMUTE.—The booklet on the opportunities for outdoor portrait business, issued by Messrs. Sands, Hunter, Bedford Street, Strand, London, W.C., should give you the suggestion you want.

B. L. M.—Persulphate can be used as the reversing bath for Autochromes, but has no advantage over the usual permanganate formula. If you prefer the permanganate bath before re-use, you will not get spots. In first making up, dissolve the permanganate in very hot water, and add the sulphuric acid when the solution has cooled.

C. D. AND CO.—It is clear from what you tell us that the portrait was made in execution of an order given in the ordinary course, and therefore, as we have said scores of times in this column, the copyright is the property of the sitter. As regards copying it or ordering it to be copied, she can do exactly as she likes. You had better excuse your ignorance of this very elementary fact of copyright law in the best way you can.

T. E.—About the best way to repack plates after exposure is, first, to cut round the original wrapping of box across the middle. In repacking, all that is necessary is to replace the two halves of the cover, when a piece of adhesive paper, such as used for binding lantern slides or passe-partouts, stuck round where the cut was made, will join both cover parts together, and the plates are as secure and safe from injury as when first received from the makers.

K. Y. E.—Bromine solution makes a first-rate bleach in the sulphide toning process, but it is impossible in practice on account of the most irritating vapour which it gives off. Certainly the vapour itself might be used, its bleaching action being followed by the application of sulphuretted hydrogen gas. This pair of substances in solution provides an effective toning process, no washing between bleaching and darkening being necessary, but it would not be easy to work such a process regularly.

E. MENNY.—Ensyna was a silver phosphate paper made under the patents of York Schwartz. Nos. 9,993 of 1908, and 9,855 of 1907. The developer was issued under a patent (No. 13,032 of 1905) of J. H. Mallabar. The full specifications can be seen in the library of the Patent Office, 35, Southampton Buildings, London, W.C. Paget Phosphate and Wisto papers (the latter made by B. J. Edwards) were somewhat similar products. You will find a full account of all three in the 1910 Almanac, pp. 551-555.

P. E. N.—Perhaps the following formula for a dry ready-to-use amidol developer will answer your purpose:—

Soda sulphite anhydrous	30 gms.	1 oz.
Diamidophenol	5 gms.	80 grs.
Soda metabisulphite cryst.	50 gms.	1¾ ozs.
Potass bromide	3 gms.	45 grs.

These substances are pounded together with mortar and pestle until a fine powder is produced, and the mixture is stored in well-closed tubes. The above mixture is dissolved in water, 1,000 c.c.s. or 35 ozs.

F. N. T.—Some years ago the late Mr. Essenhigh Cooke made exactly the same suggestion. He showed the advantage which can be taken of a small pocket camera (the focussing scale of which does not extend beyond about 6 ft.) by using the instrument on a tripod and with the smallest stop in the lens. In this way objects much nearer to the camera than the shortest distance provided by the focussing scale may be satisfactorily copied and distant objects obtained on a larger scale by using the camera at its full extension and stopping down the lens.

A. E.—You certainly cannot photograph the dancers by flash-light when they are in movement, since that would mean an exposure of not more than about a 50th or 100th of a second, and a sufficient charge of flash powder will probably take at least a 20th of a second to burn. For a standing group, with the dancers in anything like the position which they occupy when in movement, you will probably have to stop down the lens to about *f*/11 or *f*/16, under which condition, when using an ultra-rapid plate, probably half an ounce of flash powder (Johnson's "Professional") will not be too much, especially if the building is a large one, so that you do not get much advantage by reflection by the walls.

J. SMITH.—The only thing of the kind which we can trace is a process described in a German patent, No. 201,968, of Tellkampf, in which a ferricyanide bleach is used for the production of a printing surface from which proofs in greasy ink may be taken. The ferricyanide-bleached print is applied to a gelatine film containing a ferrous salt (prepared from a mixture of 100 gms. of gelatine and 1 gm. of ferrous sulphate in 600 c.c.s. of water). The unaltered ferricyanide in the print combines with the ferrous salt, producing an insoluble salt in the gelatine, which, after this treatment, is able to absorb a fatty ink. From the relief film thus obtained, prints are taken off by contact.

H. H.—In almost all seaside resorts the local authority, the Town Council, or the local District Council, sells its rights for photography on the beach for (often) quite considerable sums, and therefore prohibits other persons from carrying on a photographic business on the beach. We think you will find that this is the case in most seaside resorts. In some places the police authorities require a photographer carrying on a while-you-wait business in the streets to have a pedlar's licence. Our correspondence shows that the requirements of the police in this respect differ greatly in different localities, but you may take it as certain that the possession of a pedlar's licence will not help you at all as regards carrying on your business on the beach.

F. D.—It is a considerable disadvantage not to have any side light available, but we think you can make a fair studio by glazing the greater part of the N.E. side of the roof. Have 4 ft. boarded over at C, and then 20 ft. run of glass and 5 ft. boarded over at the other end. This will give a fair amount of high front light. Is such a studio a large cheval glass may be used to give a certain amount of side light, with good effect. We assume that there are no side walls near the studio, which are of greater height than the eaves. There would be no object in having glass on the ends of the studio, except for "fancy" effects. You might put one sash, say 6 ft. square, at the end, and work across the studio sometimes, in which case it would be better to carry the glass right along to the end.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3244. Vol. LXIX. FRIDAY, JULY 7, 1922. Price Fourpence.

Contents.

SUMMARY.

A judgment last week in the Court of Appeal (reversing a previous judgment in the High Court) held that the "equitable assignee" of part of a copyright cannot by himself take action for infringement of the copyright which has been assigned to him in this manner, but requires either to obtain assignment in law before taking action, or, alternatively, to be joined with the legal owner of the copyright as co-plaintiff in any action for infringement. We quote the judgment from the "Times" on page 406, and in a leading article on page 398 refer to circumstances, in connection with copyright in photographs, in which the judgment would apply.

The method of extra-sensitising, worked out by M. F. Monpillard, has been applied by M. Gimpel to ultra-rapid ordinary plates, and has permitted of some shutter exposures of subjects under ordinary artificial illumination. (P. 399.)

In the concluding portion of their paper on the washing of negatives and prints, Messrs. K. C. D. Hickman and D. A. Spencer describe tests of further washing appliances, and also give a description of an ingenious pneumatic rocker for developing dishes. (P. 400.)

The Northern exhibition will be held next year in Manchester during February. (P. 402.)

Mr. A. C. Banfield recommends a reflex of 3½ x 2½ inches size as a most advisable choice for serious tourist photography. (P. 397.)

Two recent patent specifications describe photo-mechanical methods of making stencils for the manifolding machines used in letter copying, etc. (P. 402.)

Dr. B. Homolka has drawn attention to a new developer which gives an image of brown tone, due to addition of a reddish-coloured substance to the black silver deposit. (P. 397.)

The convenience of a metronome in the dark room and a use for empty spool bobbins are the subjects of "Assistants' Notes." (P. 402.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

M. F. Monpillard has at length published particulars of the method of greatly increasing the speed of Autochrome plates by extra-sensitising, which he worked out some years ago. (P. 25.)

M. L. Gimpel, who was a collaborator with M. Monpillard in the practical use of the process, has communicated to the French Photographic Society an account of his experiments and instructions for making up the dye sensitising solution, the new ingredient of which is a small proportion of silver chloride dissolved in ammonia. (P. 26.)

Mr. R. M. Fanstone gives a few hints on the making of Autochrome transparencies of garden subjects. (P. 28.)

Professor R. Kögel has drawn attention to a new class of dyes which, it is suggested, may revive the almost obsolete bleach-out process. (P. 28.)

Dr. A. Traube has published some particulars of his Uvachrome process, in which three-colour transparencies are made by dye-toning. (P. 28.)

EX CATHEDRA.

The Small Reflex. We are glad to endorse the recommendation of Mr. A. C. Banfield, made at a meeting of the R.P.S. Pictorial Group, of the 3½ x 2½ reflex camera as the choice of instrument for the serious tourist photographer. Mr. Banfield uses a Soho reflex of this size, finds it light and reliable, and is able to employ focal length of lenses from 4¾ to 12 inches, the former a Ross Xpres and the latter a Dallmeyer Dallon. We agree that the 60 x 45 m.m. size is on the whole too small. Mr. Banfield refers to the difficulty of ensuring the flawless negatives which are necessary in this size, unless the photographer is exceptionally gifted as a retoucher. To this objection may be added the further one that selective focussing becomes impossible with most subjects when employing a lens covering over a normal angle of view. Adopting the reflex in the size of 3½ x 2½ ins., the photographer is not inconvenienced by the bulk of the apparatus and as regards weight, by carrying 24 cut films in a changing box and a further dozen in dark slides, Mr. Banfield's whole load, including three lenses, did not exceed 10½ lbs.—more than some people care to carry in these unpedestrian days; but then the outfit has a wide optical range and provides for 36 exposures in the course of the day, whilst the negatives are usable for contact souvenir prints and are as suitable as can be desired for lantern slides.

* * *

Hydro-coerulignon Developer. In the Festnummer of "Photographische Korrespondenz" Dr. B. Homolka has an interesting note on a developing agent which he has discovered with properties analogous to those of indoxyl. The latter, it may be remembered from Homolka's previous paper (B.J., 1907, February 22, p. 136, and March 22, 1907), has the property of developing the latent image and of attaching to the silver image one of indigo, formed by oxidation of the indoxyl. In the present case the oxidation product, coerulignon, is of orange yellow colour, so that the compound image consisting of it and silver is brown in colour. The developing solution is made up by dissolving 5 gms. of potass carbonate and 10 gms. of soda sulphite with 1 gm. of hydrocoerulignon in 100 c.c.s. of water. The image appears in about half a minute, and development of either a plate or bromide paper is complete in 1 to 5 minutes. By treating the resulting compound image with an alkaline solution of sodium hydrosulphite, the coloured element is reduced and dissolved, leaving the ordinary image of black metallic silver. On the other hand, the use of the Farmer's "reducer" oxidises and dissolves the silver in the image, leaving one of the orange-yellow coerulignon. The results have an interest in their bearing on the theory of developers, but Dr. Homolka does not suggest that the developer is of practical usefulness, although its properties are more attractive in this respect than the blue-image indoxyl.

Reproducing Stained Films. It very often happens that a photographer is called upon to make a print or enlargement from an amateur-developed roll-film negative in which large yellow patches have appeared as a result of uneven fixation. This defect is usually due to the "pull through" system of development and fixing, when the film is usually put to wash immediately the unaltered bromide has disappeared. As no isochromatic bromide papers are on the market, it is necessary to reproduce such negatives. By using an isochromatic plate and yellow light a clean transparency may be easily obtained. If this is to be of the same size as the original, the exposure may be made through an ordinary yellow glass, or even by the yellow light used for developing bromide prints, but for enlargements or reductions a yellow filter, as used for outdoor work or copying, becomes necessary. It is sometimes possible to remove such stains by means of the cyanide and iodine reducer, but if this be not possible, or if the negative is of great value, the reproduction method should be adopted.

OWNERSHIP OF ASSIGNED COPYRIGHT: THE EQUITABLE ASSIGNEE.

A JUDGMENT last week in the Court of Appeal involved, as Lord Justice Bankes said in delivering it, questions of considerable importance in relation to the law of copyright. The original case had nothing to do with photographs, but the circumstances were those which could arise, and doubtless have arisen, in connection with photographs, and, therefore, it is well that we should attempt to express in a popular form the legal difficulties which were discussed. It will be seen that the judgment concerns ownership of copyright which has been split, and particularly the qualification of an "equitable assignee" of part of a copyright to take action in respect to infringement. If we first describe the circumstances of the case, its legal technicalities and the (abridged) text of the present judgment, which we quote on another page from the "Times," will perhaps appear less formidable.

The trouble all began with the singing at Collins's Music Hall, Islington, of two songs, "A Devonshire Wedding" and "Love in Lilac Time." Now the rights in the performance of one of these songs in public (as distinguished from publication in print, etc.) were claimed as their property by the Performing Rights Society, Ltd., who in 1916 had taken an assignment from Messrs. Chappell's, the music publishers, of the right of performance of all songs the right of performance of which belonged to them, and of all others which they might acquire. Similar rights in the other song were founded on a similar title derived from Messrs. Keith, Prowse and Co. Hence, when the songs were sung without permission at Islington, the Performing Rights Society, Ltd., took action against the proprietors of the music hall, the London Theatre of Varieties, Ltd., and in the King's Bench last December judgment was given in their favour by Mr. Justice Branson. It was then held that as "equitable assignees" of the two other companies the Performing Rights Society, Ltd., acquired the equitable title to the right of performing the songs as soon as the copyright of the songs came into existence; and it was also held that as "equitable assignees," though not legal assignees, they could take action by themselves, that is to say, without bringing in as co-plaintiffs the assignor firms who retained the remaining part of the copyright. In other words, so it seemed, no distinction was to be drawn between assignments in equity and assignments in law in interpreting the provisions in the 1911 Copyright Act respecting the right of an assignee to take action for infringement. Mr. Justice Branson seemed to regard the equitable assignee of part of a copyright as possessing a right in this respect equal to that possessed by a person to whom that part had been assigned by a specific legal deed. It is this decision which has been set aside, or at any rate revised, by the Court of Appeal.

For the opinion of Mr. Justice Branson did not appear right to the Court of Appeal. It would seem that the distinction between an assignment in equity and an assignment in law is too serious a thing to be trifled with. Consequently, the Copyright Act is scrutinised in order to see if it is reconcilable with the Court's view of the importance of this difference, even though the reconciliation does violence to the layman's conception of equity. Says the Court of Appeal: By Section 5 of the Copyright Act the owner of a copyright has the right to assign the whole or part of the copyright, provided he does so in writing. By Section 6 it is the owner who is entitled to all civil remedies for infringement. Hence—and this is the crux of the judgment—the first owner or any subsequent owner by legal assignment does not cease to be an owner (within the meaning of the Act) when he executes an "equitable assignment" of the whole or part of his right. From that view it follows either (*a*) that the "equitable assignee" is not an owner at all, or (*b*) that two owners are recognised by the Act in these circumstances, the legal and the equitable. The Court frankly admitted the difficulties in the way of accepting either conclusion from this train of reasoning, but of the two preferred (*b*), viz., that there are at one and the same time two owners of different kinds from the legal standpoint. It clothes this conclusion in less challenging language by saying that the term "owner" in the Act may be regarded as including "equitable owner." Hence, in any action for infringement, the "equitable owner" may not act alone, but must be joined with the legal owner; or, to put it in a more commercial form, if A enters into a general arrangement to acquire certain present and future rights from B, he cannot take action in respect to infringement of those rights, except with the help of B, who has ceased to have an interest in them. In the particular case, the judgment means that the original plaintiffs, if they so choose, can start all over again in conjunction with the legal owners of the copyright; if they do not so choose, the remedy provided by the Act for the infringement goes unapplied.

The judgment, however, by reason of the high order of the Court from which it comes, requires to be seriously considered in relation to copyright in photographs. In the first place, it underlines the necessity for a proper legal assignment in writing of the whole or part of a copyright, if the assignee (purchaser) is to be able to take action in respect to infringement "off his own bat." We infer, for example, that an arrangement between a postcard publisher and a photographer, by which the former should have the right to issue the latter's portraits in postcard form, would be an "equitable assignment" of the kind which was made in the case of the songs, and that the publisher, in the face of the judgment, would require to be joined with the photographer in taking action respecting infringement. While in such cases photographers, as the creators and assignors of copyrights, run no risks of suffering from the effect of the judgment, in other circumstances they may themselves be "equitable assignees," and thus find themselves handicapped in the protection of rights which they imagined they had fully acquired. For example, a

general undertaking may be entered into for the right to issue the existing and future works of an artist in the form of photographs. In the absence of a legal assignment of this part of the copyright in each individual work, the effect of the judgment, as we understand it, is to render the photographer powerless against piracies of his photographic copies, unless the original author of the works is willing to join in proceeding against the infringers. In short, while an "equitable assignment" of the kind illustrated by our examples suffices to determine the relation between the assignor and assignee, legal specific assignment by deed is required as a preliminary condition of legal action by the assignee; failing which, the legal owner of the copyright must appear with the equitable assignee as joint plaintiff in any action for infringement.

HAND-CAMERA NIGHT PHOTOGRAPHY ON EXTRA-SENSITISED PLATES.

[The following is part of a paper by M. L. Gimpel on the extra-sensitising of Autochrome plates which appears on another page in the "Colour Photography" Supplement. Here we place the portion of M. Gimpel's text which deals with the extra-sensitising of ordinary plates, and are indebted to the French Photographic Society for the loan of the blocks illustrating his use of the plates in photographing night subjects by the ordinary illumination.]

The use of the Monpillard ultra-sensitising process for plates for ordinary monochrome photography led me to discover the untruth of a statement which has always deterred me from making endeavours to use extra-sensitised plates for instantaneous exposures on night subjects. The "authorities" agree in saying that extra-sensitising by bathing can yield good results only with plates of medium speed such as the Lumière Blue Label, and that the process can only increase the sensitiveness of the plate to the less refrangible rays of the spectrum to the disadvantage of the general sensitiveness. In discussing this "fact" with M. Monpillard, we agreed that it would be useless to try ultra-sensitising experiments with the ultra-rapid Lumière Violet Label plate which I used exclusively for my Press work on account of its great speed. Nevertheless I thought to myself that it might be worth while

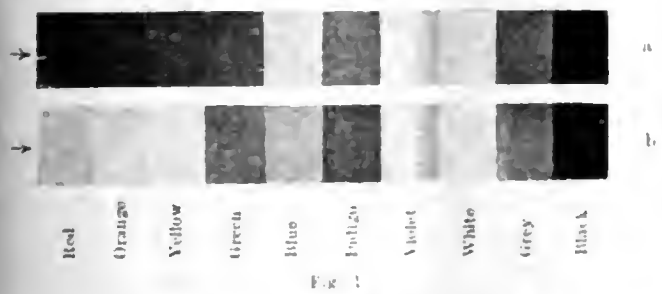

Fig. 1.

Fig. 2.

Fig. 3.

to try it. Practice is not always in accordance with theory, and, moreover, the process is something new.

I was fortunate, for of all the plates which I tried only the Lumière Violet Label gave me the interesting results which, in the most favourable circumstances, allow of shutter exposures by the ordinary artificial illumination of rooms or streets. The photographs (Figs. 1 to 4) will show the nature of these results better than a long explanation. Fig. 1a is of a coloured chart photographed on an ordinary Violet Label plate with an exposure of 20 seconds at *f*/64 by the light of two 25 c.p. lamps placed at a distance of about 10 inches, one on each side of the chart.

Fig. 2b was obtained with half the exposure on an ultra-

sensitised Violet Label plate. It will be seen that there is as great sensitiveness to the grey square, considerably more to the red and orange, and particularly to the yellow, to which latter the ultra-sensitised plate is 20 times as sensitive. The exposure corresponds with 1/25 of a second at *f*/4.

Fig. 2 is a photograph taken at a *fête* of Joan of Arc on May 4, 1913. The lighting consisted entirely of candles held by the nuns and fairy lamps hung in the trees. The exposure was 10 secs. at *f*/4 on an ultra-sensitised Violet Label Lumière plate.

Fig. 3 is an exposure, of a quarter of a second at *f*/4, made in a bar on the Boulevard St. Denis, lighted by neon and mercury-vapour tubes. The same plate was used.

In Fig. 4, again on a Lumière ultra-sensitised Violet Label plate, the subject was the Place de l'Opera on the occasion of the visit of the King and Queen of England on April 22, 1914. The exposure was 5 secs. at *f*/4.

[Other examples were shown by M. Gimpel, among them scenes from "Kismet," taken under the ordinary stage lighting.]

The ordinary ultra-sensitised plates keep somewhat better than Autochromes which have received the same treatment. They retain their properties for about 36 hours. The process of sensitising is exactly the same, except that the time of immersion is 5 minutes, on account of the greater thickness of the film. For the same reason drying is slower, but is complete in about 10 minutes.

For development I use my usual formula of metol and hydroquinone. Plates, of course, require to be handled with even more care than panchromatics, but those who wish can

Fig. 4.

work in ample yellow light by employing the safranine or aurantia desensitiser.

L. GIMPEL.

THE WASHING OF NEGATIVES AND PRINTS.

[A paper recently read before the Royal Photographic Society by Messrs. K. C. D. Hickman, B.Sc., and D. A. Spencer, A.R.C.Sc., entitled "A Constructive Criticism of Washing Devices and Optical Methed of Testing," has been printed in the Society's "Journal" as the first part of a comprehensive communication on this subject, It contains many experimental data bearing directly upon the practical methods of washing negatives and also prints. With much ingennity the authers illustrate side by side their experiments and the results obtained as regards unifermity and completeness of washing, and they describe their inventions for the washing of plates, among them one which has already been placed upon the market in the shape of the Hickman "Circulator." The paper certainly represents the most scientific experiments which have been made on the removal of hypo from gelatine films by washing, and are deserving of a close study on account of the great ameunt of practical information which it contains.]

(*Concluded from page* 390.)

It would appear, therefore, that to project water in a uniform current in the plane of the plate is not necessarily the most economical way of using it. It is advantageous to introduce cross streams and currents normal to the surface to give the freshly diffused substances a chance to escape. That even moderate disturbance of a uniform stream is beneficial was shown by washing two halves of a dyed plate in the river washer, (*a*) in the normal stream, (*b*) the same, but with a series of waves artificially maintained on the surface. Time of clearance was shortened by 3 minutes (Fig. 6, Plate 6).

An attempt was now made to apply the lessons learnt in the foregoing experiments to the production of an efficient apparatus for washing plates. It must combine the efficiency of the "successive change" method with the convenience of running water, and it must be attachable to any existing dish or trough. It should be automatic in action and should operate with a small volume of water in the dish, which it should agitate vigorously and irregularly, and change rapidly.

The following apparatus, while not so efficient with regard to water as demanded above, fulfils the other conditions. Fig. 2, Plate 6, shows a delivery pipe W placed over the edge of a photographic dish. A stream of water travels up the centre, branches at the top, and returns round the sides to the point of origin. Here it is picked up by a siphon Y attached to a suction pump. The apparatus acts efficiently because :—

(1) Fresh water enters with considerable velocity and makes a complete circuit of the dish before removal.

(2) Owing to the change of direction at the top, water is piled up at various points, and waves are projected and reflected in all directions (Fig. 1, Plate 6).

(3) The water in the dish is at a constant level, determined at will by the height of the outflow. By maintaining a small depth, many changes are obtained with little water expenditure.

The supply jet and exhausting siphon have been combined to form the improved apparatus shown in Fig. 3, Plate 6. The delivery tube passes through the head of the exit pipe, where it creates a partial vacuum by reason of a venturi constriction. With the lower bend of the outflow sealed with water, siphon action is initiated when the level of the water in the dish covers the exit holes. The action is automatic, and has been found to be satisfactory in practice. The "circulator" mentioned above refers to this device.

The following remarks serve to explain the results tabulated above.

Water falling into the centre of a small dish gives efficient washing because the changes are frequent, the relative dimensions enabling a convection vertex to be maintained (Fig. 1, Plate 4).

Dropping water on to the side of a dish to induce transverse currents has long been recommended, the course of the water being pictured as in Fig. 3, Plate 4. The actual course, revealed by coloured streams, is more as pictured in Fig. 2. Prints (*c*), (*d*). and (*e*) shew how unreliable the methed is.

The divergence from theory is most marked in the case of the siphon tanks, Figs. 1 and 2, Plate 2. In the light of these experiments this is explained by the stillness of the water, washing being rapid only in the region of the entrance holes. An important point is the tendency for the deposition of air bubbles on the film, owing to the water not receiving sufficient agitation after leaving the tap. (See prints J, K, Plate 2.)[9]

9. These spots are distinctly visible in the original prints.—ED.

The river washing device was capable of washing many plates in series, but its efficiency was disappointing except for the foremost plate. It was retained merely as a standard instrument of research.

In order to render the washing times for dyed plates of value to the practical worker, an attempt was made to correlate them with those obtained for plates washing free from hypo. This was accomplished in one case only, as in Fig. 3, Plate 5, with four plates in a 15 by 12 dish. The results were shown graphically in Figs. 1*a* and 1*b*, Plate 1. It is seen that the hypo diffuses roughly

FIG 1

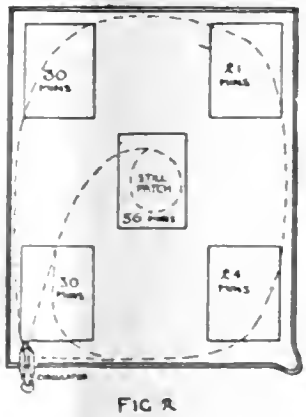

FIG 2

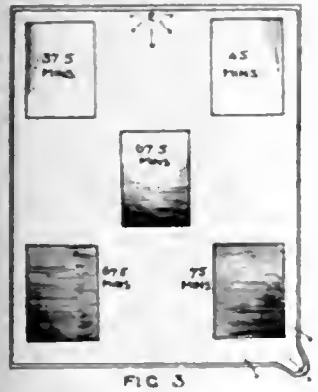

FIG 3

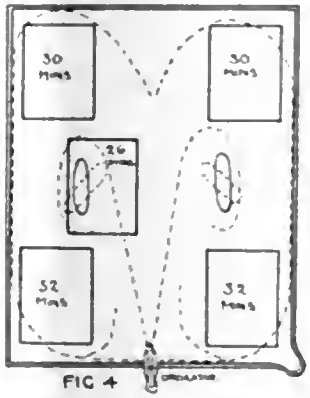

FIG 4

Plate 5.

ten times as fast as the dye in each of the four positions, though they correspond with very different conditions of water supply.

It must be borne in mind that the washing times, unless otherwise stated, are for one plate only in each apparatus. Where the water is being changed rapidly, the figures will remain constant for plates added subsequently, but where this is not the case (as in Fig. 3, Plate 5), subsequent introduction of plates will contaminate the water to such an extent that it may be impossible to reach the limiting concentration in any reasonable time.

Summary.

A suggestion is put forward for calculating the quantity of residual hypo permissible in a photographic plate.

Washing devices are compared with respect to their water-changing properties, and are further tested practically.

The conditions underlying the rapid washing of plates are investigated qualitatively by means of a coloured dye.

A preliminary figure is given, correlating these results with those for the washing of plates containing hypo.

Recommendations are made for the production of an efficient washing device.

Note on a Rocking Machine used in these Experiments.

In the diagram, Fig. 3, Plate 6, A is a flexible diaphragm in connection with a water supply pipe W, and a siphon outflow C. An air inlet tube D joins C at *b*. Water entering by W swells A, developing pressure as it mounts C. When it reaches the head it flows down the other side, the pressure in A falls to zero, and air is sucked in through D, thus breaking the siphon. The cycle then repeats itself. This changing pressure on the diaphragm A causes it to rise and fall; and this motion has been used to operate the rocker shown in plan in Fig. 4. Here two expanding rubber bladders and a universal joint form a three-point support for the rocking table T. The water supply passes through two miniature filter-pumps P, and inflates the bladders with air and liquid. These separate into two layers, affording the means of sealing and breaking the siphons, as well as economising in water. The bladders work out of phase, and, owing to their elasticity, with continually changing amplitude, rocking a dish placed on the table in every direction. The absence of a definite cycle avoids the production of streak marks on the plates being rocked. It may be remarked that a rocker built on these lines, and with bladders 3 inch diameter, in series with 24 inch siphons, has been in

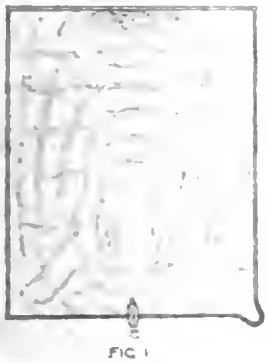

FIG 1

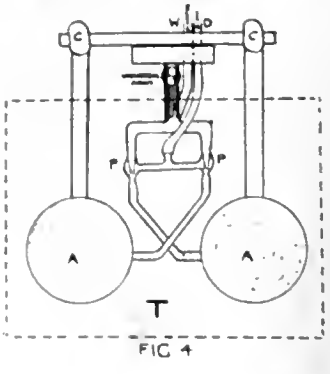

FIG 4

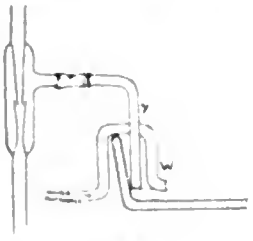

FIG 2

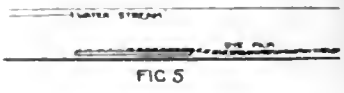

FIG 5

FIG 6

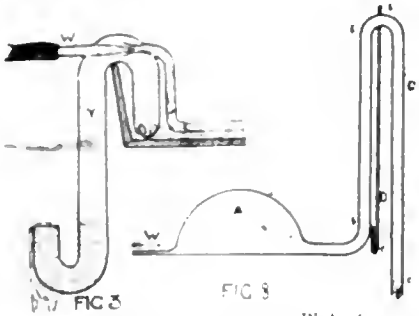

FIG 3

FIG 8

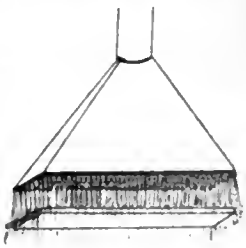

FIG 7

continual use for some months without attention. It will agitate a 12 inch by 10 inch porcelain dish with normal contents.

In conclusion, our thanks are due to Professor H. B. Baker for the generous facilities placed at our disposal, and to Mr. H. J. T. Ellingham for the valuable interest he has shown throughout.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

A Use for Spool Bobbins.

THE accumulations of empty spool bobbins, which occur in D. and P. rooms, often give rise to the question, "Cannot anything useful be done with them?" or the remark, "What a pity to waste all those." While not pretending to have found a use for the masses of bobbins which collect every season, I have found an occasional use for odd ones, for a purpose for which they are eminently suited.

They make very efficient wall plugs. Most photographers at some time or other have need to put up a new fixture, or repair an old one, and these jobs are never so awkward as when support is taken from a brick wall. The time-honoured method of smashing a hole in the wall with a cold chisel, and plugging it with a lump of wood, is neither pleasant to do, nor nice to look upon. With the aid of an old bobbin the matter is greatly simplified. All that is necessary is to make a deep hole between two bricks, with a six-inch nail and a hammer, and to remove the metal cap from the split end of the bobbin. This end then needs shaving down a trifle. The nail must be driven into the wall as cleanly as possible, and removed without enlarging the surface end of the hole any more than can be helped. If a selection of different sized bobbins is at hand a length can be chosen according to the depth of the hole, which, in its turn, should depend on the weight of the fixture. This is naturally a matter of guesswork raher than precision, but a couple of No. 1 Brownie bobbins will hold at least ten or twelve pounds, and two 3-A's will hold very much more. Having removed the nail, the bobbin is hammered in by blows on the metal end. There is no risk of splitting the wood, and when the cap is flush with the wall, it hides any unsightliness due to loosened mortar. The hole for screw or nail is already in position, and again splitting is avoided, and a long screw can be used with advantage. Small bracket shelves can be fitted to the workshop wall in a minimum of time in this way. It is also possible to construct a set of shelves by securing further pieces of shelving to the first by sets of four equal sized bobbins without caps removed, screwed leg fashion at the corners of the shelves. If the series is carried any height, however, it will be advisable to fix both top and bottom shelves to the wall.—THERMIT.

Timing in the Dark Room.

A USEFUL piece of apparatus to have in the dark-room is a metronome, an instrument used by those whose business it is to teach the young the meaning of time and rhythm in music.

For timing the exposure of bromide paper up to 60 seconds, if set to beat once to the second, it relieves the printer of all necessity to take his eyes from the work, a very great help when a particular piece of shading has to be performed.

For example, suppose that a number of enlargements are wanted where, say, the foreground has to receive 10 seconds' extra, and a sky printed in from another negative which requires 3 seconds.

The steady ticks of the metronome, so easy to count, enable one to expose a succession of sheets of paper with absolute uniformity, leaving at the same time the hands free, and also enabling the eyes to be kept on the shading, which, unless this is done, is liable to stray behind its proper limits with unpleasant results. A metronome may frequently be purchased secondhand for about 10s., the price new is 20s. to 25s.—E. S. TARDREW.

THE 1923 NORTHERN EXHIBITION.—The Northern photographic exhibition will be held in the Manchester City Art Gallery during February, 1923. The management have decided to make admittance free to the public, and are leaving no stone unturned to maintain the best traditions of the Northern when previously held in Manchester. Full particulars will be announced shortly, but meanwhile the organisers, a moving spirit among whom is Mr. S. L. Coulthurst, take this first opportunity of asking for the support of exhibitors throughout the world. They desire to point out that every picture will be submitted to the judges before any hanging is done, and that the judges will be required to mark each submitted exhibit A, B, or C, these markings respectively denoting: A, must be hung: B, may be hung if space, etc., permits, and C, must not be hung.

Photo-Mechanical Notes.

Stencils by Photographic Methods.

PHOTOGRAPHIC methods of making the stencils used in letter-copying and manifolding machines are the subjects of two recent patent specifications. According to No. 179,593, granted to Louis Sterck and Roneo, Ltd., a photographic negative is produced on either a wet plate or a dry plate, the object appearing thereon either of the same size as the original, or a reduction or an enlargement thereof as required. From the negative a positive is obtained, either through the camera or by contact, and a screen may be used in obtaining the negative or the positive plate according to the nature of the original to be reproduced by the photo metal stencil.

A polished sheet of brass, copper, zinc, or other metal is next coated with a suitable sensitiser such as albumen, bitumen, or enamel, and a negative copy is made to appear upon the metal sheet by exposing it to the light through the positive plate in a printing frame. After the necessary amount of exposure has been given, the sensitised metal negative is developed according to the particular sensitiser used.

In the event of some retouching of the negative metal plate being required, this can be effected with any acid-proof substance.

The metal negative is now ready for etching, and the print or design shows quite clean, and is free from any acid-proof substance. The metal negative is now placed in an acid bath, and the etching process is continued until the copy appearing on the metal is etched right through the metal.

As, however, it often happens that the metal is not of even thickness, some parts of the metal will be etched through quicker than the remaining parts. When this occurs, the metal plate should be removed from the bath, washed and dried, and further action of the acid on the etched-through part prevented by applying a suitable anti-acid coating thereto.

The metal plate is again placed in the acid bath, and is then washed and dried, and, if desired, deprived of the adhering substance by means of pumice stone, and now appears as a photo-metal stencil ready for use with a rotary duplicating machine or a flat frame duplicator.

In the event of the stencil being too thin, an absorbent strengthening material such as flannelette, felt, velvet or the like is applied thereto.

Reference has been directed by the Comptroller of Patents, in pursuance of Section 7, Sub-section 4, of the Patents and Designs Acts, 1907 and 1919, to Specifications No. 5,402 of 1896, No. 10,073 of 1899, No. 14,374 of 1899, and No. 3,988 of 1911.

According to Specification No. 178.884, of David Gestetner, Neo-Cyclostyle Works, Tottenham Hale, London, N.17, the stencil layer is produced by causing a silver image formed by the action of light upon a sensitive silver salt to interact chemically with a composition, as, for instance, bichromated gelatine, in order to change the solubility of the composition in a medium used as a developer.

The invention in one phase comprises producing a print by the action of light upon a silver compound, such, for instance, as is employed in coating bromide paper, and bringing together the print and a pellicle (of a composition adapted by the chemical action of the silver image on the colloid to change in respect of its solubility) in a developing medium, under conditions to effect such change, and developing the pellicle.

The pellicle may be coated on a temporary support or on a final support of a porous character, as, for instance, Yoshino paper, in which latter case it may be desirable to bring the back of the coated support into contact with the silver print.

Alternatively, the material adapted to act as the final support of a porous character may be coated or treated with a composition containing a suitable sensitive silver compound, and after producing thereon a silver print, a pellicle of a suitable composition, as, for instance, bichromated gelatine, may be applied, in conditions adapted to effect the desired change in the solubility of the composition.

The silver print in either case may be treated in a manner similar to that followed in the Ozobrome (Carbro) process, with a solution of bichromate, fericyanide, and bromide of potassium.

Another phase of the invention comprises producing by photographic means a silver image on a layer of an emulsion of a sensitive silver salt in a composition the solubility of which, in a medium, as, for instance, warm water if the composition is bichromated gelatine or gum used subsequently as a developer, is adapted

to be changed in accordance with the intensity of light-action on the layer, treating the layer to effect the desired change in solubilty and developing the treated layer.

The layer of emulsion may be constituted by a gelatine emulsion resembling the emulsion used in making bromide paper, but preferably not hardened, and the support coated with this emulsion may be exposed, treated in the usual way to produce a silver print, treated, if necessary, to change the solubility of the gelatine in the medium subsequently used as a developer, and finally developed, as has previously been proposed in the production of "pigment" or "carbon" prints.

Alternatively, a support, similarly coated, after exposure and development of the silver image, may be sensitised by means of a suitable agent, as, for instance, a bichromate exposed to the action of light and redeveloped to remove those portions of the gelatine layer which have been less affected by the action of light as the result of the silver image preventing or reducing the action of light upon the sensitising agent.

The gelatine emulsion containing the light-sensitive silver salt in this phase of the invention may be supported on a porous material, as, for instance, Yoshimo paper, adapted to act as the final support.

Alternatively, the gelatine emulsion containing the sensitive silver salt may be coated on a support from which it may be stripped and transferred to a suitable final support for use as a stencil.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications June 19 to 24 :—

APPARATUS.—No 17,107 Photographic apparatus. W. A. Lawton.

APPARATUS.—No. 17,063. Photographic apparatus. W. Feuerzeug.

LENSES.—Nos. 16,902 and 16,903. Photographic objectives. C Graf.

ELECTRICAL PHOTOGRAPHY.—No. 17,227. Electrical photography. D. Charles.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country or abroad, in the case of patents granted under the International Convention.

PHOTOGRAPHS WITH SPECIAL BACKGROUND EFFECTS.—No. 175,020 (January 28, 1921). This invention relates to means for taking photographs with special scenic or background effects, and its object is to provide means whereby a background of any size or proportion in relation to the size of the objects or figures to appear in front of the background, can be photographed at the same time as the objects or figures by one exposure, the resultant effect being that the figures or objects appear in proportion to the view forming the background.

A further object is to provide improved means for taking either stationary or moving pictures whereby in one exposure a background or the like and figures, objects or the like, can be photographed to provide a natural or grotesque picture, the background and figures or objects being of different proportionate sizes in relation to each other and arranged at different angular positions with respect to the camera employed for taking the picture.

A further object is so to arrange the background that during the taking of the photograph of the figures or objects and the background, the latter will be away from its normal position so that the figures can be illuminated to a greater degree than the background, or *vice versa*, thus enabling certain parts of the resultant picture to appear particularly prominent.

A further object is so to arrange the background that the objects, figures or the like which are being photographed in connection therewith can during the taking of a moving picture appear to vanish or pass away to provide an illusion effect, while a further object is so to arrange the background that it may be a picture, painting or view of any size or colour or a screen upon which cinematograph pictures are adapted to be projected.

The invention consists in providing a portable device for attachment to, or use in connection with, cameras for taking photographs with special scenic or background effects comprising

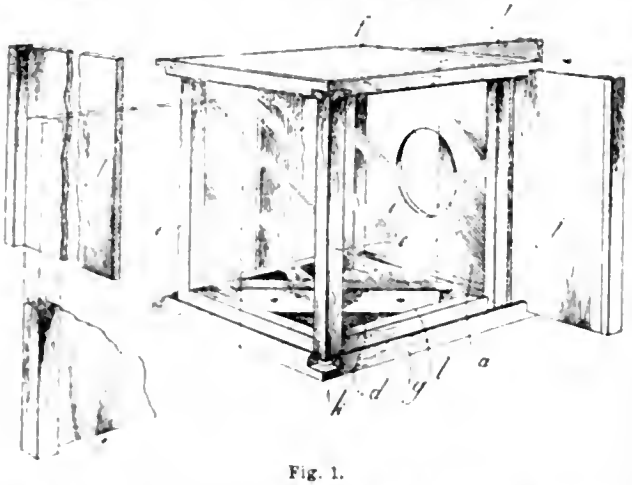

Fig. 1.

a frame work or support and a transparent screen arranged in connection therewith at an angle of substantially 45 degrees to the plane of the lens of the camera, so that the photographing of a background and objects, figures or the like can be performed in one exposure. For instance, a background in the nature of a stationary or moving picture, painting or the like may be arranged

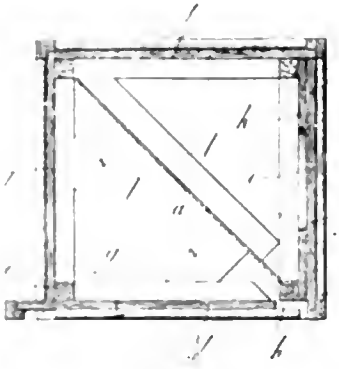

Fig. 2.

to one side of the camera and the objects, figures, etc., to be photographed may be arranged in front of the said camera.

Fig. 1 is a perspective view of one form of cabinet for use in conjunction with a camera. Fig. 2 is a sectional plan thereof, and figs. 3 and 3 are diagrams of the means employed for taking photographs.

According to one form of this invention a screen of suitable

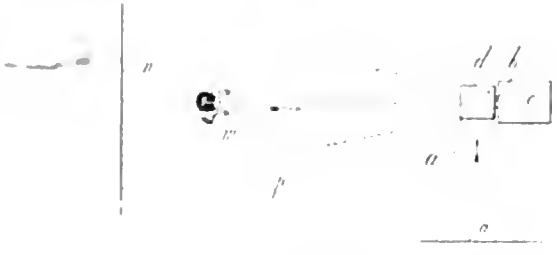

Fig. 3.

transparent material *a*, such, for instance, as sheet or plate glass, is arranged at an angle of 45 degrees in front and adjacent to the lens *b* of a camera *c* it is desired to employ to photograph figures or objects placed in front thereof. This transparent screen *a* is preferably mounted in a suitable frame cabinet *d*, which comprises a skeleton framework *e* fitted with a top *f* and bottom *g*.

One side *h* of the cabinet *d*, which is adapted to be placed adjacent to the camera *c* may be enclosed, and in such cases it is provided with an aperture *i* of suitable size to permit the photograph to be taken by the lens *b* of the camera *c*. In use two sides of the cabinet *d* are normally open, but in the construction shown they are adapted to be closed or partially closed by sliding panels *j* mounted in suitable grooves *k* formed in the top and bottom covers *f* and *g* of the cabinet *d*. The top and bottom of the glass screen *a* is preferably supported by suitable members *l* secured to the top and bottom of the cabinet. In front of the cabinet *d* and camera *c* which latter is disposed a short distance to the rear of the cabinet *d*, is arranged the object or figures indicated at *m* which it is desired to photograph. These objects *m* are arranged at any suitable distance from the camera *c* and in front of a background screen *n* of opaque material, such as a black or dark-coloured screen. The floor upon which the objects are arranged is also of dark material. Means not shown are provided preferably at the side of and in front of the screen *n* to illuminate the objects or figures *m* in any desired degree. The illuminating means are preferably so arranged that the light will not fall upon the darkened screen to the rear of the objects or figures. To one side of the cabinet *d* is arranged a background *o* which may be in the nature of a picture or painting of any colour or size, or it may be in the nature of a moving picture. In this

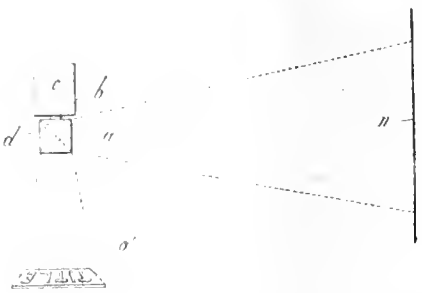

Fig. 4.

latter arrangement the background screen *o* is preferably transparent, so that moving pictures from a suitable cinematograph apparatus arranged at the rear thereof may be projected thereon. The picture which is adapted to constitute the background is suitably illuminated so that its reflection will be conveyed to the angularly arranged screen *a* of the cabinet *d*. Thus when a photograph is taken by the camera *c* a reproduction of the background *o* reflected on the screen and the objects *m* in front of the screen *n* will be produced on the plate or the like in the camera. It will thus be seen that a background *o* can be of small size in proportion to the figures *m* to be photographed. Upon one exposure of the plate a picture will be reproduced of the figures, together with the background. The camera employed may be an ordinary camera or one especially adaptable for taking cinematograph photographs. In the latter cases the background *o* may be movable or the objects or actors may be arranged to move in front of the darkened background *n*. It will be understood that the cabinet *d* and/or the transparent screen may be provided with means whereby either or both may be adjusted in relation to each other as desired.

In order to take imaginative pictures, places or, for instance, visions or apparitions, a suitable opaque and darkened screen indicated at *p* in fig. 3 is arranged in front of the main darkened screen *n* and to one side of, for instance, a figure indicated at *m* being photographed. When it is desired to cause the figure to vanish during the taking of the photographs, the figure moves or is caused to move to one side behind this auxiliary darkened screen *p*. Thus when the photographs taken by the camera are reproduced a very natural vanishing effect will be apparent. It will be understood that apparatus may be employed to take photographs of various composite pictures and figures in a simple manner and by one exposure for each photograph, and be equally efficient for producing ordinary photographs on various forms of background or for cinematography.

If desired, other effects may be arranged in front of the camera to combine with the background when the photographs are taken. For instance, as shown in fig. 4, the cinematograph camera *c* and the cabinet *d* are arranged in a vertical position to photograph a title *o'* disposed on the floor and a scenic effect arranged on the screen *n*.

It will thus be seen that, for instance, people may be photographed together with backgrounds which are of reduced size and proportion, but by the above-described means the resultant picture is such that this relative difference in proportion is rectified to provide natural pictures or varied to produce grotesque pictures. If desired, the panels may be in the form of or provided with vignetting screens.

In cases where the background or picture to be reflected is too small to come within the range of the focus used on the figures, after necessary stopping down, a lens or magnifying glass may be arranged between the reflector and the picture. The magnifying glass, when such is employed, is preferably arranged in one side of the cabinet. The focus of the picture is preferably adjusted to the focus of the camera.

In a modified construction the transparent screen is angularly arranged inside a camera having a lens in front and at one side, so that pictures may be taken on a negative arranged at the back of the transparent screen of objects and backgrounds disposed in front and at the side of the camera.—Godfrey Heathcote Sutcliffe, 57, Argyle Road, West Ealing.

Trade Names and Marks.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register :—

KODAK TESTED CHEMICALS (DESIGN).—No. 421,047. Photographic chemicals. Kodak, Ltd., Kodak House, Kingsway, London, W.C.2, dealers in photographic materials.

APEM.—No. 419,775. All goods included in class 1. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1, manufacturers.

APEM.—No. 419,776. All goods included in class 8. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1, manufacturers.

APEM.—No. 419,777. All goods included in class 13, but not including needles or fastenings for collars, and not including any goods of a like kind to these excluded goods. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1, manufacturers.

APEM.—No. 419,778. All goods included in class 39. Amalgamated Photographic Manufacturers, Ltd., 3, Soho Square, London, W.1, manufacturers.

South Suburban Phot. Soc. Outing—St. Albans.
Wallasey Amateur Phot. Soc. Outing—Runcorn and Widnes.

CROYDON CAMERA CLUB.

Mr. F. Ackroyd lectured on "Internal Combustion Engines," and scored heavily for the informal session, which many infinitely prefer to the orthodox photographic side. In the clearest possible way he sketched the history, and then turned in detail to the various functions of petrol and other internal combustion engines.

The start would certainly have embarrassed other than a Croydonian, for a chance observation threw Mr. Rose into reminiscent vein. Interposing, after a long preamble, he gently murmured, and completely murdered a good tale next on the list in the lecturer's notes. Then Mr. Salt's recollections on the "Otto cycle" necessitated some discursive observations, and drew from the patient Mr. Ackroyd a remark that a few more interruptions of the same sort would practically exhaust in advance the lecture he proposed to give. "Have I your kind permission, gentlemen, to continue it," he humbly asked, and, receiving a gracious assent, resumed his discourse without further outside aid.

The evening concluded with the ignition of petrol and other fluids employed. Prior to the war, he said, if the petrol gave out it was possible to run home on a bottle of whisky. A test then made with the club's up-to-date brand proved its efficacy in a contrary direction. As a fire extinguisher nothing better could be desired.

Commercial & Legal Intelligence.

Legal Notices.—Notice is given that a general meeting of the members of Photo Productions, Ltd (in voluntary liquidation), will be held on August 3, at 3 p.m. at 1, Eton Terrace, Richmond, Surrey, for the purpose of considering the liquidator's report, showing the manner in which the winding-up has been conducted, and the property of the company disposed of.

Equitable Assignees of Copyright.—In the Court of Appeal last week judgment was delivered by Lord Justice Bankes, Lord Justice Aitken, and Lord Justice Younger in the case of the Performing Rights Society Ltd., v. London Theatre of Varieties, Ltd. Although the action did not relate to works of graphic art such as photographs, the judgment has a far-reaching effect in respect to the remedy for the infringement of copyright acquired by assignment under certain conditions, and from this standpoint is the subject of an article on another page.

The following abridged text of the judgment is quoted from the "Times":—

Lord Justice Bankes, in the course of his judgment, said:—This appeal raises two questions of considerable importance, the one in relation to the law of copyright, the other in relation to the law governing trade unions. The action was brought by the respondents, a company registered and incorporated under the Companies Act, claiming an injunction to restrain the appellants from infringing their copyright in the right to perform in public musical works in which the right of performance was in the respondents. The two main grounds of the defence to the action were (1) that the respondents were a trade union within the meaning of the Trade Union Acts, 1871 to 1913, and as such their registration and incorporation as a company were void and unlawful; (2) that the respondents were not the owners of the copyright which they claimed, so as to maintain the action in their own name. The first question presents little difficulty. Mr Justice Branson decided it in favour of the respondents. In my opinion he was right.

The point with reference to the right of the plaintiffs to sue in their own name raises a serious and important question of copyright law. It arises in the following circumstances. In the case of the song "A Devonshire Wedding" the plaintiffs had, on June 26, 1916, taken an assignment from Messrs. Chappell & Co., Ltd., of the right of performance in all parts of the world of each and every song, with the words thereof, or musical work, not being a musical play, the right of performance of which then belonged to, or should thereafter be acquired by, or be or become vested in them, during the continuance of Messrs. Chappell's membership of the plaintiff society. The song in question was not then composed, and it was not until January 3, 1919, that the composer assigned the right of performance to Messrs. Chappell. The plaintiffs' claim to the copyright in the second song referred to in the pleadings was founded on a similar title derived from Messrs. Keith, Prowse & Co.

The plaintiffs did not dispute that, in these circumstances, their only claim to the copyright in the two songs was as equitable assignees from Messrs. Chappell and Messrs. Keith, Prowse & Co. The defendants contended that an equitable assignee of copyright could not sue in his own name for infringement, but must do so either in the name of the owner at law, or must make the owner at law a party to the action, in order that he might be bound by any judgment obtained. Having regard to the equitable rule as to priorities between the equitable and the legal owner of property without notice, I think that the defendants' point must be well founded, unless there is some provision in the Copyright Act which justifies a decision in the plaintiffs' favour. If it were not so a person might be liable to be sued for infringement both by the legal and by the equitable owner of the copyright, and that in spite of the fact that in each action he might have a complete defence against the owner other than the one by whom he was at the moment being sued. In spite of the inconvenience of holding that a mere equitable owner of copyright cannot sue for infringement in his own name I am not prepared to hold that he can, unless the statute in clear language gives him that right.

The Copyright Act, 1911.

The Copyright Act, 1911, is the statute to which reference has to be made. Section 5 is the section which deals with the ownership of copyright. It defines who the first owner of copyright of a work shall be. It confers upon the owner of the copyright in any work the right to assign the right or to grant any interest in the right by licence provided that the assignment or grant is in writing signed by the owner. It is the owner of the copyright who is entitled to all civil remedies for infringement (section 6), and no person is entitled to copyright or any similar right in any literary, dramatic, musical, or artistic work, whether published or unpublished, otherwise than in accordance with the provisions of the Act (section 31).

The effect of this legislation is to render it possible that there should be within the meaning of the statute two owners of the copyright in any work at one and the same time. In the case where the copyright is, so to speak, split, section 5, subsection (3) recognises both the assignee and the assignor as owners of their respective rights. Under the proviso to subsection (2) of section 5 the legal personal representatives of an author who was the first owner of copyright in his work are the owners of the reversionary interest in the copyright expectant on the termination of the period indicated in the Act. I can see nothing in the statute from which I can draw the inference that an owner of copyright, whether the first owner or any subsequent owner by legal assignment, ceases to be an owner within the meaning of the statute when he executes an equitable assignment of the whole or part of his right. If this is so, it follows either (*a*) that the equitable assignee is not an owner at all within the meaning of the statute, or (*b*) that the statute recognises in these circumstances two owners, the legal and the equitable, of the one right. Whichever view is correct it appears to me that, apart from authority, the result in this action is the same, namely, that the plaintiffs should not be allowed to maintain the present action without adding the legal owners of the copyright.

If the first conclusion is the correct one, then the action cannot proceed without them. If the second is correct, then the Court, in the exercise of its discretion, should not allow the action to proceed in the absence of a party who may be interested and who ought to be bound, or whose presence might afford a defence to the defendants. There are difficulties in the way of accepting either conclusion, but the difficulty of accepting the second appears to me to be less than that of accepting the first. If the first is accepted the logical conclusion appears to be that no equitable assignee of copyright can ever maintain a claim for infringement either in a Court of law or equity, because the Act of Parliament only recognises the owner as the person who can claim the assistance of the Courts, and on this assumption the equitable assignee is not the owner and can never become the owner, unless and until it either becomes possible for the owner to make a legal assign-

ment of the right or he can be persuaded or compelled by process of law to make such an assignment.

I do not think that the language of the statute justifies such a conclusion, and I prefer a construction which includes the equitable owner in the expression owner, and then leaves it to the ordinary practice of the Courts to secure all proper parties being before the Court. I think that this view is in accordance with the practice as it existed before the Judicature Act, and before the passing of the Copyright Act, 1911.

After referring to the authorities, his Lordship said :—For the reasons I have given, I am unable to agree with the view taken by Mr. Justice Branson on this part of the case, and I think that he should have given effect to the defendants' objection to want of parties, but on proper terms should have acceded to the plaintiffs' application to join the legal owners of the copyright.

With reference to Mr. Maugham's argument on this part of the case, founded on the provision of Order XVI., Rule 11, that an action is not to be defeated by reason of the non-joinder of parties, I would only observe that the Court gives effect to that rule, not by ignoring parties, but by adding them where necessary, and that where the presence of a party appears to be necessary it is not sufficient to urge in his absence that he is a bare trustee for the person who is bringing the action.

I think that the appeal must be allowed, with costs, but the respondents must have an opportunity of amending by adding the legal owners of the copyright as parties, but only upon the terms offered them in the Court below—namely, on paying all costs thrown away, in any event. If the respondents elect within ten days to amend on these terms, then the order of this Court will be an order setting aside the judgment, and directing a new trial upon the terms of the respondents paying all costs of and caused by the amendment, and all costs thrown away, including the costs of the appeal, in any event; any costs of the first trial not included in the above order to abide the event of the new trial. If the respondents elect not to amend then the judgment is set aside, and entered for the appellants, with costs here and below.

Lord Justice Aitkin and Lord Jusice Younger agreed.

NEW COMPANIES.

K. D. Photographic Inventions, Ltd.—This private company was registered on June 23 with a capital of £7,500, in 7,000 shares of £1 each and 10,000 ordinary shares of 1s. each. Objects : To acquire and deal in any patents, etc., conferring an exclusive or non-exclusive or limited right to manufacture and sell photographic apparatus and chemical fluids and the like, and to carry on the business of photographers, producers of pictorial photography, manufacturers of and dealers in cameras and other photographic and film-producing apparatus, etc. The subscribers (each with one share) are :—R. W. Bolton, 140, Rosebery Avenue, Manor Park, Essex, managing clerk; Daisy Philipps, 54, Wiltshire Road, Brixton, S.W.9, shorthand typist. The subscribers are to appoint the first directors. Secretary : R. W. Bolton. Registered office : 87, Moorgate, E.C.

Wellington and Ward, Ltd., was registered as a private company of June 27, with a nominal capital of £200,000, in 50,000 10 per cent. cumulative preference and 150,000 ordinary shares of £1 each. The objects are : To acquire the business carried on at Elstree, Herts, and elsewhere, as Wellington and Ward; to adopt agreements (1) with J. B. B. Wellington, H. W. Hall, and H. H. Ward (vendors); (2) with J. B. B. Wellington; (3) with H. W. Hall; (4) with H. H. Ward; and (5) with C. S. Downing; and to carry on the business of manufacturers of photographic plates, papers, films and chemicals, photographic apparatus and materials, etc. The directors are:—J. B. B. Wellington, The Leys, Elstree, Herts; H. W. Hall (chairman and managing director), Bennington Park, Stevenage, Herts; H. H. Ward, Warfield, Radlett, Herts; C. S. Downing, Whitemead, Mill Hill (joint managing director). Qualification : £250. Remuneration of managing directors as fixed by the board. Secretary: C. S. Downing. The registered office is at Shenley Road, Elstree, Herts.

In a circular letter to the trade Messrs. Wellington and Ward inform their customers that they have registered their firm as a private company for personal reasons. Moreover, the change is the outcome of the steady growth of the business, the control and further expansion of which will be facilitated by its incorporation. There will be no change in the policy, and the direction of the business will remain as in the past. Mr. H. W. Hall will be Chairman of the Board and Managing Director. Mr. J. B. B. Wellington, as Director on the scientific side, will fully maintain his connection with the business, and Mr. H. H. Ward will continue his present functions as Engineering Director. Mr. C. S. Downing, for many years Manager of the firm, appropriately becomes joint Managing Director.

News and Notes.

Mr. H. H. Featherstone, F.R.P.S., who for the past thirteen years has been instructor in photography in the Catford Commercial Institute, has been appointed assistant editor of the "British Journal of Photography." Mr. Featherstone will take up his duties early in September next.

Dublin Photographs.—One of the first to visit the Four Courts after their surrender was Mr. G. Limbrey, of the Photo Press Agency, who secured a number of the photographs which have been reproduced in the Press. In the "Weekly Dispatch" of last Sunday, July 2, Mr. Limbrey gives a description of the typically Irish scenes of the surrender, and of his rapid retirement from an unexploded bomb.

Summer Snapshots.—The "Westminster Gazette" invites its readers to send in photographs containing as much news value and human interest as possible, and a prize of one guinea will be given every Tuesday and Friday (to September 29) for what is regarded as the best photograph on these days each week. In addition, the Editor reserves to himself the right to use any photograph on any day, and will pay a fee of 10s. 6d. for each one used. At the end of the season a prize of a handsome Kodak camera and materials to the value of 20 guineas, to be selected by the prize-winner, will be awarded to the competitor who has, in the opinion of the Editor, sent in the three best pictures. All photographs should be addressed to the Photo. Editor, "Westminster Gazette," 104, Shoe Lane, E.C.4, and should be carefully packed.

British Photo-Base Paper.—At the annual general meeting of Wiggins, Teape & Co. (1919), Ltd., held on June 29 last, the Chairman, Mr. P. W. Holden, referred to the progress made by the company in the manufacture of photographic base paper. It was a new trade for this country—a highly technical and scientific trade, and one which had many sides to it. They had now got a mill in all essential features admirably suitable for the manufacture of this paper. Some grades that they were making were giving complete satisfaction to their customers—grades which they could not make at the old mill, and which formerly came from abroad. Other grades had yet to be improved, but the company had running orders in hand which they were able to execute at a profit, and he could speak hopefully of the prospects of this branch. Shareholders would realise that the photographic trade had suffered, like most other trades, from the general depression —especially the professional trade—but, on the other hand, he believed that photography as applied to advertising was only in its infancy. Much of their base was used for that purpose, and he had great faith in the future.

Irish Salon of Photography.—We hope that events in Ireland will allow of the holding, as is proposed, of the First Irish Salon of Photography, in the Metropolitan School of Art, Dublin, from August 14 to 25, this year. The salon will comprise three classes : the first, A, open to residents in Ireland and Irish photographers overseas; the second, B, open to all amateurs and professionals at home and abroad; and the third, C, open to professional photographers resident in Ireland. Classes A and B are divided into seven sections : (1) Landscape, seascape, genre, architecture; (2) Portraits and figure studies; (3) Nature pictures; (4) Scientific and technical; (5) Monochrome slides; (6) Colour photography; and (7) High speed photography. An award of a silver cup or shield is offered in Classes A and B, and in each of the seven sections one award only will be made of a gold, silver, or bronze medal at the discretion of the judges. The entry fee is 5s., with an additional fee of 2s. 6d. for each print above six. The judges are Mr. Alfred Werner, F.R.P.S., Dr. Dermod O'Brien (President Royal Hibernian Academy), and Mr. J. A. C. Ruthven (Past President, Photo-

graphic Society of Ireland). Further particulars of the Exhibition and entry forms may be obtained from the Honorary Secretary, Mr. William Harding, Irish Salon of Photography, Metropolitan School of Art, Kildare Street, Dublin.

VIEW-POSTCARDS.

To the Editors.

Gentlemen,—In the article on the above subject in your issue of June 23 last the writer is somewhat sanguine as to the possibilities of this work for the small professional photographer.

I venture to say that too much should not be expected from this source, and that in fact it would be very easy to come out of such an enterprise with a loss. I have made some experiments in this direction in my town and in the surrounding districts, and had I not been extremely cautious I should most assuredly have lost money.

Among other things I found that the best pictures, i.e., those which made the best compositions were not good sellers, the public, I was told by the retailers, liked a well-known view, and a commonplace one at that, far better than a composition which they would admit readily was very "nice" but did not buy.

Then I set out *to* give them the "usual thing": these went fairly well at first: then I was up against the big firms.

These firms are really the great trouble and it is almost hopeless to attempt to compete against them as apart from ordinary competition they appear to periodically unload surplus stocks on the retailers at ridiculous prices. This they can do with their large selling organisations in one day over a large district and the unfortunate photographer will find his customers loaded up with stuff that they have been tempted to buy at a cheap price.

The result is that where one has every reason to expect orders for several gross, only a few are ordered, and in some cases none at all, which means that the time spent on calling is frequently not paid for. This is the fact which I know from personal experience, and although I have not given up the work entirely, I do but very little and only when I am sure of placing the results.

You will, I am sure, not object to my sending this little résumé of my experiences, and perhaps you will agree with me that a word of caution is due to those of your readers who may be inclined to risk capital *on* a branch of protography which is now unfortunately in the hands of capitalists.

Mr. Denton does, in his article, advocate leaving the town alone, but suggests that in smaller centres there is scope, and mentions the case of a man, who could not get supplies of a particular view without difficulty. That man I have met and taken endless trouble to get what he required, usually from an impossible position where the light was always difficult, when done perhaps he will give you an order for three dozen.

No, those who look to postcard work on a small scale for a profitable outlet for their energies will, I am agraid, be disappointed.—

Yours faithfully,
E. S. TARBREW.

Lansdowne Road,
Croydon,
June, 28.

PHOTOGRAPHIC BUSINESS IN JAPAN.

To the Editors.

Gentlemen,—We have read with interest the letter in your issue of June 30, by "Britisher," headed "Photographic Business in Japan," and we think the thanks of the photographic trade are due to this gentleman for his letter.

It is quite true that since 1919 there has been a very steady increase in imports of British photographic apparatus to Japan, and we ourselves have, during the last two or three years, shipped to that country considerable quantities of cameras, particularly of the higher class. There is little doubt that during the past twelve months the Germans are once more securing a strong foothold with their cameras and lenses which we think is due entirely to the depreciation of their currency and the consequent low prices at which they are able to sell their goods, and our sales have fallen off considerably.

With regard to the Tokyo Peace Exhibition we ourselves have sent out a fine exhibition of our goods to one of the leading wholesale houses in Tokyo, and this house is exhibiting it on our behalf.

As regards sending goods to the various "direct importers," we quite agree with "Britisher" that it is a very dangerous thing to do unless the orders are accompanied by a confirmed letter of credit against which cash can be drawn from one of the London banks, and we would strongly advise anyone shipping to Japan except to the wholesale houses who are well known to them, to refuse any orders that are not accompanied by such letters of credit.

We have one case in mind of a firm who wrote to us sending small orders, giving us references to the leading manufacturers over here, and stating that they were getting goods from them on the terms of thirty days' sight documents on payment. This firm sent us three or four small orders which we executed on these terms, and the drafts were duly honoured and the goods taken delivery of. They then sent us a further larger order, which we executed on the same terms—namely, thirty days' sight documents on payment. On arrival of the goods the draft was not paid, but, fortunately, as we had consigned them to one of the banks in Japan, the customer was unable to get delivery of the goods. Nevertheless, we have all the attendant expenses incurred for duty, bank charges, etc., besides which there are the expenses of freight out and home on the goods.

We certainly agree with "Britisher" in his remarks that unless the importers are well known to suppliers, goods should only be sent when orders are accompanied by the letter of credit as mentioned above.—Yours faithfully,

HOUGHTONS, LTD.,
F. M. ISAACS,
Director.

High Holborn, London, W.C.2.
June 30

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—Replying to Mr. Sukamar Ray's letter, I have carefully re-read the extract referred to by me on April 28, and I am unable to agree that I have misread it. There is not a word about the screen distance being below the normal, although the diagram suggests that it is so. The author distinctly states that "In the great majority of cases we actually increase the nucleus of the dot by reducing the size of the stop," and the footnote explains that the exceptions are cases where large stops are used with a screen distance *greater* than the normal, and where small stops are used and diffraction effects are prominent.

I stated that I did not agree with Mr. Ray's conclusions for the reason that I cannot find anything in practice that agrees with the geometrical projection used by him. On page 36 of the same article the author says "the gradation with a single stop is very feeble." His conclusions in this respect are explained by the missing factor in the normal equation, the screen distances being always too great for the stops used.

I am sorry to appear to criticise Mr. Ray's work of twenty-five years or so ago which was, and is, of the greatest possible value, and all I can hope to do is to supplement it and make it more complete.

With regard to obtaining similar gradation with coarse and fine rulings, this must not be taken in a strictly literal sense, as it is quite obvious that a coarse screen must have a longer contrast scale than a fine screen owing to the greater distance between the dot centres. Such gradation can be obtained as the copy or class of printing demands, the contrast scale being strictly under control and with one stop

I agree with Mr. S. Ray as to the advantage of some simple method of measuring the total scale of an original, and I believe that an instrument has been worked out by Mr. C. H. Sharp, but I have no personal knowledge of it. At the present time our copies are graded into five classes judged by experience only as to tone scale and colour and, although this method leaves chances for error, it works out very well in practice.—Yours faithfully,

E. A. Bierman, F.R.P.S.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

H. C.—Three-ply wood of about 3/16ths thickness is used for statuette photographs. For small quantities go to Messrs. Hobbies, Ltd., East Dereham, Norfolk, or their agents in Blackpool, Messrs. the Blackpool Cycle Co., 193, Church Street, Blackpool. An article, giving full instructions, appeared in the "B.J.," October 10, 1913, obtainable from our publishers, price 5d., post free. Messrs. Campbell Gray, Ltd., 88, Edgware Road, London, W., make these statuettes from photographers' negatives.

G. F. D.—We have referred your query of June 27 to Mr. Ermen, who replies as follows:—The Monomet caustic developer should not be discoloured when it is made, even if the Monomet itself is somewhat old or discoloured, unless it contains an excess of caustic soda or a deficiency of sulphite, due to the use of inferior metabisulphite. Metol may be used instead of an equal weight of Monomet, but the preparation is more difficult, owing to the low melting point of the metol base. The metol "rodinal" offers no advantage either in point of stability or efficiency as a developer.

S. S.—We expect the stops are marked upon the Dallmeyer system, in which case the aperture marked 18 is approximately $f/13$. The others will then be as follows:—25, $f/15.8$; 36, $f/19$; 50, $f/22.4$; 72, $f/26$. You will understand this is guess-work, because the lens may perhaps be marked on another system, but, as it is apparently a wide angle, the maximum aperture is probably about $f/14$. Of course, you could easily ascertain the F numbers experimentally by measuring each stop with a wedge-shaped strip of card, successively dividing the focal length of the lens by each of the diameters thus found. The result will be the F numbers.

G. Y.—(1) We do not advise you to do more than to rub the surface of the enlargement with stale breadcrumbs. Take the crumb of a loaf two or three days old and break it up until the grains are as small as rice. Cover the print with these, and gently rub with the flat of the hand. When the crumbs become dirty, throw away and use fresh. Any marks which resist this may be removed with soft rubber, not eraser. (2) First give your calico a coating of size or cooked starch. When dry, use any good plain distemper. "Kalko" background paint, which you can get from the Vanguard Co., Maidenhead, or any dealer, is easily mixed and applied.

D. V. E. (1)—Cold weather certainly makes the blind of the focal-plane shutter a little stiff and therefore slows the shutter, but in such moderate climates as that of the United Kingdom we do not think it is a material objection. If the shutter is worked a few times in a warm place before taking it out of a day it works freely enough even in the winter. But apart from this the speeds marked on focal-plane shutters are almost as much at variance with the actual speeds as those on between-lens shutters. (2) One can only give a general opinion, but a well-designed and made shutter ought to work reliably without need of repair at any rate for one year or two.

B. W.—We think it will be difficult in any single negative to get the title to print in black on the white ground, whilst at the same time getting a good reproduction of the tones of the photograph. If you can develop the negative of the photograph so that the surround is dense enough to print white on the print, could you not take a separate negative of the titles on a process plate and add this to the main negative, as is done in printing titles on view postcards—that is to say, stripping the title on to the main negative from a plate negative? We do not think that printing the titles in any other colour would help matters. The use of a slow panchromatic plate in conjunction with a light-filter might perhaps serve to get over the difficulty.

B. W. G.—With the 8-inch lens you would be able to manage very well with the window alone for heads and sitting figures, but you would have to bring the sitter too far away for full lengths, for which you would require artificial light. If you can possibly get electric current, you would do well to instal a couple of 1,500-c.p. half-watt lamps, which would be better than the best gas light, and, we should say, would not cost more to run. If you must use gas, Griffin's "Howellite" lamp is a good model. You could probably obtain a lamp second-hand by advertising. For this light you would require the most rapid plates, and these must be isochromatic. The drawback to gas is the great heat which is generated in the room.

C. Swift.—It is a very old idea to mix albumen with gum in the coating for the gum-bichromate process. We quote a formula, etc., which is not substantially different from yours:—

Bichromate (solution A)	1 oz.
Gum arabic, finely powdered	½ oz.
Albumen, white of egg, beaten up	2 drs.
Glycerine	½ dr.
Pigment	as necessary.

The solution A is made by adding ammonia to a cold saturated solution of potass. bichromate until the mixture turns red litmus paper faintly blue. In preparing the sensitive mixture, the solution A is warmed, the powdered gum and glycerine added in small doses, then the albumen, and finally the pigment, which is mixed with a spoon or spatula. The mixture should be about as thick as honey, and should be coated thin enough to allow the lettering on a piece of printed paper to show through. The coated paper should appear glossy when dry. If it is matt, there is too little gum. Too much albumen lowers the sensitiveness.

Contents.

SUMMARY.

A paper by F. M. Walters, jun., and R. Davis has recently been published by the Bureau of Standards, Washington, recording a detailed study of the use of the chief sensitising dyes for the colour sensitising of plates by bathing. The method of testing is described and working details given of the use of pinacyanol and other colour sensitisers. (P. 416.)

In his "Paris Notes," M. L. P. Clerc refers to some of the commercial and educational applications of cinematography which are taking place in France, and also to current events in colour photography. (P. 413.)

In a contributed article, Mr. R. R. Rawkins refers to the advantages of the extra-contrasty grades of bromide paper for dealing with the quantity printing from amateur film negatives. (P. 411.)

By the use of the selenium single-solution sepia toner in conjunction with Farmer's reducer, a German experimenter has obtained two-colour effects (double toning) on development papers. (P. 419.)

A particular fluoride salt, known as acid ammonium fluoride, is recommended for the removal of the gelatine films from old negatives. The films may be removed whole, leaving the glass clean. Nevertheless, we utter a caution against much immersion of the fingers in such a solution. (P. 410.)

An article by "Thermit" records experience in the use of tanks and other accessories of metal in the use of photographic solutions, and incidently describes how to make a clip for the handling of film bands in the developer. (P. 412.)

Mr. E. A. Bierman outlines the experiments by which he has been led to include the diffraction phenomenon in the calculations relating to diaphragm aperture and screen distance in half-tone negative making. (P. 415.)

In a leading article we refer to some of the forms of damage which a lens may sustain, such as scratches, chips, and other markings, injury to the cementing and strain due to shock from a fall or blow. In some cases the damage may be ignored; in others the expert skill of the optician, preferably the maker of the lens, is required. (P. 410.)

Next year's Photographic Convention is to be held at York. (P. 423.)

A non-focal-plane reflex camera and a cinematograph projection lens of greater efficiency are among the patents of the week. (P. 420.)

Inks containing wax have been recommended as a means of producing oil prints of matt surface. (P. 410.)

In copying sepia-toned prints a colour-sensitive plate is practically a necessity; a light-filter used in conjunction with it is often an advantage. (P. 410.)

EX CATHEDRA.

Turnover and Profits. When negotiating for the purchase of a business, the prospective buyer will do well to ignore the amount of the gross takings, and to ascertain very clearly what the net profits amount to, or, more accurately, what he may expect to draw in return for his own labour and interest on capital. Many photographers are quite satisfied with a business which pays them a decent operator's wage, plus interest on capital invested, there being no "profit" in the sense in which an accountant would use the word. It must always be borne in mind that there are certain standing expenses, such as rent, rates and taxes, upkeep of premises, and, except in very small businesses, wages which have to be met. Outlay on materials is in proportion to the business done, and is much greater in proportion in a cheap business than where good prices are obtained. What has to be done is to get down to net profit for the last two years, and upon that judge the value of the business. In a case recently investigated the profits were about forty shillings weekly, yet several hundreds were asked for a very scanty equipment and a short lease of premises which were not too cheaply rented.

* * *

Warm Black or Sepia. There is a decided tendency at the present time to discard the sepia tone and make prints of a warm black colour. This, to our mind, is a move in the right direction, since some of the sepia tones are far from beautiful. We have seen prints recently on exhibition in show cases, which were of a decidedly yellowish tone, giving the impression of a faded or washed-out image. This result cannot please the customer; while a rich, warm, black tone would be appreciated. Many people have an inkling of photography nowadays, and are often liable to blame the maker rather than the process. The varieties of paper now available for warm black tones by development are legion, and it is decidedly easier to get one's colour by a single process than to use a messy bleacher and the objectionable sulphide bath. We all appreciate the elimination of the latter, on account of its penetrating odour, and also of its deleterious effect upon plates and papers stored in or near the workroom. We traced an instance of stained bromide prints recently to the effect of sulphuretted hydrogen given off during toning. The paper was kept in a separate room, quite away from the toning baths, and was in gross boxes. It was found that brown stains always appeared upon the uppermost sheets in any box that had been opened. The true warm black tone approximates in its gradation more closely than any other print to a good platinotype, and, after all, it is the platinum quality we strive after, whether we admit it or not. As to developers, we find that the borax metol-hydroquinone formula gives slightly warm black tones, full of life and sparkle, on almost all the best makes of

bromide papers, not necessarily those expressly made for warm black tones.

* * *

Matt Oil Prints. The objection which is often raised on æsthetic grounds against the characteristic glossiness of oil pigment prints, leads one of the prominent exponents in Germany, Herr Wurm-Reithmayer, to review the methods which may be used for obtaining oil prints of matt surface. The use of solvents of the varnish constituent of the ink is put aside as difficult and by no means satisfactory, quite apart from the danger involved in the use of such an inflammable liquid as benzene or ether. The writer recalls the use for pigmenting oil prints of the Rafælli pencils as employed by painters in oils. Pigmenting with these yielded prints of agreeable matt surface; and their composition then led Herr Wurm-Reithmayer to try the effect of pigmenting with an ink containing a considerable portion of wax. By making up a mixture compounded from beeswax and ordinary typographic ink it was found that the prints pigmented with it yielded a completely matt surface. It is not suggested that the production of a matt surface by an ink containing wax is a new discovery, since wax is commonly added to ink for the proofing of engravings when a matt effect is required. But the author emphasises the convenience and greater cleanliness of a wax ink, and expresses the view that makers of requisites for oil printing might well place such inks upon the market.

* * *

Copying Toned Bromides. A sepia-toned bromide print, especially if it be vigorous, is by no means an easy subject to copy, and there are probably few photographers who get the best possible result. This is due mainly to disregarding the non-actinic colour of the image which necessitates not only a long exposure but also demands the use of a colour-sensitive plate. It might be thought that with a monochromatic original, a sufficiently prolonged exposure would give full details, but a little thought will show that if a deep yellow half-tone is sufficient to prevent any action upon the emulsion, any darker details, although clearly visible to the eye, must necessarily be lost. A colour screen, although not indispensable, is beneficial; even if there are no apparent blue or violet rays visible, yet they exist in the light reflected from the surface of the paper independently of that coming from the actual image. This is shown to perfection when copying an old varnished painting, where the screen cuts out all superficial light and gives true value to the pigments.

* * *

Cleaning Films from Negatives. On the commercial scale the films are usually cleaned from old negatives by dipping for a few seconds in a hot solution of caustic soda or potash, by which the film is so softened and disintegrated that it can be quickly cleaned off completely with a stiff brush. The method is open to the objection that with some qualities of glass and also, as appears to be the case, with negatives which have been treated with alum, the glass is left in a slightly opalescent state and, therefore, is useless for the purpose to which such waste negatives are usually put, namely, in the various photograph frames sold by stationers. In a recent issue of "Photographische Rundschau" a different process is very strongly recommended. It consists in the use of a cold solution of acid ammonium fluoride of 1 to 2 per cent. strength. A stronger solution is found to exert a certain matting effect on the glass, but in a solution of the above strength the gelatine film becomes partly detached within a few seconds and can be removed whole, leaving the glass perfectly clean. We should not be inclined to recommend continuous immersion of the hands in such a solution, but no doubt on the quantity scale plates could be immersed in the solution in racks and given a rinse in plain water before removing the films. In this way contact of the fingers with the fluoride solution could be almost entirely avoided, and that, we think, is very necessary if the danger of serious skin affection is to be eliminated. Apparently, a very little of the fluoride goes a long way; it is stated that 7 ozs. of the solution serve for clearing the films from 150 to 200 quarter-plate negatives.

DAMAGED LENSES.

A PHOTOGRAPHIC lens, if treated with reasonable care, should remain in good condition for many years; in fact, more than an average lifetime. Many lenses bearing the name of Andrew Ross, who died in 1859, are still in daily use, and are in good working order. Some of the more modern lenses, owing to the use of unreliable glass during the period of experimentation in anastigmatic construction, show signs of surface tarnish, but, fortunately, these are comparatively few in number.

Yet there are many ways in which a lens can be ill-treated; in some cases the damage is irreparable; in others it can be more or less repaired and the instrument restored to its original usefulness. It is not recommended that any considerable trouble or expense be incurred with lenses of little value, as such can usually be replaced at less than the cost of repair, but good lenses, especially if of large size, are well worth attention.

While the amateur optician may effect certain improvements in the metal work of a lens, he is strongly advised never to meddle with the glass components, for he will probably find that after passing through his hands, the last state of his lens is worse than the first. All such work should be entrusted to a skilled optician, and if the original maker is still in business, to him alone should the lens be sent. Serious repairs are apt to be somewhat costly, but as a rule money so spent is well invested; even if the cost of replacing a damaged combination is half the original cost of the lens, it is cheaper than buying a new instrument. It must be realised that only the maker knows the exact quality of glass used for any particular batch of lenses, and the curves to which it was ground.

The most common injury to lenses consists of a general dulling or de-polishing of the exterior surfaces, or more or less distinct scratches or "digs," the latter being usually due to allowing the lens to knock about without protection in the camera case. The former trouble, though not so unsightly, is the more serious one of the two; if it exists it is impossible to obtain bright negatives, the diffusion of light from the dulled surface degrading all the shadows and often creating a false impression of over-exposure. This condition may or may not be easy to remove; in many cases, an application of the polishing tool and putty powder restores the original surface. Scratches are less easily dealt with. As they penetrate a certain distance into the glass, the surface has to be entirely re-ground and polished, which not only reduces the thickness (often an important factor), but alters the figure or curve. It may be necessary to explain that it is usual to grind a lens of slightly larger diameter than its ultimate size, and then to "edge" down the imperfect margins. Obviously, this cannot be done with a finished lens, so that it is often necessary to cover the margin of a re-worked lens with a narrow metal ring which, while slightly reducing its rapidity, ensures perfect

definition. But the scratches may be merely an eyesore, and do not appreciably interfere with the performance of the lens. If they are small, they may be ignored, but if wide and deep it is advisable to rub a little black varnish or printing ink into them, so that they appear as black lines upon the surface instead of white ones. No traces of the black pigment must be allowed to remain except in the scratches. There is no danger of the scratches, when filled, affecting the negative. It may not be generally known that if a shilling be cemented on the centre of the front of a large lens, say, three inches in diameter, and an exposure made at full aperture, no sign of its presence can be found upon a negative. It is only when the size of the diaphragm aperture approaches that of the obstruction that it becomes visible, and such a condition cannot exist in the case of a scratch.

Conchoidal or "oyster-shell" chips sometimes occur on the edges of lenses. If ignored, these will cause a general fogging, but when painted out with black varnish become innocuous. Even a lens broken across the centre may be cemented together with black varnish and be made perfectly usable. If a transparent cement, such as Canada balsam, were used, there would still be a sufficient difference in refraction to cause a scattering of light.

Very often an injury to the cementing between the components of a lens is mistaken for a crack or chip. As a rule, if prismatic colours are present, this is the case, and the trouble can easily be removed by re-cementing, which can be done by anyone used to the work. It may be as well to state that the Canada balsam, as used by opticians, is very different in consistency from that used by microscopists or for cementing colour filters, being a hard resin, liquid only at a high temperature and not a varnish-like liquid. A fair amount of skill and access to proper appliances is necessary if the contact is to be perfect and the glasses properly centred.

Lenses frequently receive injuries from falls, blows and other shocks which are not apparent to the eye, but seriously impair the definition. Glass is not the rigid, unyielding substance it is generally supposed to be, and when the brass mounting of a lens is bent or distorted, the strain which is put upon the glass upsets all the optician's calculations, and may turn the finest anastigmat into a "soft focus objective." It is therefore wise to test thoroughly any lens which has had a fall or any bad strain before using it upon an outdoor job. The condition produced is fortunately only temporary, and making a new cell or re-turning the old one is all that is necessary.

Nearly all the ills that lenses are heirs to may be avoided by providing them with cases in which they can be kept when not actually upon the camera. If this be not done, at least a well-fitting cap should be provided for both back and front cells. Rust or tarnish upon the surfaces, unless very bad, should be ignored; above all, no attempt to polish it off by hand should be made. It may make the lens slightly slower, but now ortho-chromatic plates are in general use, this will hardly be appreciable. Lenses showing any trace of this defect should be kept in an airtight case in as dry a place as possible.

BROMIDE PAPER FOR D. AND P. WORK.

Many portrait photographers are now undertaking developing and printing for amateurs, as a "side-line" in most cases, but I heard recently that it bids fair in some instances to oust the principal line in activity and remuneration. One photographer told me that his newly-formed "D. and P." department proved a veritable godsend to him, and to others who find portrait work slack and money "tight."

From a considerable experience of amateurs' fads and fancies, I find that a large number of "button-pressers" prefer to send their films to a professional photographer who undertakes this class of work. They argue that it is his trade and they can rely upon perfect technical work, whereas the local chemist may relegate the job to a junior assistant to do in his spare time. Some years ago there was undoubtedly much slackness in this direction, but at the present time most chemists have properly organised departments for D. and P. work, whilst some put the work out to reliable trade houses; still, the fact remains that the average amateur feels safer in entrusting his work to a professional photographer.

The introduction of slow development papers of the gaslight type necessitated a change in the exposing apparatus, and most photographers are now in a position to print on gaslight papers. As the bulk of amateurs' negatives are under-exposed, it is necessary to print them on a vigorous grade of paper, and printers were not slow in taking advantage of the "cast-iron" gaslight paper, but nowadays there arises the inevitable questions of speed of production and cost of working.

High-power electric lamps are expensive; they use up a lot of current, and the exposures on gaslight paper from some negatives may be unduly long. The chief reason why the vigorous gaslight papers are so much used is the ease with which brilliant prints can be obtained from poor negatives, but there are now several makers who market bromide papers that will give all the contrast that gaslight will give. Extra-Contrasty, Extra-Vigorous and Extra-Hard are some of the names given to these grades.

There is certainly a good deal to be said in favour of bromide for D. and P. work now that there is a grade for "ghosts." It is a curious thing, but when a customer orders enlargements from certain of his films it is invariably found that these are the poorest of the lot from a quality point of view. Here then is the opportunity to use this extra-vigorous bromide paper. Press photographers have for years used a hard paper made specially for the production of brilliant prints from their high-speed exposures, but the manufacturers have lately given us papers of still greater contrasts. The speed is about one-half that of ordinary bromide paper, and any of the usual developers can be used.

For brevity's sake I enumerate below the principal advantages of bromide paper over gaslight paper for D. and P. work:—

1. There is a saving in the light bill.
2. The printing box is cooler and the films less inclined to curl.
3. Little or no tendency to greenish blacks by over-exposure or to very blue colours by under-exposure.
4. No tendency to stain suddenly if left in the developer a trifle longer than usual.
5. Will stand handling, and not so liable to deteriorate in an impure atmosphere.
6. Will tone well in the sulphide bath.
7. Will give nice tones in the hypo-alum bath provided the prints receive about one-third more than the usual exposure and are developed in a restrained developer.

R. R. Rawkins.

DARK-ROOM METAL WARE.

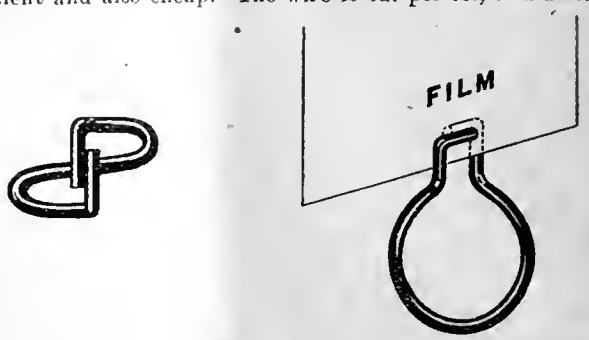
The problem of metal-ware, in its relation to plates, film, papers and photographic chemicals, is one which sometimes gives the photographer serious food for thought. I am not going to solve the problem, or even attempt to analyse it scientifically, but having had a rather extensive experience of dark-room metal-ware, I may be able to give a few hints that will help the practical man.

Metal implements used in photography have their principal significance through their possible and probable reactions with developing and fixing solutions. If it were not for these reactions, any old metal might be used with impunity for the construction of racks, tanks, dishes, etc. As it is, the most innocuous metallic compositions yet devised cannot be considered foolproof.

If an implement comes into contact with developer only, my experience is that most metals are quite safe while clean, but they must be scrupulously clean. If the same tank, rack or rod goes also into contact with the fixing, the problem is first extended but may be ultimately simplified. Simplified, if the metal used is one of the usual alloys, though it might not be so with every pure metal. The extension of the problem is due to the fact that fixing baths, and particularly the modern acid fixing baths, will attack many metals which are safe in developer; the simplification is due to the ultimate silver plating done by the same baths.

My first experience of using metal implements for developing aids, was with a type of rack which is still obtainable from Messrs. Kodak, Butchers, and David Allan. This rack appears to be made of nickel-plated copper, and carries from whole-plate downwards, small plates being accommodated by means of a movable partition. It is provided with hooks and can be hung in any deep tank or washer, the ability to deal with huge quantities of mixed-size plates being a marked feature of the type, as any number of racks can be hung one under the other, provided the tank is deep enough. I have used one of these racks constantly for three years without a stained negative, but I believe there is a lot in the way the rack is handled. I load it with one plate only to each groove, and do not disturb the plates again until they are *dry*. That is to say, the rack goes through the developer, washer, fixer, washer, and is dried without being touched by brush or cloth. I have known the same type of rack to be overloaded—in the interests of economy—two plates being forced into each groove. The result was a batch of metal-stained negatives due to the scratched surface of the grooves, and in a very short time the same rack fell to bits. I have also known stains when such a rack has been assiduously scrubbed, the scrubbing taking off the original plating and any subsequent silver coating also. My own racks at the moment are white with silver from the fixing baths, and are consequently quite innocuous. What I have said about racks also applies to tanks, but I think the rack is easier kept clean. I do not use metal tanks now, and if I did I would prefer to have separate tanks for each solution.

Photographers who handle quantities of amateurs' films require rods to suspend them in the tanks. These rods are usually metal. Why, I don't know. I would prefer vulcanite or something like that if I could get it, and I have thought of glass, but decided not to risk it with dark-room hands. The orthodox rod is costly—or was when I bought any last—and it is up to the photographer who likes investigating things to try substitutes. I tried copper wire. It worked very cleanly, soon putting on a nice coat of silver from the fixing, but it was not strong enough. Various other things were tried, with the result that I finished up with tinned iron wire of a thickness of about $\frac{1}{8}$ in. I do not know the technical gauge, but the wire will bend to any desired shape, is strong and lasting, and has sufficient spring to make film clips as well. This wire has worked well for a long time, the only thing about it being that it is likely to rust if the plating is scratched, and rust is mischievous. The following system answers to prevent trouble. Every day, before any rods or clips are used, they are all gone over with a stiff brush. This leaves them free from any traces of rust or any other foreign matter. When put into action, they go right through the whole gamut, and when released from the spools are merely thrown into a wire box to dry. They have no apparent action on the solutions, or their activity, though I remember some years ago getting a batch of purple negatives from a wooden tank into which some tinned iron wire had been dropped accidentally. In that case, the wire had lain for some time before the colouring appeared, and in spite of the stain the negatives were beautiful printers. Standard film clips are, in my experience, usually to be relied on, but the wire ones I have mentioned are certainly efficient and also cheap. The wire is 6d. per lb., and 1 lb. will



make about 30. To make a clip of this kind, it is only necessary to cut about 8 ins. of wire, and bend it as shown in the sketch. The requisite amount of spring can easily be got by opening it out the wrong way, and forcing it back gently. This clip will firmly grip the two ends of a spool, and is quite heavy enough to sink the largest size single or double, while not too big for small sizes.

Pack film is the despair of many developing firms. There are some, in fact, who will not take orders for developing packs. But there is nothing very troublesome about packs if hangers are used in conjunction with the usual film tanks. Such hangers, in different types, are supplied by Kodak and Houghtons, and they are very efficient. I have also developed packs by threading them on thin twine and dropping down the tank without any weight. They must be released and hung separately to dry when this dodge is used.

A useful implement in the dark-room is a Hotchkiss paper punch. A large batch of spools can be virtually halved by punching them up in pairs, the little metal rivets being quite safe provided they are driven through the blank ends or edges of the spools. They can also be used to string up a pack into one long film, but great care must be taken in placing the rivets in this case.

With papers, metal does not figure to such an extent, but we have enamelled dishes and galvanised washers. The former get scratched, and the latter are subject to the action of traces of acid fixing. I have never noticed or suspected any bad results from an exposed patch of iron in an enamelled developing dish, but hypo, alum, or acid fixing baths have at times caused stains from this source. Galvanised washers appear to be quite all right when plain hypo is used, and also when hypo and metabisulphite are the sole constituents of the bath, but there is a doubt when we come to other acid baths. To test whether a washer is safe, take a print fresh from the fixer and place it in contact with the bottom of the washer. If no mark is caused on print or washer, things are in order,

or at least there is no obvious cause for alarm, but using acid baths, I have had deep brown and black stains on the washer by this test. Such marks would appear to be due to sulphurisation of the zinc surface of the bath, and such action is not what one would desire in contact with the face of a print. The technical details of what happens, and what might happen, I will leave to the research departments who are better equipped for such problems, but it appears to me to be a safe policy not to use acid baths in conjunction with galvanised washers. Using plain hypo, I have found galvanised circular basins, 18 ins. in circumference and 10 ins. deep to make excellent washers. Holes are bored or punched round the perimeter about 1 in. from the top, and the water enters from a hose in the centre and 1 in from the bottom. The prints do not lie in a heap, and are reasonably hypo free with a relatively small amount of water. Such basins can be picked up from surplus Government stock at nominal prices.

Concluding, I might mention some interesting tests I made with stainless steel, samples of which were supplied by the manufacturers. I found this metal resisted developers well, but immediately turned ebony black on immersion in an acid fixing bath. The safety and durability of this black plating I was unable to determine, but I hope some day to try this metal again. Some deleterious action took place with the fixing, but it is possible that this would cease when the change in the metal's surface had reached a certain point. This is another item I will recommend to the research people as possibly worth investigation. THERMIT.

PARIS NOTES.

THERE have been quite a number of signs of renewed photographic activity in Paris since my last letter. These, in the order of their occurrence, are the exhibition of the French Physical Society, an exhibition of cinematography applied to scholastic purposes, the Paris Fair, the re-opening of the Salon du Gout Francais and a very interesting exhibition of his pictorial works by Commandant Puyo.

Scientific Photography.

At the exhibition of the Physical Society M. Prélhumeau showed his apparatus for stereo-photo-topography already described in these notes (B.J., March 19, 1922, p. 295). The well-known instrument maker, M. A. Jobin showed the microphotometer of Fabry and Buisson for the measurement of densities in photographic negatives, especially for the study of the distribution of light in spectral rays; also a universal photometer by the same designers for measuring stellar negatives or negatives to be used in photo-topography. M. E. Bouty, a maker of astronomical instruments, exhibited a new model of machine for the measurement of multiple movements with great exactitude. Lastly, MM. H. Calmels showed some new grating replicas of large size cast from an original Roland grating by a Parisian astronomer. M. E. Annequin, for the construction of spectrographic cameras used in the examination of light-filters and in measurements of the colour-sensitiveness of emulsions. In addition to these scientific instruments, the exhibition included Eastman Duplitized X-ray film, Wratten light-filters, Guilleminot plates and papers and stereoscopic cameras of Jules Richard.

Cinematography and Projection.

For some months past there has been a very active propaganda in France for the wider use of the cinematograph in schools of all degrees and particularly in those for young children. The movement has already borne fruit, for several municipalities have acquired cinematograph outfits for use in schools. The town of St. Etienne (Loire) has provided each of its schools with a cinematograph projection outfit. Films for these purposes are obtainable on free loan from a department of the Ministry of Public Instruction, which for many years past has circulated collections of ordinary lantern slides throughout France. Not only is the loan of these films made without charge, but the films are sent here and there gratuitously by the postal service. At present the stock of cinematograph films is not a very comprehensive one, but the work of making it such is being actively pushed forward by producers with the assistance of several publishers of school books and medical and scientific works.

An association in Paris which goes by the name of "L'Art à l'Ecole," and includes among its members some artists and people interested in juvenile training, has recently held a congress for determining the lines which should be followed in the production of films for use in schools, in which work it has received the support of public authorities and the municipality of Paris. The congress was made the occasion of an exhibition on the premises of the Conservatoire National des Arts et Metiers of types of cinematograph projector and accessories most suitable for use in schools of various degrees from those for the youngest children to the universities. Simple and strong projectors were shown, in particular by MM. Aubert, Gaumont, Mollier and Pathé; also some machines of extremely simple construction, among them some home cinematographs shown by three firms, the Cinoscope Co. and M. Milior and M. Laval.

The same machines were included some short time afterwards in the Paris Fair with the addition of some additional models. One of these, the "Lumicycle" of MM. Gaumont, is a cinematograph projector for school use in which the current for the electric lamp is supplied by a small generator which is driven by a wheel operated like an ordinary bicycle. Students take turn in mounting a saddle and working the pair of pedals which generates the light for the projection. MM. Pathé-Cinema showed a miniature Baby projector and a cinematograph camera for amateurs, both using film of less than standard size, i.e. of width just under 1 in.

An interesting new introduction is the "Business Cinevalise" of MM. Mollier, a cinematograph projector completely enclosed in a container of the form of a suit-case. By connecting an electric terminal to the holder of any electric lamp, this miniature apparatus allows a commercial traveller to show projections of his goods to customers whom he visits. Film of standard width is used, and a projected picture of about 9 x 7 in. size is shown on a translucent screen which is shielded from external light by dark curtains. The motion pictures can thus be exhibited almost anywhere.

At a stand in the Paris Fair an exhibitor of the "Orthotrope" concave projection screen sought in vain to convince visitors that the image projected on this screen gave a relief effect. At the same exhibition a stand of the Department of Scientific and Industrial Research and Inventions (a branch of the Ministry of Public Instruction) had been converted into a projection theatre for the demonstration of stereoscopic projection by polarised light re-invented by M. P. Toulon. The process in no wise differs from that patented and practised in 1891 by John Anderton of Birmingham (B. J. Lantern Record, 1892, Oct. p. 6 and 1899, Jan. p. 6). It is a thousand pities that a state department should employ its funds for subsidising the re-invention of uncommercial processes or, as in the present case, of methods which have been known for years.

In the field of ordinary optical projection an exhibit at the Paris Fair was the Silf outfit, in which the transparencies, to the average number of 25, are supplied on a band of film. There was also shown the automatic Pircus projector of M. G.

Massiot, designed for luminous advertisements, in which views are arranged radially in a cylindrical basket and are caused to come successively into the lantern stage.

The same constructor shows two further models of optical lantern, one designed particularly for the higher grades of school and serving for either cinematograph or still projection, the latter of ordinary lantern slides, solid objects, and also objects arranged horizontally on a glass plate or in a transparent dish of water, or of microscopic preparations. The other lantern is constructed for the projection of Autochromes and other colour transparencies, and at a distance of 18 ft. gives a very bright image at a magnification of about 16 times. The light-source is an incandescent lamp consuming 2.5 amperes at 110 volts. Two of these lanterns can be used together for the production of dissolving views. A rheostat allows of the light in one being gradually lowered whilst that in the other is brought to full power.

I must also mention the production by the firm of Bauchet of a new non-flam cinematograph film in which the picture is formed in the interior of a film of cellophane and not, as has hitherto been the case, on the outside surface of the support. The film is at present made only in less than the standard size for use in home cinematographs, but it is intended to produce it in the normal size.

High-Speed Photo-Analysis of Movement.

Chrono-photography of ultra-high frequency for the analysis of extremely rapid movement has been hitherto attempted by means of rotating mirrors, serving to record the successive phases of a moving object. Since 1904 M. Lucien Bull, the successor of Marey, inspired by the results obtained by Marey, Mach, Boys, and Wood respectively in 1879, 1885, 1890, and 1903, has used electric sparks in rapid succession as the source of light. The moving object, which may be an insect or a projectile, moves in front of a condenser by which the image of the spark is projected on to the lens. The duration of each period of illumination is so short that whatever the speed of the moving object or of the displacement of the sensitive film, the image is formed with critical sharpness. In these first experiments the frequency of the sparks was regulated by the contacts of a rotating electrical interrupter, similar to the collector of a dynamo, mounted on the same spindle as the drum (about 3 ft. in circumference) to which the sensitive film was attached. In this way from 50 to 60 photographs could be made with an interval of about 1-1,000th of a second between each pair. This first primitive device provided the means for numerous researches, and M. Bull has now improved it in many important respects as the result of his work during the war in the study of the movements of projectiles from small arms and from guns of very small bore. With the aid of MM. Abraham and Bloch he has been able to record up to 200 images on a rotating film of 3 ft. in length at a rate of 10,000 per second. The sparks obtained by the oscillating discharge between two aluminium hemispheres of a small condenser (itself supplied by a condenser of large capacity) have a frequency which is constant within 1 per cent. and is adjustable at will over a considerable range. The duration of the spark is about one five-millionth of a second and its actinic brilliancy about 160 times that of a 12 ampere arc, or 16 times that of the sun.

The only limit to the frequency with which the images can be recorded is that of separately recording the pictures on the film. It is scarcely possible to give to film mounted on a drum of 1 ft. diameter a peripheral speed of more than 165 ft. per second. Hence with a frequency of 10,000 images per second the height of each image cannot be greater than about one-fifth of an in. (5 mm.).

Without altering the electrical device, M. Bull has recently been able to go further as regards separating the images by rotating the photographic part of the apparatus. The film is arranged on the inside of a fixed cylindrical drum of 1 ft. diameter and receives the images formed by a lens, the axis of which coincides with the geometrical axis of the cylinder. The images are diverted to the film by means of a total reflection prism. The small weight of this prism allows of its receiving a speed of rotation of 160 revolutions per second, corresponding with a speed of displacement of the image on the film equal to 1,660 ft. per second. Thus, the images recorded on the film at a frequency of 40,000 per second are half an inch in height, or quarter-inch in height at 80,000 per second. The only drawback to this arrangement is that the images are turned on themselves at the same time that the prism traverses the circumference on which the film is mounted. For the cinematograph projection of a film thus obtained it would therefore be necessary to use an apparatus similar to that employed in taking the pictures, correcting the orientation of the successive images when printing on the positive film.

Colour Photography.

The Salon du Goût Français, after its successful season last year in Paris, has been warmly received on its travels in the United States, in New York, Philadelphia and Chicago, and has now been re-established at the Palais de Glace, Champs Elysées. This collection of nearly 2,000 Autochromes, most of them measuring 16 by 17 in., and of coloured transparencies, has aroused the greatest interest among manufacturers and merchants as well as in the minds of the public as regards the advertisement value of photography and particularly of colour photography. Most of the Autochromes are perfect examples of the process and many are of extremely difficult subjects. They are shown in panels of a handsome design which adds to their attractiveness. The exhibition, which remains open until the end of August, should most certainly be visited by any of my readers who are passing through Paris.

One of the notable portrait studios in Paris has recently been taken over by the Dufay Patents Company (originators of the Omnicolore plate no longer made) for the exploitation of a process of colour photography, the secret of which is being closely guarded. Specimens have been shown only to a very few people and even to them under the greatest secrecy.

Attempts have recently been made in France to negotiate the patents of Dr. A. Traube of Munich for the Uvachrome process, and a demonstration of this process has been given to the French Photographic Society by the Swiss company interested in its exploitation. The three negatives are made in rapid succession on a single plate by means of a repeating back which falls vertically between two successive exposures, its movement controlled by an air brake. The shutter release is connected to that of the repeating back so that their movements alternate without loss of time. It seems to be thought that the fact that the three exposures respectively through the three light-filters are equal constitutes an extraordinary invention, although such equality has already been attained in three-colour cinematography, whilst it is likewise obtainable without difficulty by increasing the opacity of the more transparent of the light-filters in a three-colour set by means of a neutral grey pigment. After development of the negative a print is made on a film of the same quality as positive cinema film. This print is then treated in a mordanting bath of copper ferricyanide and the three images are then dyed respectively pink, blue-green, and yellow. The dyed films are washed and dried and superimposed in register without being cemented to each other. The influence of the purplish-red colour of the mordant appears to have its effect on the greens of the coloured picture which were very dark in almost all the specimens shown.

Support is also being sought at the present time for a two-colour process of colour photography, the novelty of which is scarcely perceptible. A blue carbon print is superimposed on a P.O.P. print which has been toned red. Probably, in order to make still more certain that the two images shall not register, they are made respectively from the two negatives of a stereoscopic pair!

At a recent meeting of the cinematograph section of the French Photographic Society some sections of the two-colour film, " The Glorious Adventure " made by the Prizma process of W. van Dorn Kelley were shown and received a most favourable verdict. Part of the film representing a fire was of special merit.

L. P. Clerc.

SYSTEM IN HALF-TONE OPERATING: THE MISSING FACTOR IN THE NORMAL EQUATION.

In the " Process Year Book " for 1903-4 I wrote on the subject of constant ratio stops, constant screen separations, and exposure in half-tone operating. The subject at that time was not new to me, as I had been working along these lines for several years. I have continually advocated one-stop negatives, basing my contentions upon the belief that one stop would produce gradation nearer to the theoretical straight line than any combination of two or more stops. The general principle was adopted in our operating, but often departed from in the case of difficult copies, and more especially with coarse-screen work, but not always to the benefit of the result.

My faith in the principle, however, was never shaken, although I realised that there was a weak spot somewhere which had eluded me. In the first place, the stops were worked out for an average copy only, and any variation from the normal was, more or less, a matter of judgment, and, as all operators did not think alike, the standard negative did not always materialise. With continual practice along these lines, however, our operators produced a very good average of negatives in large quantities up to the outbreak of the War in 1914, when, in common with other houses, our staff became so depleted that we had only one operator left. Early in 1918 our only operator was taken seriously ill, and I had to take over the work at a few minutes' notice, not having touched it during the previous 3¼ years.

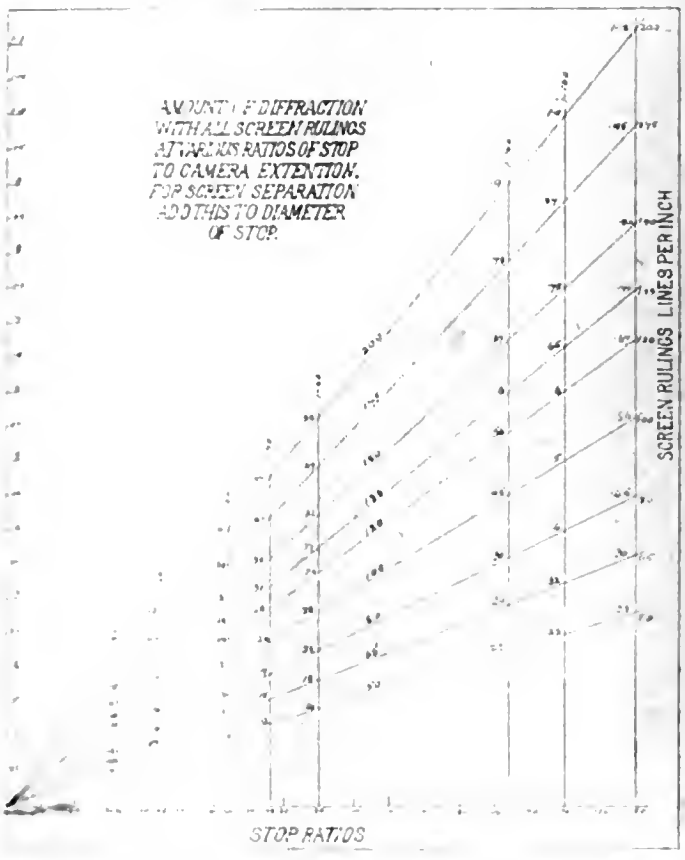
It was during this period that I evolved a system of classifying copies into five grades, and assigning a definite stop ratio and exposure to each grade at a fixed screen separation for all grades with each ruling. This was a step forward, but I was still dissatisfied because the screen separations had been found by trial and error methods, and I could not find any formula that would agree with the separations so found, and which were giving perfectly satisfactory results under the fixed conditions stated. It was found that the normal separation was satisfactory for 50 and 65 line screens, but as the rulings became finer the separation became gradually less, until the 200 line working distance was only a little more than half the separation indicated by the normal equation.

It only remained now to find the reason for these variations, and, although I believed that diffraction was playing a large part and spent a great deal of time in trying to locate the effects at the focal plane, I did not meet with much success.

In the autumn of last year, while still working on this problem, I was attracted by the halo surrounding the lens opening when illuminated by light reflected from a sheet of white paper, and viewed from the back of the camera through the screen. Changing the rulings from fine to coarse, it was noticed that the halo surrounding the lens became narrower, and that changing the stops with the same ruling also produced very marked changes in the width of this halo in relation to the stop diameter.

These halos were at first sketched and comparisons made, and afterwards photographed with a telephoto lens placed as near to the back of the screen as possible. From the results of these experiments I have plotted the size of the halo in relationship to the screen rulings, and to stops of different ratios to extension, the result of which is shown in the graph below.

The cause of the halo is undoubtedly diffraction, and is seen by the eye as the result of the interposition of a number of screen lines, the finer rulings producing the wider halo. I have no mathematical proof to offer that this is the form in which the dot is projected by the screen opening upon the photographic plate; the evidence is entirely circumstantial, but the closer I study the problem the more confirmation I obtain that, whatever is the cause, if the measurement of this halo is added to the diameter of the stop, the equation will then indicate the screen separation which will work under the conditions that I have laid down. The variations from the separations so found will be caused by varying thickness of line to space, thickness and refractive index of the glass or variations in the balsam sealing. Economic screens generally require a small increase of separation, due, I surmise, to the thicker film of balsam between the lines.



A very convenient stop ratio is 1-64, and this is the one that my system is based upon. It is interesting to note that the decimal measurement of the halo is the same as the denominator of the common fraction of the screen opening.

The normal equation for this ratio with a 200 line screen is:— 1 : 64 : : .0025 : .16 = 4.5 millimetres to screen lines.

The new equation will be:— 1 : 64 : : .0025 : .114 = 2.9 millimetres to screen lines.

I have reproduced a selection of the diffraction halos which will repay study, and will help to make the problem clearer.

B

Fig. 1 is very instructive. The halo is clearly shown as being composed of 8 overlapping circles of the same radius as the stop opening. It has been lined up to represent the relationship of the stop to the screen opening, and of the diffraction halo to the form of the dot in the negative. It will be seen how the least intense illumination is in the direction of the corners of the screen openings, and the brightest portion in the direction of the joining of the dots. It requires very little imagination to see how the square dot is formed from the round stop.

If a comparison is made with Fig. 2, it will be seen how the difficulty of obtaining a good join with a 50 line screen is

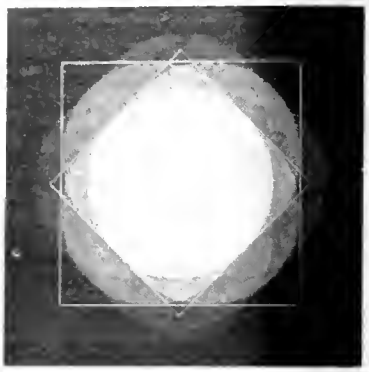


Fig. 1.—Stop 1-64, 200 line screen extra diameter due to halo .4.

easily accounted for. These are photographs of the same stop at the same extension, the only difference being the screen rulings, for which I have purposely selected the two extremes as being a better illustration of the principle.

Fig. 3 illustrates the important part played by diffraction when small stops are used, the photographic effect of which is much greater than the ratio of the aperture alone would

Fig. 2.—Stop 1-64, 50 line screen; extra diameter due to halo .1.

Fig. 3.—Stop 1-144, 200 line screen; extra diameter due to halo .9.

warrant, the effective diameter of the dot being doubled at a stop ratio of 1-160 with a 200 line screen.

I have confined myself to a broad statement of the case only, and must leave any attempt to discuss the application of this theory to practice to a future occasion. I have no wish to dogmatise as to any particular system of operating; my only desire is to bring light into a somewhat hazy and very debatable subject, and I hope that I have said enough to establish what I believe is a new principle in the calculation of screen separations in half-tone operating.

STUDIES IN COLOUR-SENSITIZING BY BATHING.

[A scientific paper, No. 422, recently published by the Bureau of Standards, Washington, is that entitled "Studies in Colour-Sensitive Photographic Plates and Methods of Sensitizing by Bathing," by Francis M. Walters, junr., and Raymond Davis. As will be seen from its somewhat abridged text, which we reprint, it contains the results of numerous trials respecting the best method of using pinacynol and other colour sensitizers, *e.g.*, dicyanine, pinaverdol, pinachrome, orthochrome T. and homocol. It also deals with the increase of speed in panchromatic plates by washing before exposure.]

Plates and films may be sensitized by two methods: (1) The dye may be incorporated in the emulsion at some stage in its preparation, usually immediately before coating, and (2) by bathing an ordinary blue sensitive dry plate in a solution of the dye. In general, the more sensitive plates result from bathing, but bathed plates often have the defect of not keeping.

The amount of dye required for sensitizing is very small. When incorporated in the emulsion, 2 to 4 mg. to 100 ccs. of emulsion give the best results with most dyes, while in bathing the best concentration lies between 1 part in 25,000 and 1 part in 75,000, although much smaller amounts give some sensitizing action.

In order to sensitize, a dye must combine with the silver bromide itself. Further, the dyestuffs which sensitize all fall into the class of so-called substantive dyes; that is, they dye substances directly. The centre of the region which is sensitized by a given dye lies about 20 millimicrons farther toward the red than the centre of the absorption band of the dye.[1] Thus dyes which sensitize for the yellow-green are reddish in colour, as, for example, erythrosin and pinaverdol. Dyes which sensitize for orange are purple, and red sensitizers are greenish. Eder found that the less silver iodide a silver bromide gelatine emulsion contained the better it sensitized. Silver chloride sensitizes readily, but its original sensitiveness is so much less than that of silver bromide that the sensitized salt does not compare in rapidity with sensitized silver bromide.[2] An important characteristic of a dye suitable for sensitizing is its solubility. It must be soluble in water, or it must at least be capable of forming a fairly stable colloidal solution with it. Dyes soluble only in other solvents—for example, alcohol—cannot penetrate the gelatine in such a manner as to dye the silver bromide. In addition, the dye should be of such a character as not to stain the gelatine so as to prevent the light from penetrating to the silver bromide. Were it not for this necessary characteristic, there are probably many dyes which would sensitize.

Before the war sensitizing dyes were principally imported from Germany. When this supply was cut off, the preparation of the dyes was undertaken by various laboratories in England and in the United States. The Ilford Co. of London produced pinacyanol and pinaverdol, while in this country the Eastman Kodak Co. are making orthochrome T as well. The colour laboratory, Bureau of Chemistry, Department of Agriculture, has prepared pinaverdol, pinacyanol, and dicyanine. The success of these investigators has led to the preparation of entirely new sensitizers which promise marked improvement in panchromatic plates.

While commercial panchromatic plates are now sufficiently rapid for the photography of still objects and for three-colour process work, there are certain problems which demand plates which are either more rapid or which are sensitive to radiations to which the panchromatic plate is not. Those who have these problems find it advisable to use ordinary plates sensitized by bathing. Important among the special problems are those in the field of spectroscopy, in which use is made of dicyanine to photograph infra-red spectra, and specially stained plates are indispensable in recording the visible spectrum of faint sources.

The directions which are furnished by the dye manufacturer for

1. Eder, Handbuch, 3, p. 150.
2. Eder, Handbuch, 3, p. 154.

using the dye for bathing are at variance with the methods used at this Bureau and by some other workers. The work described in this paper was undertaken with the view of ascertaining the relation between the methods developed at this Bureau and the practice recommended by the dye makers.

Since pinacyanol is the most widely used red sensitizer and since good orthochromatic plates may be obtained commercially, the greater part of the investigation was done with this dye. Various methods and conditions of bathing were studied and keeping tests were made on plates sensitized by two methods of bathing. In addition to pinacyanol other important sensitizing dyes were studied.

Methods of Studying Colour Sensitiveness.

In studying the various ways of sensitizing by bathing two methods were employed: (1) The continuous spectrum of a source of white light was photographed on the plate, and (2) the speed of the plate to white light was measured and the filter factors of the plate with a given set of colour filters were determined.

Spectrograph Method.—The spectrograph shown in fig. 1 was designed for studying the colour sensitiveness of plates.

The light-source (*L*) is a 100-watt tungsten lamp whose brightness is kept constant by adjusting a rheostat to maintain a constant current through the filament. Around the lamp is a white reflector (*R*), while in front of the slit is a piece of ground glass, to give uniform illumination along the slit, which is 2 inches high. Between the ground glass and the slit is placed a rotating disc (*D*), out of which is cut a variable aperture such that the exposure

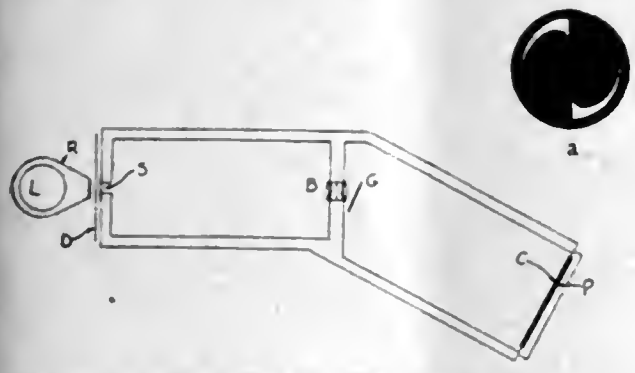

Fig. 1.—Diagram of Spectrograph.
Disc *a* for varying exposures is mounted at *D*. *L* is the lamp; *R*, reflector; *S*, slit; *B*, lens; *G*, grating replica; *c*, wave-length scale in contact with plate under test.

along the slit varies in a fixed manner with the distance from its ends. The series of horizontal lines on the spectrograms indicate geometrically decreasing exposures. The exposure at the first line from the bottom is one-fourth that at the bottom; at the second line, one-sixteenth; at the third, one sixty-fourth; at the fourth, one two-hundred-and-fifty-sixth; and at the top, one one-thousand-and-twenty-fourth. The light from the slit passes through first a photographic lens (*B*), then a replica of a diffraction grating, which disperses it into a normal spectrum. Just in front of the plate (*P*) is a screen (*C*) bearing on it the reference lines which mark both intensities and wave lengths on the plate. The end of this screen, through which the red part of the spectrum passes, is stained with "rapid filter yellow" to screen out the second-order violet light, which in the grating spectrum is superposed on the first order red.

The tungsten lamp used for the investigation does not have the same spectral distribution of energy as does the sun. The tungsten lamp is deficient in the blue as compared with the sun, and is relatively more intense in the red than the sun.

The spectrograph serves as a very convenient means of studying qualitatively the sensitizing action, showing as it does the regions of sensitiveness, both as to extent and as to the location of the maxima, and also, in addition to other detriments, the degree of fog induced by the process. For work of a quantitative character, however, such as a study of the time of bathing or the effect of the proportion of dye in the sensitizing bath, greater exactness is desirable. This is found in photographic sensitometry.

Sensitometry consists in the exposure of a photographic material to a known source of light for definite intervals of time, the development of the material under standard conditions, and an interpretation of the blackening produced on the material in relation to the time of exposure and the intensity of the light acting. The details of the methods of sensitometry used in this work will be described in a forthcoming Bureau scientific paper.

Sensitometry is applied to the study of colour sensitizing by using filters which transmit light of particular colours only. The filters used in this investigation are Wratten A, which gives the red sensitiveness; Wratten G, which gives very nearly the added sensitiveness due to the dye; Wratten B, which gives the sensitiveness to green, and Wratten C, to blue.

The speed or sensitiveness of the plate to the light transmitted by the filter may be measured by either introducing the filter between the light source and the plate in the exposing apparatus or by measuring the speed to white light and dividing this by the filter factor of the plate. When a number of filters are used, the second is the more rapid. The following procedure was, therefore, employed: Three strips from the sensitized plate were exposed in the sensitometer to a light-source having approximately the spectral energy distribution of average noon sunlight, the strips were developed for different times, the densities measured and plotted against the logarithm of the time of exposure, and a speed determination made according to the method of Hurter and Driffield[3]. When used with the four Wratten filters mentioned above, two strips from the plate served to determine the factors of the plate.

The filter factors were measured as described in Bureau Scientific Paper, 309. The principle of this consists in varying the intensity of the light-source until equal blackening is produced with equal exposure time with and without the filter. Since the filter factor gives the ratio of the total sensitiveness of the plate to its sensitiveness to the light transmitted by the filter, the filter factor and the speed of the plate without the filter give the data necessary to determine the speed of the plate with the filter. For example, if the speed of a plate to white light (average noon sunlight) is 400 and the filter factor with the A filter is 10 the speed through the A filter is 40.

The method of stating colour sensitiveness employed by Eder,[4] Sheppard and Mees[5] and Wallace[6] gives the added or chromatic sensitiveness in terms of the blue sensitiveness. This method we believe to be unsatisfactory, because the blue sensitiveness is decreased more or less by any process of sensitizing to other colours and because the ratio of the colour sensitiveness to the blue sensitiveness does not give the best basis for comparison of one plate with another. The question to be answered is, Does this method or that give the greatest sensitiveness to a given colour of light, regardless of what happens to the blue? This question is most directly answered by the speed of the plate to the light in question.

Pinacyanol.

Pinacyanol is, for many purposes, the most important sensitizer. Although it is commonly used in commercial panchromatic plates in conjunction with other sensitizers which give greater sensitiveness in the yellow green, it alone gives a fairly good panchromatic plate.

Water Bath.

The following is typical of the directions given by the makers for the use of pinacyanol. Dissolve 1 part of pinacyanol in 1,000 parts of ethyl alcohol for the stock solution. To make red-sensitive plates bathe ordinary gelatine plates for two or three minutes in the following solution: Water, 200 parts; stock solution, 3 parts. Wash well in running water, or frequent changes for several minutes and dry in total darkness as quickly as possible in a current of warm, dry air free from dust.

If these directions are followed, it is found that the dye precipitates on standing after a plate has been bathed in it, or often before the plate has been sensitized, which results in the plate being spotted and lacking in sensitiveness. Pinacyanol is not soluble enough in cold water to wash away any dye deposited on the plate in the gelatine.

The addition of a little ammonia, potassium bromide, and other electrolytes to the dye bath (water 200 cc., pinacyanol stock solution 3 cc.) causes flocculation of the dye. This may indicate

5. Ferguson, "Photographic Researches of Hurter and Driffield," Royal Photographic Society, London, 1920.

6. R. J. Wallace, "Astrophys. Jour.," 26, p. 305; 1907.

that the bath is not a true solution, but a colloidal solution or dispersoid.

This phenomenon suggested to the writers that the failure of the water bath in sensitizing ordinary commercial plates might be due to the presence of electrolytes in the emulsion. It is customary to add to the emulsion immediately before coating a small quantity of chrome alum to harden the gelatine, so that it will withstand alkaline development at room temperatures. There may also be present various other electrolytes, such as soluble bromides to restrain fog.[7] If present, these soluble salts would come to the surface of the plate in drying and would thus be in a position to cause the speedy flocculation of the dye bath.

Accordingly, we tried washing the plates in tap water before bathing in a water solution of pinacyanol and found that the plates then did not cause the flocculation of the dye bath. The time for bathing is also decreased by this operation, since the gelatine swells somewhat and permits diffusion to take place more rapidly. With a washing time of five minutes the time required for sensitizing is decreased to two minutes.

While not so fast as plates sensitized in a bath containing ammonia, the water bathed plates show considerably less initial fog and also keep much better.

Another point of importance is that if a plate be examined after removal from the dye bath there is found on it a considerable amount of the dye which is not removed by washing in water. In addition, there is a considerable staining of the gelatine, which decreases by its screening action the sensitiveness of the plate. Rinsing the plate in ethyl alcohol after the dye bath will remove to a large extent the dye dissolved in the gelatine, as well as that on the surface, while not affecting that which has combined with the silver bromide and to which the sensitizing action is due. That this is true may be shown by the fact that prolonged bathing in alcohol after sensitizing in the water bath does not decrease the colour sensitiveness. It is common experience that bathed plates must be dried rapidly to secure speed and freedom from fog.[8] In addition, therefore, to furnishing cleaner plates, the rinse in alcohol aids in drying the plates. The drying is accelerated by the alcohol, which replaces to a large extent the water in the gelatine film.

Water, Alcohol, and Ammonia Bath.

It has been observed (particularly with erythrosine) that the addition of ammonia to the dye bath increases the sensitizing action of the dye. If ammonia be added to a water bath of pinacyanol, flocculation occurs and prevents sensitizing. However, ammonia may be safely added to the dye bath if sufficient alcohol be present. Thus the formula used at this Bureau calls for—

Water	60 parts.
Ethyl alcohol (95 per cent.)	40 ,,
Pinacyanol stock solution (1 to 1,000)	4 ,,
Ammonia (28 per cent.)	4 ,,

For ordinary work this quantity of ammonia usually gives too much fog and is recommended only in the case of plates which are used for position measurements, as in spectroscopy. If the amount of ammonia be cut from 4 to 2 ccs. the sensitizing action is nearly as great and the fog is much less. Compared with plates bathed in water and pinacyanol, the sensitizing action is twice as great. The sensitizing action of a bath composed of water and alcohol with no ammonia is less than the bath containing water only. For use in spectroscopy the ammonia method has the particular advantage of extending the region of sensitiveness, so that lines further in the red may be photographed.

It should be emphasised, however, that ammonia as a sensitizer reduces the keeping qualities of plates below those of other sensitizers.

Keeping Tests.

In making the test on the relative keeping quality of plates sensitized by the two methods of bathing, a slow portrait plate which works fairly free from fog was used. A dozen of these were bathed by each method on a clear, dry day.

The water bathing was carried out as follows: The plates were placed in the case of a developing tank, washed in running tap water (temperature 18° C.) for five minutes, then transferred to a bath composed of tap water 1,900 ccs., pinacyanol stock solution (1 to 1,000) 38 ccs. After bathing for two minutes they were placed in alcohol for two minutes, swabbed off, and dried in a light-tight cabinet, through which air at room temperature was forced by an electric fan. When dry the plates were packed face to face in an ordinary plate box.

The other dozen plates were placed directly in a tank containing a bath composed of—

Water	1,300 parts.
Ethyl alcohol	700 ,,
Pinacyanol stock solution	40 ,,
Ammonia (28 per cent.)	40 ,,

After four and one-half minutes in this bath (18° C.) the plates were rinsed for two minutes in alcohol, swabbed off, and dried.

As soon as the two sets of plates were dry one of each was exposed in the sensitometer, and its filter factors were also measured. Another pair was treated in the same manner a few hours later on the same day. Then tests were made once a day for a few days and finally at intervals of about a week

The curves in fig. 2 show the variation in speed [9] to white light and the fog [10] of the plates sensitized by the two methods.

Fig. 3 shows the characteristic curves for a plate sensitized with pinacyanol, water, alcohol, and ammonia when the plate was usable, while fig. 4 shows the characteristic curves of a similar plate after it had become unfit for use.

The variation in speed through filters with time of keeping is shown in figs. 5 and 6. If these curves be compared with those for the variation in speed to white light (fig. 8), it will be seen that while the speed to white light was decreasing the speed due to the added sensitiveness conferred by the pinacyanol did not decrease at quite the same rate.

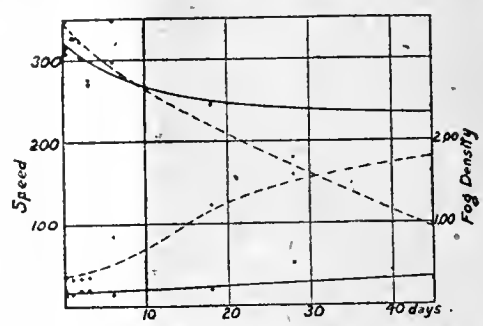

Fig. 2.—Keeping tests on plates sensitized with pinacyanol.
The curves which start at the upper left-hand corner of the graph show the speed to white light, while those that start at the lower left-hand corner show fog (for unit development to unit contrast) measured in density. Full lines: Plates sensitized with pinacyanol and water. Dotted lines: Plates sentitized with pinacyanol, water, alcohol and ammonia.

Note.—The fog is given for $\gamma=1$; that is, a development such that the contrast of the negative is the same as that of the subject.

Bathing Films.

In sensitizing films with pinacyanol it was found that the method of pre-washing and bathing in a water solution of the dye was not successful and that to get adequate sensitizing action it was necessary to use the bath containing water, alcohol, and ammonia. Films have a tendency to give more fog with bathing than do some plates. It has been remarked by some that any orthochromatic emulsion gives more fog when bathed than ordinary plates, and

7. Eder, Handbuch, 3, p. 86.
8. R. J. Wallace "Astrophys. Jour.," 26, p. 299; 1907.

9. "Speed" as used here is measured by the method of Hurter and Driffield. Briefly, this is as follows: When the density due to exposure to light is plotted against the logarithm of the time of exposure some of the points will lie on a straight line. If samples of the plate which have received a set of exposures are developed for different lengths of time, their respective straight line parts extended intersect nearly in a point on the exposure axis. The value of the exposure at this intersection point is called the "inertia" of the plate. The speed numbers used by us are 10 divided by the inertia, so that the greater the speed number the faster the plate. This number was selected instead of Hurter and Driffield's 34/I because the light source employed by them (the sperm candle) is deficient in the blue as compared with our light source, which approximates average noon sunlight in its distribution of spectral energy. It should be noticed that for this reason our speed numbers are not convertible into Hurter and Driffield numbers.

10. Fog is measured as density. Density is defined as $\log^{10}(1/T)$, where T (transmission) is the ratio of the transmitted to the incident light. Thus a fog density of 0.30 transmits one-half of the light falling on a plate; a density of 1.00, one-tenth of the incident light and a density of 2, one one-hundredth

suitable films for bathing are not obtainable except with some degree of orthochromatism. In bathing films it is necessary to

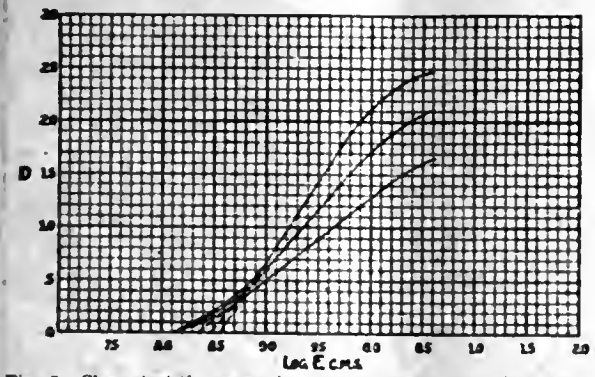

Fig. 3.—Characteristic curves for freshly bathed plate (pinacyanol, water, alcohol, and ammonia).

exercise considerable care that nothing comes in contact with either side of the film, since the back is usually coated with gelatine to

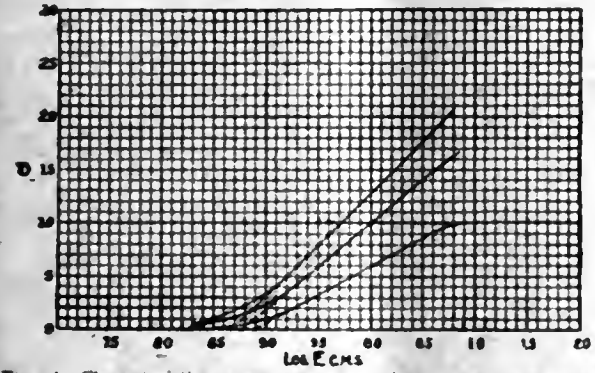

Fig. 4.—Characteristic curves for old bathed plates (pinacyanol, water, alcohol, and ammonia).

make the film non-curling. If the back of the film becomes scratched, these scratches will cause defects in the print.

FRANCIS M. WALTERS, JUNR.
RAYMOND DAVIS.

(To be continued.)

TWO-COLOUR EFFECTS ON DEVELOPMENT PRINTS BY SELENIUM TONING.

In the current issue of "Photographische Rundschau," Walter Forstmann describes the use which can be made of the single-solution selenium toner for producing two-colour effects in prints of a kind somewhat similar to those produced by local treatment of a print on self-toning paper with a solution of salt, but of greater range as regards colour. The process is based on the fact that a selenium-toned print is considerably altered in colour by treatment with a photographic reducing bath, such as the Farmer mixture of hypo and ferricyanide. By this method a print ranging in colour from purplish to warm brown may be obtained. The double tones which the process yields are very suitable for subjects such as evening effects, snowscapes, etc., since the contrasts in the original subject are reproduced, whilst, at the same time, a suggestion of the colouring is conveyed. By toning in the selenium bath for a greater or less time, the tones may be produced within fairly wide limits. On reduction, the details in the high-lights are not eaten away as is usually the case with the Farmer reducer, since the whole of the silver image has been converted into silver selenide. The latter is not attacked by potassium ferricyanide.

The well-washed prints may be toned in any suitable selenium bath without previous bleaching. Commercial baths vary as regards their suitability for different papers, some working best with gaslight papers and others with bromides. For purple tones the prints should be as fully developed as possible. In proportion as the colour of the developed and fixed print varies from black towards brownish or greenish, the warmer the purple tone which is finally obtained after reduction. Bromide prints, which (as is well known) tone with a lesser degree of readiness in the selenium bath, yield the same tones as gaslight prints after reduction, even if the selenium-toned image does not exhibit a distinct bluish or warm-black colour. For bromide prints it is well to use the selenium bath of about double strength. In the case of prints which have been developed as fully as possible, the time in the toning bath may be some minutes.

After a brief rinse, the prints are transferred to a 10 per cent. solution of potassium metabisulphite in order to clear the lights, and are then washed in running water for ten minutes. Without drying, the prints are then treated in the reducer. If they have been allowed to become previously dry, they must be thoroughly soaked in water before immersion in the reducer. The latter is the ordinary Farmer reducer, made up by adding a few drops of potass ferricyanide solution to hypo solution of from 5 to 10 per cent. strength. The mixture should be of pale yellow colour. It requires to be kept of about this strength (as judged by the colour) by addition of ferricyanide solution. After reduction the prints are finally washed for about half-an-hour.

The longer the time of toning in the selenium bath, the browner the tone which is produced, but it is to be noted that the prints become more purplish in colour on drying. Omission of the clearing bath between toning and reducing causes the whites to remain of pale yellowish colour; for many subjects this is by no means a disadvantage, the coloration in the high-lights improving the whole effect of the print. The following table shows at a glance the range of effects which can be obtained according to the kind of print and the degrees of toning and reduction:—

Development of black print	Time of toning	Time of reducing.	Colour of Finished Print.		
			Shadows.	Half-tones.	High-lights.
Full	Short*	Short	Black	Purple	Warm purple
Full	Long	Long	Purple	Warm purple	Brownish purple
Fairly full ..	Short	Short	Purple	Warm purple	Brownish purple
Fairly full ..	Long	Short	Warm purple	Brownish purple	Brown
Fairly full ..	Long	Long	Brownish purple to brown		
To greenish or brownish colour.	Long	Long	Warm brown to greyish brown		

* Barely perceptible toning.

It is to be noted that the contrast of the print is increased very slightly—to scarcely a perceptible extent. Any required reduction of the depth of the print must, therefore, be done before toning. It is not possible to give exact figures for the times of toning or reduction, since these depend greatly on the particular paper which is used and on the strength of the toning bath. A very little experience, however, will enable any particular tone to be obtained.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Latest date for entries, July 22. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15. Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.I. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for Entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

Photo-Mechanical Notes.

Contact Reproductions by Reflected Light.

In these notes of October 28, 1921, p. 645, particulars were given of the Mamil process of Max Ullmann, by which a result similar to that by the Vandyke process is obtainable from originals printed on both sides. A further specification, No. 156,691 of 1920, by Herr Ullmann adds something to the fragmentary working details which have been disclosed by the inventor.

It is pointed out that in the industrial use of the process according to Eng. Pat. No. 24,607 of 1913 (B.J. 1914, September 18, p. 714), the inconvenient experience has arisen that the water-soluble aniline dyes by means of which the chromate colloid coating remaining on the plate after the latter has been developed, is rendered opaque to light, become bleached out (that is to say, "bleeds") when left in water. Consequently the pictures lose their sharpness and have to be dyed again.

Further, it has been found rather difficult to apply aqueous preparations (e.g., a solution of gelatine) after drying the negative, without the risk of the coats taking up the dyes from the negative.

These drawbacks are obviated by converting the employed basic or acid dyes into water-insoluble coropounds.

It is known that basic and acid dyes are rendered water-insoluble by certain salts or acid or basic substances according to the character of the dye.

Thus, for instance, an aqueous solution of di-amido-stilbene-disulpho-acid diphenol yields a water-insoluble precipitate with dilute aqueous solutions of penta-methyl-*p*-rosaniline.

For example, in order to render the chromate colloid negative insoluble in and impervious to water, it is dyed in a dilute solution of penta-methyl-*p*-rosaniline, and then the dyed negative is bathed in a dilute aqueous solution of di-amido-stilbène-disulpho acid di-phenol. The result of these operations is that the water-insoluble dye-lake is formed in the chromate colloid coating, so that there is no running of the dye during the time that the negative is lying in the water, nor do warm gelatine solutions take up any dye if such are poured over the negative.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, June 26 to July 1 :—

CAMERAS.—No. 17,551. Photographic camera. A. Andriotis.

LENSES.—No. 17,908. Lenses for telescopes, cameras, etc. M. J. Gunn.

APPARATUS.—No. 17,673. Apparatus for automatically timing photographic exposures. Soc. Godefroy Frères.

CAMERAS.—No. 17,550. Photographic camera. A. Thomson.

VIEW-FINDERS.—No. 17,626. View-finders for photographic cameras. F. Southworth.

RETOUCHING.—No. 17,525. Apparatus for retouching photographs, etc. A. Bennett.

TRANSFER PROCESS.—No. 18,018. Method of transferring photographs on to fabric, paper, etc. A. Cohen.

PHOTOGRAPHIC MEDIUMS.—Nos. 17,851 and 17,852. Photographic mediums. F. W. Hochstetter.

COLOUR PHOTOGRAPHY.—No. 17,730. Process for production of transparencies for projection of photographs in natural colours. H. Diernhofer.

COLOUR CINEMATOGRAPHY.—No. 17,546. Colour projection apparatus for cinematographs. R. Killick and K. & S. Synd., Ltd.

COLOUR CINEMATOGRAPHY.—No. 17,791. Colour cinematography. R. F. E. Miller.

COLOUR MIXTURE.—No. 17,830. Device for admixture and control of light and colour for photography and photographic projection. M. J. Gunn.

COMPLETE SPECIFICATIONS ACCEPTED.

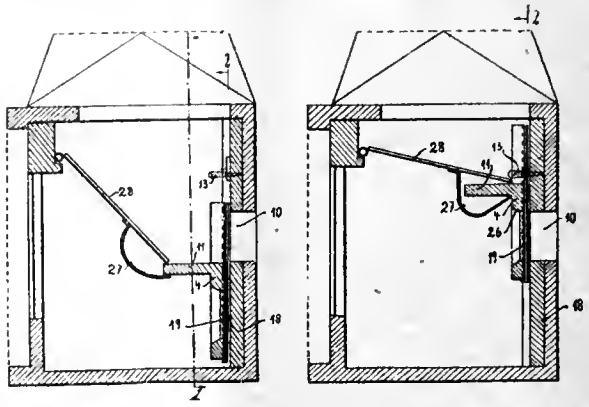
These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

NON-FOCAL-PLANE REFLEX CAMERA, No. 180,350 (November 19, 1920.)—The mirror 28 is directly connected with and controlled by a sliding piece 4 (moving behind the lens 10), which controls the duration of exposure.

A lateral support 11, on the sliding-piece 4, carries the one end of the mirror 28, and light-tight pocket 27 connecting the lateral support and the mirror in all positions of the latter.

The sliding-piece 4 is coupled with a shutter 19 by a spring, and both parts are controlled in such a manner that in the case of an instantaneous exposure the slide 4 and the shutter move successively without any hindrance from the set position through



the exposure position into the closed or end position, whilst in the case of a time-exposure the shutter is retained and the slide 4 moves alone from the finder position into the exposure position, in which it is retained until upon a new actuation of the apparatus the slide 4 is released and moves farther on to the end position, whilst the shutter 19 moves behind the slide at once from its first position through the exposure position on to the closed or end position.

The specification describes and illustrates other mechanism by which these movements are effected.—John Steenbergen, 65, Gottfried Keller Strasse, Dresden, Germany.

CINEMATOGRAPH PROJECTION LENSES.—No. 180,949. (September 3, 1921.) The invention relates to objectives used for cinematograph projection, and its aim is to secure a better and more uniform illumination of the projection screen than is possible with present types of projection lenses. With this lens the illumination of the screen falls off less rapidly from the centre to the edge of the screen than is usual.

The improved illumination of the projection screen is achieved by a novel constructional modification of the well-known Petzval portrait lens, in which modification the ratio of the back focal length of the objective to its equivalent focal length is not greater than .35. In the common proportions of the Petzval portrait lens the ratio of the back focal length to the equivalent focal length usually exceeds .5 : in the example quoted by Von Rohr, page 250 of his "Theorie u. Geschichte der Photographischen Objective" this ratio is .58.

In a projection objective consisting of two separated components, we call the component which is the nearer to the object in cinematograph projection the back component, and the component which is the nearer to the projected image we call the front component. By the term "back focal length" we mean the focussing distance of an object behind the back component when the projected image is infinitely distant.

The amount of light transmitted by an objective from any point on the object to the corresponding point of the image is proportional to the solid angle subtended at the object-point by the entrance pupil of the objective. The novel proportions adopted for an objective according to the invention have for aim, therefore, to throw the entrance pupil of the objective

nearer to the object so that a greater quantity of light is passed to the screen for imaging purposes in the peripheral parts of the field than is passed by a lens of ordinary type working at the same aperture.

In the usual type of Petzval portrait objective now on the market, the ratio of the back focal length to the E.F.L. is generally higher than .5, and the entrance pupil, when the objective is used for cinematograph projection, is between the front component and the projected image; whereas in the new construction the entrance pupil is nearer to the object, lying on the other side of the objective, somewhat further from the objective than the object, a better position when, as often happens in cinematograph projection, the object is small compared with the focal length of the objective.

The new construction is illustrated by a numerical example below and by fig. 1. R, R_1, etc., denote the radii of the surfaces proceeding from the front to the back, i.e., in the direction opposite to that in which light travels when

Fig. 1.

the objective is used for cinematograph projection, and the + sign denotes that a radius receives this light on its concave side, and a − sign that it receives light on its convex side. The glass material is defined by the values of the symbols n_D and v, both of which we use in the conventional sense, and by the type number in Chance's optical glass catalogue. The lens thicknesses are denoted by T, T_1, etc., counting from front to back, and the separation of the two components by S. All the dimensions are in inches. This objective is illustrated by fig. 1 of the drawings.

E.F.L. 10″. Back focal length 2.508″ (fig. 1).

—Arthur Warmisham and Kapella, Ltd., both of 102, Stoughton Street, Leicester.

Dry-mounting.—No. 179,826 (May 11, 1921).—Aluminium plates are substituted for zinc or other plates. By the use of aluminium plates a considerable reduction in the time expended in the process is effected, as heat from the press is uniformly distributed throughout the aluminium plate at a much quicker rate.

The plates are preferably provided with tube or handles of non-conducting material to facilitate the manipulation of them when hot.—Joseph Henry Stean, 6, Highbury New Park, London, N.5.

Viscose Sensitive Films.—No. 179,500. (January 26, 1921).—The claim is for the process for the manufacture of a sensitive viscose or similar cellulose film with a carrier permeable to water, which consists in providing the carrier with a sensitive emulsion in such way that the concentration of the sensitive salt is effected on one surface only, by thoroughly moistening the carrier in water, removing the surplus water, subsequently coating the still wet carrier with a photographic emulsion having a gelatine base, uniformly distributing the coating and thereupon coagulating the emulsion in the usual manner.—Jaques Edwin Brandenberger, 16, Rue du Louvre, Paris.

Viscose Sensitive Films.—No. 179,250 (January 26, 1921). The raw viscose support is passed through the first sensitising bath, which serves to cause the film to swell up and to impregnate it with one of the products intended to react subsequently. After this, and before passing the film through the second bath, it is doubled; that is to say, two films are laid one against the other, and passed, for example, between pressing rollers. Thus a double film is obtained which is then submitted to the action of the final bath with the object of forming the sensitive salt in the interior of the film. After this operation the two films previously stuck together are separated and thus two films are obtained in which the sensitive salt is found to be concentrated on a single surface.—Jaques Edwin Brandenberger, 16 Rue du Louvre, Paris.

The following complete specifications are open to public inspection before acceptance :—

Apparatus.—No. 182,117. Photographic apparatus. W. Fenerzeug.

Lenses.—No. 182,106. Endless series of lenses destined for a cinematograph, affording optical compensation of the travelling of the image. Firm of C. Zeiss.

Paper Films.—No. 182,085. Manufacture of paper films. V. Kriegerbeck and J. Bautz.

Cinematography.—No. 182,087. Cinematographic apparatus. V. Kriegerbeck and J. Bautz.

Trade Names and Marks.

REGISTRATIONS RENEWED.

Autochromes Lumière.—No. 306,657. Union Photographique Industrielle Etablissements Lumière and Jougla Réunis. Registered in 1908 in class 1.

Perfecta.—No. 301,933. Thornton-Pickard Manufacturing Co., Ltd. Registered in 1908 in class 8.

Wellington 'Xtra Speedy (Label).—No. 305,462. Wellington & Ward. Registered in 1908 in class 1.

TRADE MARKS REMOVED FROM REGISTER.

In the official language of the "Trade Marks Journal" the following trade marks have been "removed from the register through non-payment of renewal fees." Such non-payment is of course the method adopted by a firm having no further occasion for the use of a mark.

Vesca.—No. 299,018. London Stereoscopic and Photographic Co., Ltd. Registered in 1907 in class 8.

Electroid.—No. 301,374 A. W. Penrose & Co., Ltd. Registered in 1908 in class 11

P.P.A. Congress Exhibition.—The following have consented to act as judges at the photographic exhibition to be held in connection with the Congress of the Professional Photographers' Association, Ltd., on September 11-15, at the Princes Galleries, Piccadilly, S.W.1:—The Right Hon. the Earl of Carnarvon, Mr. Pirie MacDonald, Mr. Furley Lewis, Mr. J. B. B. Wellington, and Mr. H. W. Bennett. Silver and bronze medals will be placed at the disposal of the judges for awards.

Photographische Korrespondenz.—In consequence of the economic conditions in Austria, the Vienna Photographic Society has suspended the regular publication of "Photographische Korrespondenz" during the present year, and has published a special issue, a "Festnummer," which celebrates the sixtieth anniversary of the foundation of the Society. This issue contains a large number of contributions by photographic writers and experimentalists on the Continent, and includes some papers of special interest, to which we have already drawn attention. The "Festnummer" is published by the Vienna Photographic Society, 25, Westbahnstrasse, Vienna VII. In Austria its price is 1,500 kronen; for other countries, with the exception of Germany, the price is 10 Swiss francs.

New Books.

BROMOIL PRINTS AND BROMOIL TRANSFERS.—A welcome *résumé* of recent methods in Bromoil printing is provided by No. 186 of the "Photo-Miniature" just published. Within the pages of a very practical monograph have been brought together the experience and formulæ of a large number of Bromoil workers in this country and America, among them Raymond E. Crowther, S. Grimshaw, G. Bellamy Clifton, A. C. Barfield, Dr. A. D. Chaffee and W. H. Zerbe. Recommendations of suitable bromide papers and of bleach formulæ are here in sufficient abundance to satisfy the habitually experimental mind of the Bromoil enthusiast, whilst the less experienced in the method will derive considerable aid from the detailed instructions in pigmenting. The transfer Bromoil process is the subject of a special chapter, in which a few hints are given, and, we are glad to see, some strong cautions uttered, regarding the making of multicolour Bromoils by transfer. Altogether the issue of our little contemporary is a timely addition to the literature of the Bromoil process. It is illustrated by reproductions of Bromoils by pictorialists in the United States, which scarcely do justice to the qualities of the process. Published in this country by Messrs. Houghtons, Ltd., 88-89, High Holborn, London, W.C., price, 1s. 8d.; in the United States by Tennant & Ward, 103, Park Avenue, New York, price 40 cents.

New Apparatus.

The Salex 3½ by 2½ in. Reflex. Sold by the City Sale and Exchange, 54, Lime Strect, London, E.C.3.

APPROPRIATELY to our note of last week on the convenience of the reflex camera in the 3½ x 2½ in. size, comes a camera of this size and pattern which the City Sale and Exchange have just introduced, complete with 4¼-in. *f*/4.5 anastigmat lens, at the moderate price of £10 17s. 6d. The camera is built for taking pictures the

"landscape" way of the plate, and has the lens in a focussing mount. Its overall dimensions are approximately 5¼ x 5 x 5 ins., and its weight about 2 lbs. The focal-plane shutter obtains a full range of speeds by alteration in the width of the slit combined with tension of the spring. The mirror is of the hand-raised pattern, and the hood, which is kept in place when folded by a pair of leather flaps, is 5½ ins. in height when erected. There is flexible metallic release of the shutter, and the price of the camera includes three single metal dark-slides, film pack adapter, and leather sling shoulder strap, together with a back focussing screen and hood. A bush for the tripod screw is provided in the base of the camera, so that it can be used in the ordinary way with the mirror in the up position, a lever on the outside of the camera holding the mirror up, as required when making time exposures.

New Materials.

PLASTIC WOOD.—This mouldable material, which hardens on exposure to the air into a tough, solid waterproof substance, is a new manufacture of Messrs. Necol Industrial Collodions, Ltd., 62, London Wall, London, E.C.2. It is a thick paste, or rather dough, having an odour of ether, which quickly sets into a solid, hard mass, yet allows of sufficient time for its use in stopping holes in woodwork. No doubt the material will find useful applications in minor repairs to cameras or other photographic apparatus of wood. It is supplied in tins at the price of about 2s. 6d. per pound.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 15.

Bradford Photo. Soc. Outing—Fountains Abbey.
Edge Hill C.C. Outing—Blundellsands and District.

MONDAY, JULY 17.

Royal Phot. Soc. "The Amateur Photographer and Photography" Prize Competition Prints.
Southampton C.C. Demonstrationettes.

TUESDAY, JULY 18.

Hackney Phot. Soc. Desensitol. J. Jevans. Barnet Matt Plates. W. Selfe.
Bournemouth C.C. Outing—Golf Links and Talbot Woods.

WEDNESDAY, JULY 19.

Rochdale Amateur Phot. Soc. "Satista" Demonstration. A. E. Cooper.
Bournemouth Camera Club. Outing to Isle of Wight.

THURSDAY, JULY 20.

Sheffield P.S. Outing to Grenoside.
Hackney Phot. Soc. Outing to Stanwell-in-the-Moor.

CROYDON CAMERA CLUB.

Mr. L. J. Hibbert gave a practical demonstration on "The Making of Colour-Screen Plates." He started to the sound of corks popping, perhaps the cheeriest sound in Nature, which outside was making good with a wind-driven temperance deluge.

Many will remember the old Thames plate, capable of really good results (at intervals), with which he was associated on the technical side. Two members of the club, Mr. John Keane and Mr. S. J. Tayler, employed the plates largely in night photography to illustrate a lecture given by them at a Convention meeting held at Exeter some years ago, and favourable opinions were expressed at the rendering of the colours photographed under artificial illumination.

One gathered from what Mr. Hibbert said that the financial side was the primary cause of the disappearance of the forerunner of the Paget plate. If the Autochrome be any criterion, on which one hundred hands were engaged for seven years before it saw the light of day, preliminary research and experimenting must be prolonged and necessarily very costly. He paid a high tribute to the work of Messrs. Lumière. The Autochrome plate was indeed a wonderful achievement, and possessed the advantage of giving a direct colour positive by simple chemical procedure. Also, correction had never been sacrificed to speed.

Whirlers, micrometer registering frames, and other appliances actually used in the making of the Thames plate (the first one on the market with a regular screen formation, the Joly screen excepted) were then shown in operation, and the method of manufacture clearly explained. A hearty vote of thanks was accorded Mr. Hibbert for an evening full of interest.

News and Notes.

PHOTOGRAPHIC CONVENTION.—At the annual general meeting, held at Shrewsbury last week, it was resolved to hold next year's meeting of the Convention at York.

BURGLARS' NEW IDEA.—At Clacton-on-Sea last week burglars broke into a cinema and stripped the operating machines of their lensers and condensers. Loss and damage are estimated at £250.

"CAMERA HOUSE JOURNAL," Messrs. Butcher's trade house organ, gives in its July issue particulars of new goods, including a series of developers put up in bottles which are stamped with ½-oz. markings.

XL PHOTOGRAPHIC SUPPLY, 238, Railton Road, Herne Hill, London, S.E.24, send us some excellent specimens of their work in black and sepia postcard printing. They make a specialty of prompt dispatch, and their price is the same for black, sepia and vignetted prints.

CITY SALE AND EXCHANGE.—A 68-page list from the branch at 54, Lime Street, London, E.C.3, is specially assigned almost exclusively to professional apparatus, and lists an immense number of field and studio cameras, anastigmat, rectilinear and portrait lenses, and a considerable variety of shutters. Obtainable free on application.

MESSRS. Ross, LTD., have recently opened a branch establishment at 100, Deansgate, Manchester, under the management of Mr. A. S. Havart, hitherto the firm's outside representative in London. Mr. Havart will be pleased to place his knowledge of the various Ross manufactures at the disposal of dealers and others in Lancashire and the North.

HOUGHTONS' PROFESSIONAL BULLETIN.—In the July issue Mr. Alexander Mackie conveys some lessons on the legal relations between a photographer and his customer in a vein of fiction. Messrs. Houghtons' write in a strain of optimism as regards improvement in trade and the disappearance of German competition, and the commercial notes announce a further reduction in the price of plate-sunk mounts.

MESSRS. CAMPBELL-GRAY, LTD., inform us that they have been appointed the sole official photographers to the British Empire Exhibition, from this date until the opening, and during the run of the Exhibition in 1924. The concession is to include the taking of all and any kinds of photograph in the Exhibition, selling of such photographs, and the selling of photographic apparatus, materials and appliances.

PHOTOGRAPHY BY THE SEA.—Messrs. W. Butcher and Sons, Camera House, Farringdon Avenue, London, E.C.4, are issuing to dealers, at the price of 2s. 6d. per 100, an attractive booklet on the opportunities of seaside photography, written by Mr W. L. F. Wastell, whose personal and photographic qualifications are summed up in the description "expert photographic humorist." It is emphatically a booklet for the dealer's counter during the next few weeks.

PROFESSIONAL PHOTOGRAPHIC PRINTING ASSOCIATION.—In sending us their price list for bromide enlargements and contact prints and other descriptions of work for professional photographers, this firm mentions that the principal, Mr. John Done, is probably the oldest photographic printer in active work, having begun his connection with the trade by employment with Elliott & Fry in 1865, and having been engaged as a trade printer from 1871. The price list may be obtained free on application to 115, Queen's Road, Bayswater, London, W.2.

CAMERAS AT FOLKESTONE.—Cameras are more numerous than ever at all seaside and health resorts this year, even though the true holiday season has not yet started. A correspondent who is visiting Folkestone states that during a bright morning last week he took a walk along the Leas eastward to the Harbour Pier, returning by way of the beach and the new zig-zag path, when he counted 131 cameras, being carried or in use. As far as could be ascertained, the patterns of the cameras seen were:—Folding film, 62; box-form film, 27; folding plate (including film pack), 10; box-form magazine, 10; reflex, 8; and miscellaneous, 14. There were three film users to every plate user. As the Folkestone season is not yet at its height, it may be assumed that the numbers given above may very soon be trebled.

NORTH YORKSHIRE AND SOUTH DURHAM PROFESSIONAL PHOTOGRAPHERS' SOCIETY.—The third meeting was held at Mr. Sidney H. Wood's Studio, Darlington, on July 4. The Society is now firmly established, and includes among its members all the well-known photographers of the district. After the business was disposed of, light refreshments were provided, and then Mr. Wood conducted the members round the several departments of his business, and explained his methods of working. Mr. Wood also gave a demonstration with several pieces of his apparatus, which included the most up-to-date appliances. This was thoroughly enjoyed by the members, and a very hearty vote of thanks was accorded Mr. Wood for a most interesting and pleasant meeting. The hon. secretary is Mr. Albert E. Ba[illegible], Bishop Street, Stockton-on-Tees.

Commercial & Legal Intelligence.

NEW COMPANIES.

INTERCHANGEABLE LENS CO., LTD.—This private company was registered on June 30 with a capital of £3,500 in £1 shares. Objects: To carry on the business of wholesale opticians, lens makers and edgers, manufacturers of and dealers in machinery, tools, engines and plant required for use in connection therewith, etc., in any part of the world. The permanent directors are:—E. A. Archer, Mapleton, Forfis Green, N.2, optician; H. L. Taylor, Fernleigh, Station Road, Solihull, Warwick, optician; A. E. Symons, 320, St. John Street, E.C.1, C.E.; C. B. Ustonson, 47, Hazelwood Lane, Palmers Green, N.13, optician. Qualification, 50 shares. Registered office: 10, Clifford's Inn, Fleet Street, E.C.

C. ROBINSON CENTRAL PHARMACY, LTD.—This private company was registered on July 1 with a capital of £300 in £1 shares. Objects: To acquire from C. Robinson the business carried on as The Central Pharmacy at Aire Street, Knottingley, and to carry on the business of chemists, druggists, stationers, opticians, dealers in photographic goods, etc. The first directors are:—W. E. Milburn, Hill Top, Knottingley, chemist and druggist; C. Robinson, Hazelmere, Park Avenue, Castleford, drug-store proprietor; Mrs. L. Robinson, Hazelmere, Park Avenue, Castleford. Qualification, one share.

LEADLAY, LTD.—This private company was registered on July 1 with a capital of £2,000 in £1 shares. Objects: To carry on the business of advertising specialists and publicity agents, advertising contractors and agents, designers, blockmakers, engravers, photographers, photographic printers, photo-lithographers, printers and publishers, etc. The first directors are:—E. O. Leadlay, 55, Ashburnham Mansions, Chelsea, S.W., advertising specialist; F. P. Walker, 15, Ellsworthy Terrace, N.W.3, organ builder. Registered office: 61, Berners Street, W.1.

VIEW POSTCARDS.

To the Editors.

Gentlemen, I should like to endorse most of what Mr. Tardrew says in his letter to you, published in the "B. J." of the 7th inst. British photographers have, I fear, let the picture postcard trade slip through their fingers, and it is now too late to recover it or to make the publication of view-postcards a profitable undertaking. A considerable amount of apathy has been shown by the local worker, with the result that the big firms have stepped in and captured the cream of the trade.

There has been a lack of enterprise on the part of local workers, and not 5 per cent of the postcards now being sold at popular seaside resorts are from negatives made by local photographers. A visit to three South Coast towns only last week opened my eyes as to the present state of the view postcard trade. The sales of

the 9d.-per-dozen variety are brisk enough, but they are of little or no interest to the photographer, the cards being by one of the photo-mechanical processes. "Real photograph" cards such as the local worker would produce are not in demand, their cost being too high. Although of fairly good quality, the subjects pictured on the cheaper cards leave much to be desired, and many are out of date; their antiquity, however, does not spoil their sales, the average tripper not being a good judge of quality.

Many years ago—sixteen to be accurate—I visited one of the Continental establishments producing postcards, when I saw thousands of postcards being printed, cut up, and despatched to England, and I then realised how useless it was for a British professional to attempt competition with the large Continental firms, who at frequent intervals send their own operators to our shores or purchase negatives from our own countrymen, in order to keep their sets up to date.

To play about with the view-postcard or to run it as a side line means loss of money, time, and temper, more especially at the popular holiday resorts, where the shops are already overstocked and cards are being offered at cut prices. In Folkestone, for instance, I saw the same cards in three streets being sold at 8½d., 9d., and 10½d. per dozen, or 1d. each if purchased singly.—Yours faithfully,

G. J. HENDERSON.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. N.—"Treatise on Practical Light," by Dr. R. S. Clay, 563 pages, Macmillan, 12s. 6d. net, is, we think, quite the best book of the kind you require. It describes a lot of experiments with very simple apparatus.

W. H. S.—If the hypo and metabisulphite are of proper quality there is no reason why the plates should not fix quickly. The only explanation we can think of is that plates were exposed to white light before fixing. Some plates are rather susceptible to this; that is to say, do not fix rapidly if exposed to white light before going into the fixing bath.

B. Y.—We believe the 5-portrait studies are taken with a set of three mirrors. So far as we know there are no particulars published of how to arrange the mirrors; that is a matter of trial according to the circumstances. The Tress Co. used to supply sets of mirrors for these portraits, and no doubt if you wrote to their successors, Eveling and Tress, Ltd., 4a, Rathbone Place, Oxford Street, London, W.1, they would be able to supply you.

P. J.—We are afraid there are no purchasers of photographic relics. We think the best thing you could do would be to present the negatives to some institution which would take care of them and keep them for the use and interest of photographers. For example, the Liverpool Amateur Photographic Association, 11, Dale Street, Liverpool, or the Royal Photographic Society, 35, Russell Square, London, W.C.1, both of whom have a museum in which many objects of historical interest in photography are preserved.

H. L.—(1) Most rapid plates have a tendency to be somewhat coarse-grained, but in none should it show in the print. We should advise you to use isochromatic plates, to give full exposure, and to develop with a rather weak developer. We should imagine that your eyes suffer from astigmatism, in which case you should have them tested by a good optician and proper glasses fitted. (2) Approximately grainless negatives can only be made on very slow plates, but most of the best portrait work is now done with plates of 400 to 500 H. & D.

NEWSPAPER.—Your letter heading does not bear your address, so that we cannot reply to you by letter. An average fee is 10s. 6d. per subject, but you do not appear to be aware that you have no rights whatever in the photographs, since they were taken to the order of your customer, and therefore the latter is the owner of the sole copyright. If your customer likes, he can take action against the newspaper for infringement of his copyright, and also would have good ground for proceedings against yourself, if not as regards copyright, at any rate, as regards breach of implied contract.

C. G.—About the best stop bath for bromide prints is a very weak solution of acetic acid, about 1 dram of acid in 30 ozs. of water. As this is a weak bath, plenty of it should be used, as the acid becomes continuously neutralised by the alkali passing into the bath with the prints. At the same time it is best not to use a stronger bath. We ourselves think there is very little object in using a stop bath at all. It is a mistake, we think, to develop prints in such a way that they have to be snatched out of the developer and its action suddenly stopped in order to prevent it from going further. Much better to give such an exposure that the prints will practically not develop too dark, however long they are left in the developer.

E. B.—It is not necessary to have the sheets, which you use for reflecting and diffusing the light, very long; 2 ft. should be enough. As a substitute for the expensive reflectors you might make D-shaped reflectors of card, with thin nainsook or madapolam fronts. If you take a six-sheet imperial board, 31 x 21, and bend it so that the edges are 17 in. apart, securing them with string or wire at top and bottom, and then sew the fabric to the edges so that you have a flat front 21 high and 17 wide, you will find it answer every purpose. You must keep the lamp quite central to avoid scorching. If you are satisfied with the results you could have the apparatus made of tin at a small cost. We have used a set of six such lanterns for six months, and only had one card slightly scorched. You can suspend them from the "flex" with strong string.

C. S.—It is not possible to form any opinion of the cause of the fog, particularly in the absence of any of the negatives. You seem to think that the fogging may be due to a particular conjunction of slit width and lens aperture, but we do not think that there is anything in these variations which has anything to do with the cause of the fog. If the fog is caused in the camera, the edges of the plate which are covered by the rebate of the dark-slide ought to be practically clear glass. If this is so, then the cause is most probably to be sought in the lens or camera. The former may be suffering from a species of flare, which causes general veil, or the camera may have parts in it which scatter light on to the plate. It is almost impossible even to guess at the cause without examining the camera. If the whole plate, including the edges, is fogged, then the cause is probably in the development, not necessarily the dark-room illumination, which from what you say appears to be all right, but perhaps a faulty composition of the developer or impure chemicals.

JOURNAL OF PHOTOGRAPHY.

No. 3246. Vol. LXIX. FRIDAY, JULY 21, 1922. Price Fourpence.

Contents.

SUMMARY

The paper by F. M. Walters, jun., and R. Davis, giving the results of a study of colour-sensitising plates by bathing, deals with the use of dicyanine and the orthochromatising sensitisers, and also with the hypersensitising of commercial panchromatic plates. There is a note on the increase of speed by washing before exposure, and the authors describe in detail the procedure and method of drying to be followed in colour-sensitising by bathing. (P. 430.)

Mr. A. Lockett describes a modification of Mr. W. E. Debenham's method of measuring focal length, which takes account of the (small) error due to neglect of the nodal space. (P. 434.)

In a note on toning with tin salts, Mr. J. G. F. Druce describes experiments to show what takes place when a bleached print is toned with an alkaline tin solution. (P. 433.)

M. L. P. Clerc describes some new apparatus which has recently come upon the French market, and refers to the very pleasing work with semi-corrected lenses recently shown in Paris by Commandant Puyo. (P. 427.)

In a leading article we deal with the opportunities for effective portraiture which present themselves in ordinary rooms, and may be well utilised provided that the possibilities are realised in comparison with those of an ordinary studio. (P. 426.)

In a contributed article, Mr. H. J. Comley urges a more progressive spirit among photographers—for example, in the utilisation of the most recently available methods of negative-making and printing. (P. 428.)

Mr. E. A. Dench gives a description of a number of window displays used by dealers in the United States and Canada for attracting business in the development and printing of amateurs' films. (P. 429.)

A person who carries on a business in a name other than his own is required to register that business, even although it is a branch of a business in the same town which is carried on under the person's own name. Such, at any rate, is our interpretation of the Business Names Act. (P. 425.)

Opportunities for commercial photography to the order of collectors, etc., may often be found even in towns which have not the industrial demand for this kind of work. (P. 426.)

The Professional Photographers' Association has begun the publication of its monthly "P.P.A. Record." (P. 425.)

The term "matt" in reference to printing papers includes several distinctive surfaces, some of which are ideal for small portraits. (P. 426.)

Still another process for the dye-toning of transparencies has been patented—by a German firm. The silver image is bleached with quinone, first used and patented for this purpose by MM. Lumière. (P. 426.)

An automatic film camera for aerial photography is the subject of a recent patent specification. (P. 436).

EX CATHEDRA.

The P.P.A. Record.

It is, perhaps, natural that the Professional Photographers' Association should feel the need of an organ which should allow it to address its members fully regarding the movements which are taking place within the Association, and also should deal with certain matters exclusively from the standpoint of the professional photographer. The first issue of the "P.P.A. Record," which has been established with these aims, as we understand them, has at length made its appearance. Its pages afford ample evidence of the sincerity and energy with which leading members of the Association are devoting themselves to the affairs of that body and, in particular, to the arrangements for the Congress which, in September next, will celebrate the twenty-first birthday of the Association. Possibly, domestic concerns will occupy a smaller proportion of space when the "Record" has got fairly into its stride. As a journal seeking to influence professional photography as a whole, it necessarily must consider those who are without as well as those who are within the P.P.A. We are confident that its object is to exercise a thoroughly healthy influence, and therefore we wish it every success. If any criticism is to be expressed of this first number, it concerns chiefly the indecision of the typographical setting. There are too many kinds and sizes of type. The "Record" should surely offer to its readers a better example of tasteful printing.

* * *

Registration of Business Names.

A question which has recently been put to us by a correspondent in reference to the application of the Registration of Business Names Act no doubt arises in other cases, and may, therefore, be noticed here. Our correspondent carries on a business under his own name, and is establishing another which he intends to carry on under a name not his own. He asks whether it is necessary for him to register the latter business. Although the Act does not specifically refer to such a case as this, we think that undoubtedly registration of the second business is required. The object of the Act is to disclose to the public the real names of the people with whom they are dealing in entering into transactions with any business firm, and the fact that a particular business is a branch of another (the ownership of which is published) does not conceivably afford any ground for exemption of the former from the provisions of the Act. Inasmuch as it is not uncommon for a photographer to have two businesses in a town, one under his own name and another, of a cheaper character, under a fancy name, it is well that the requirement of the Act in this respect should be borne in mind. While we are referring to the Act, it may be mentioned that the offices of the Registrar of businesses in England and Wales has recently been removed from Russell Square, to 3 and 4, Clement's Inn,

London, W.C.2. The Edinburgh office is still at Exchequer Chambers, Parliament Square, and the Registrar of Irish businesses is still, presumably, to be found at Coleraine House, Dublin. Forms of application for registration may be obtained from these addresses.

* * *

The Surface of Small Prints. When albumen was the only surface for photographic prints the photographer had little opportunity for going astray in his choice, the only difference being between single- and double-coated papers. The great variety of surfaces now available in bromide and gaslight papers, while rendering it easy for the thoughtful worker to select one suitable to the work on hand, may lead another less careful to use a totally unsuitable surface, because it is ready to his hand. Really, glossy surfaces are not now admitted in good class portrait work, but there is a wide range to select from before a heavy dead matt surface is reached; and in choosing a surface it must be remembered that it is the size of the face and not the area of the print which has to be considered. There are now many grades of paper which are just not dead matt, ranging from ivory to satin, and these will be found very serviceable for single full lengths or small groups. The surface of some of the "matt" self-toning collodion papers is as near the ideal for small work as can be imagined. There is no gloss, yet there is no suspicion of blocking up in the shadows.

* * *

Quinone Dye-Toning. The Aktiengesellschaft für Anilin Fabrikation has added its name to the long list of those who have taken out patents for processes of dye-toning, and in so doing have utilised the observation, originally made by MM. Lumière, that a silver image is partially bleached by a solution of quinone, the gelatine, at the same time, being definitely hardened. Their process, according to the abridged particulars of the patent specification, No. 180,292 (which is open to inspection before acceptance), consists in treating a print for ten minutes with a solution of benzoquinone or naphthoquinone, mixed with potassium chloride or bromide. The print is briefly washed and then immersed in a solution of safranine and acetic acid, after which it is cleared with sodium bisulphite. The silver compound formed by the quinone bleaching solution may be removed as in other dye-toning processes. It would certainly seem that the mordanting of a dye upon a silver image which has been bleached with a solution of quinone is a fresh contribution to the knowledge of dye-toning. Nevertheless, it is difficult to see in what way the process as a whole can avoid the patent granted to MM. Lumière for the use of quinone in conjunction with bromide as a toning preparation. On the other hand, the latter's British patent, No. 25,751 of 1910, has now probably not long to run before its expiry.

* * *

Commercial Work. Not every photographer is alive to the importance of commercial work. This class of work has often to be sought out, and a well-worded circular, directed to the proper quarters, may bring in considerable business. The scope of the business will depend on the locality, and in the absence of manufactures there may be dealers in the fine-arts and books who are constantly wanting photographs for advertising or sale purposes. Also, and this may prove the most remunerative source, there are amateurs and collectors who can easily be persuaded to have their treasures photographed. It would be an easy thing for a photographer to find out who are the dillettanti in the neighbourhood who collect first editions, Chelsea ware, or Charles II. silver. Professional musicians, and some of the best amateurs, are likely to possess an old violin or 'cello of value. Study of the local newspapers, attendance at local concerts, bazaars, etc., will provide much of this information, or even friendly communication may be made with the dealers. The circular might point out to the collector the advisibility of a record of valuable objects, the danger of destruction, and so on; to the dealer, the commercial advantages of a photograph of every object of value which passes through his hands, to be kept with the record of purchase and sale, etc., will appeal. When dealing with a business man, a frankly commercial attitude on the part of the photographer, with a strict system of costing, should be adopted.

THE POSSIBILITIES OF ORDINARY ROOMS.

THERE is an evergrowing tendency to dispense, for various reasons, with the orthodox glass-roofed studio for portraiture, and to endeavour to make the best of premises which are otherwise desirable, but which have no top light. This was done in the early Daguerreotype days, and with the enormous increase in plate speeds, the problem of lighting should not be a serious one, if the photographer is willing to limit his poses to those which can be successfully handled under such conditions.

The very poor results which are often produced, even by skilled studio portraitists, when working in an ordinary room, are probably due to the photographer starting on his work with a settled conviction that the place is unsuitable and that nothing approaching a studio portrait can be obtained in such confined quarters. This is a great error, as many successful workers have proved. If Rembrandt had disdained the lighting given by the narrow windows of his father's mill, the artistic world would have lost the grandest lessons in concentrated lighting which have ever been given. The moral to be deduced is obvious; it is to work on the lines of least resistance, that is to say, to make use of such effects as are naturally produced, and to avoid straining after effects which can only be obtained in an open light.

The work that has been done with a concentrated artificial light should point the way to the use of a single window. When it is remembered what Van der Weyde did first, and hundreds have done since, with a four-foot umbrella-shaped reflector, fitted at first with a single pair of carbons, why should we look askance at a window six feet high and four broad illuminated with God's daylight? It is true that the reflector is movable and the window is fixed in its position, but we still have two factors, the sitter and the camera which can be moved at will.

It is a great mistake to think that much longer exposures are needed when working with a small source of light. This leads many to be afraid of controlling such a light, thus obtaining an over-lighted effect, which would not be so easily produced with the broader lighting and more generous space of the usual studio. The fact is that when a sitter is placed near an ordinary unscreened window, the light is far too strong, hence the chalky half-black-half-white faces which are so often seen.

As a rule, the ordinary window gives too low a light. As the glass extends to about thirty inches from the floor, there is a lack of shadow beneath the brows, nose and lower lip, and the eye nearest to it is suffused with light. This is easily overcome by fixing a shutter or dark curtain so that no light is admitted below four and a half feet from the floor. If the light be dull the upper

part may be left unscreened, but in a bright light a thin muslin curtain should be drawn across it. Provided that the top of the window be not less than seven feet from the floor, the conditions are now entirely favourable for everything but standing figures, which cannot be essayed with any reasonable hope of success. There is little practical utility in giving specific instructions for placing the sitter and the camera to produce certain effects. The first lesson the portraitist has to learn is to use his eyes; failing this power, volumes of instruction are useless.

The reflector plays an important part in the class of work under discussion, for as all the light is emanating from one source, reflected light must be largely employed to give shadow detail. For this reason the walls of the room should be light in colour, and not of a red or yellowish tint. A light grey is the most suitable; white or the very palest grey is chosen for the movable reflector.

Due consideration must be given to the size of the camera and the focal length of the lens, these being dependent upon the working space available. In a small room a large camera and lens will seriously curtail the opportunities for obtaining a variety of poses.

If full length, standing, poses have to be taken, unless the room be unusually lofty, say, eleven or twelve feet to top of window, artificial lighting must be resorted to, and in the majority of cases half-watt lamps will be found the most convenient. They may be used in conjunction with daylight or alone. If used to supplement daylight, a couple of 1,500 c.p. bulbs, fixed near the ceiling in a line with the edge of the window which is nearest the camera, will do all that is needed, but, if to be used alone, at least six 1,000 c.p. bulbs will be needed with facilities for raising and lowering them. When it is to be used independently, a more advantageous position than that indicated may be found. Very often a room only 12 or 14 feet wide at the window side extends back 18 or 20 feet, and it is then desirable to make use of the greater length.

A small background frame, say, 6 feet 6 inches by 4 feet, fixed upon brackets with castors, will add greatly to the ease of working. On one side, a medium grey plain ground may be stretched, and a light grey or white upon the other. A very dark curtain, suspended from a rod at the top of the frame, will complete the outfit.

As it will often be necessary to work with the lens pointing towards the light, an efficient hood should be fitted to the camera. A very good form is a wire frame fixed to the top of the camera and projecting about a foot beyond the lens; upon this, dark curtains are fixed at the top and sides, the latter being arranged so as to draw round in front until only such light as will reach the plate will pass. This will greatly help, too, in the production of bright negatives.

PARIS NOTES.

Photographic Processes.

I was interested in obtaining evidence recently of the success which has followed the advocacy by some of the French photographic journals of the more extended use of orthochromatic methods among both professionals and amateurs. In conversation with M. E. Grieshaber, the technical head of the "As de Trèfle" plate-making firm, I learnt that the proportion of orthochromatic plates made in his works is now 50 per cent. of the total as compared with 5 per cent. ten years ago. He recorded also a much wider use of anti-halation plates and did not doubt that his experience was also that of other manufacturers.

In a former note ("B.J.," May 19, 1922, p. 294) I referred to the process of M. F. Monpillard for the extra-sensitising, as regards both general and colour sensitiveness, of emulsions by bathing. The first trials which have been made of this method have shown that it is not the easiest to work. It seems that failures are due to the fact that the silver chloride, or its solution in ammonia, may have been exposed for a short time to light.

M. Louis Lumière has recently published an ingenious method of washing negatives, permitting of this process being carried out in a very short time and with a minimum consumption of water. A fluid ounce of water is sufficient for washing a quarter-plate in 12 to 16 minutes. The process is as follows:—Upon a board, which is placed almost upright, there is fixed a sheet of glass and then a length of absorbent cotton fabric, the upper part of which dips into a small vessel filled with water, whilst the lower part communicates with any receptacle. Under the influence of capillary attraction the strip of fabric forms a kind of siphon, which slowly discharges the contents of the upper vessel into the lower. By laying the negative face down on this fabric, there is a constant passage of the water through the gelatine and a rapid removal of the soluble salts. It is advisable that the negative should be previously treated in an alum bath in order to prevent the texture of the fabric from impressing itself upon the surface of the negative.

Some sensitometric tests have recently been made in the laboratory of the Estienne Municipal School (connected with the book industry) by L. P. Clerc. They show that with wet-collodion plates the reciprocity law may be considered as holding good. Attempts made to determine the value of the Schwarzschild exponent showed that this latter may be considered as practically equal to 1.

Some New Introductions.

German cameras have again appeared in the French market, where they are frequently offered as second-hand, as a means of disguising their recent importation. Several new firms in the manufacture of cameras, particularly the Gallus Usines, the Noxa Company and the firm of Baille-Lemaire are combating this competition with considerable courage and have afforded evidence of their manufacture of many cameras of excellent design and construction at very moderate prices.

A print-drying machine of the endless web pattern, but of smaller size, has been produced in France for the French Kodak Company from the design of the manager of the firm's finishing department, M. Jelinsek the original inventor of machines of this kind. In the present model the lengths of fabric successively envelop two heated cylinders, the temperature of the second being greater than that of the first. The band of fabric moves round the second cylinder in a direction opposite to that in which it moves round the first. One of the first of these machines has been acquired by the Aviation Service and will be officially shown in the international exhibition of aerial photography, which is to be held at Brussels from June 23 to July 9 under the auspices of the Aero Club of Belgium. The machines have been supplied to Kodak, Ltd., London, so that a full description is unnecessary.

At the Paris Fair a Parisian instrument maker, M. E. Piquet, showed a quartz "boiler" for the rapid electrical heating of liquids. It consists of a tube of quartz curved in the shape of an elongated horseshoe and forming an electric resistance. Simply by immersing it in the liquid to be heated, the latter may be brought practically to boiling without danger of in-

juring the "boiler" or contaminating the liquid. The accessory is one which will be extremely convenient in the preparation of solutions and particularly for bringing working baths to the required temperature.

Half-watt lamps, overrun or run at their proper voltage during the actual exposure, have made considerable strides among portrait studios, and two types of equipment have recently been presented to the studio of the French Photographic Society and tested there with success. These are the Philipps Photoclar lamp and a ceiling lamp with vertical diffusion introduced by the firm of Leacap.

The Puyo Exhibition.

Since the war we have been far from being surfeited in Paris with exhibitions of pictorial photography, and thus the collection of works by Commandant C. Puyo, which has been arranged by the French Photographic Society, has met with great success, as did also the meeting at which this well-known artist discoursed upon the prints shown on the walls. In addition to examples of the gum-bichromate process, the collection includes oil prints, both direct and transfer. M. Puyo is of course well known as the pioneer in the use of anachromatic lenses for pictorial work, and he went to a good deal of trouble in classifying his prints in order to show the particular description of lens employed in making the negatives. Among the most interesting of these simple objectives is a plano-convex lens, the curved surface of which faces the subject, a diaphram of f/7 being placed behind. It serves excellently for large heads, and if turned the other way about gives somewhat inferior definition but then covers a wider field more evenly and is useful for head and shoulders portraits. A symmetrical objective consisting of two single meniscus lenses, working at f/5, is suitable for somewhat out of focus portraiture at its full aperture, and at f/7 gives more critical definition, which was well displayed in some photographs of interior subjects. In landscape work, in order to get sufficient depth of focus M. Puyo is of opinion that, whatever the focal length of the lens, the diaphram should not be larger than one inch diameter. His best results were obtained with the lens recommended by De Pulligny as the "adjustable landscape lens," consisting of two glasses, the front one plano-convex and the rear one plano-concave, both of 4 in. focal length and having their flat surfaces facing one another. In portraiture his best results had been obtained with a telephoto which he fitted up for himself by using any negative lens behind a Petzval portrait lens. He preferred to use a camera having a mid-way lens board or frame on which the negative lens could be mounted, whilst the positive portrait lens was attached to the usual lens front.

Without exception, in the use of these anachromatic lenses, it is necessary to bring the plate slightly nearer to the lens after having focussed in order to compensate for the difference between the visual and chemical rays. The amount of this shift may be ascertained once and for all for each lens and as a rule is 1-400th. of the camera extension.

L. P. Clerc.

EFFICIENCY IN PROFESSIONAL PHOTOGRAPHY.

Of late years much has appeared both in the daily Press and in various technical journals dealing with the need for higher efficiency and improved methods of production in every important industry. No industry, whether high or low in the scale of national importance, can afford to neglect the employment of means which may be calculated to increase its value as an industry and the value of its particular productions in the commercial world. Photography is certainly not now among the least important of our national industries. Its value for naval and military purposes became so increasingly obvious during the late war that it is difficult now to realise how it would be possible to conduct a successful campaign without the aid of a camera. Its employment is recognised in various departments of important industries, such as railways, shipbuilding yards, engineering works, printing offices, etc., many of which now have their own photographic department and staff; to say nothing of the great world of advertising, and the exceedingly important part which it plays in the reproduction of illustrations in books, magazines, and newspapers. This evidence alone must satisfy the most contentious critic that photography has already established itself in an unassailable position in our national commercial life, and that it is impossible to set limits to the opportunities which are still presented to it, or to calculate the sum of the value to which it is capable of attaining This being admitted, it is clear that workers in this important industry should aim at the highest efficiency of which they are capable, not only that they may enjoy a congenial and lucrative employment, but that, by their efforts, they may assist in continuing the advancement of which we have been the contemporaries.

Photographers as a class have never been too eager to take up fresh methods and new ideas. Generally speaking, new ideas have brought with them their own workers as well as their own exploiters and capital. The older hands have been content to jog along in their old time-worn rut, and to leave to others the pleasure and profit of the newer and more refreshing pastures. How persistently the photographer of twenty to thirty years ago refused to have anything to do with the amateur trade, and so allowed this lucrative business to fall into the hands of the chemists, who reaped the rich harvest which photographers should have enjoyed. If we come to the consideration of more recent opportunities, we find the same negative spirit in the manner in which the professional photographer has neglected cinematography and colour photography. Granted that the latter has not yet arrived at a stage when simplicity of manipulation or uniformity of successful results upon paper has made it a particularly attractive proposition for professional exploitation; still, the fact must not be overlooked that a few courageous enthusiasts have made it a profitable department of their businesses, and it is probable that a greater demand for materials for colour work would have encouraged manufacturers to still greater efforts. A serious study of the art of colour reproduction, or even of the more simple processes of correct colour rendering in monochrome, would give many an old photographer a new interest in life, and a new zest for the craft in which he now foolishly thinks there is nothing more for him to learn. Real life is ever an onward progress; we either progress or decay, and if we would get the most out of the life we live, to enjoy it fully, we must taste of its new joys and bear its new burdens; we must embrace opportunities as they present themselves.

Then again, it would surprise anyone who took the trouble to ascertain facts how very few professional photographers have any real practical experience in the use of panchromatic plates and the various light-filters with which these plates may be used for the rendering of colour in monochrome. Many have dabbled in panchromatic work, but comparatively few, apart from those who are exclusively engaged in commercial photography, have become its enthusiastic votaries and made it a regular feature in their businesses. The writer has had it remarked to him by one of our leading portraitists, "I am too busy making money with the plates I am familiar with to bother about taking on new methods of doing the same thing," an expression which may

be regarded as typically British in its sentiment, but none the less to be deprecated and deplored by all who have the future development of photography at heart. So many are only too eager to take all they can get out of photography but are unwilling to make an effort to put anything into it in return, in order that others may gather some of the fruits of their experience. How manifestly unfair it is to keep assistants working at obsolete methods and with out-of-date materials, and not to allow them to have the opportunity for making progress in their craft. Every pupil or apprentice has the right to expect that he will receive instruction in all the most modern methods and processes; and an important clause in his agreement should be that he would be given the opportunity to thoroughly master the theory and practice of panchromatic work. The assistant of the immediate future will be seriously handicapped in his advancement if he has not this training implanted and well rooted within him. The assistants of the writer for the past sixteen years have had the greatest possible encouragement to familiarise themselves with this work both for printing in monochrome and tricolour, and all of them would, I believe, endorse the opinions now being expressed. I have no desire to overestimate the importance of the use of panchromatic plates, but I submit that no one can lay a just claim to being an expert operator to-day unless he has had practical experience in panchromatic work. I am fully aware that any change to new processes or methods of manipulation is regarded as somewhat revolutionary, and therefore objectionable in an old-established business, but in the many new businesses which have opened up since the war, and also in the many older businesses which have changed hands in recent years, there can be no such excuse for continuing in the old worn paths simply because they are familiar and well trodden, but every valid reason why one should expect to find in these businesses the evidence of reconstruction upon up-to-date lines. You owe it to yourselves, to your assistants, and none the less to your patrons, that each and all of you should benefit by the constant progress which is being made in photographic methods. Let the rising generation of photographic craftsmen be craftsmen indeed, and not merely commercial exploiters; let them aim at making photography a craft to be looked up to with respect, and with which any man may be proud to be associated. This will only be done by assiduous effort on the part of those who love their work for the work's sake, and who really have the future of photography at heart.

HENRY J. COMLEY.

GETTING MORE PRINTING AND DEVELOPING WORK.

SERVICE and good work are the two things that count in photographic developing and printing. These two things should form the subject matter for attractive window displays, whether you do the work yourself or send it out. Some American examples along these lines are given below :—

Sam Schwartz, Newark, N.J., U.S.A., employed window strips to convey the following messages : —

"Do we develop? YES."

"Films? We have them."

The Big League Sporting Goods Co., New York City, stimulated business over a stated period by a special offer. The woman purchasing the largest amount of cameras and supplies, and having the most printing and developing done, by May 29, was presented with a large fur-clad kewpie doll. This offer was given considerable window card publicity. Each card bore the following reminder : "Get Busy Girls." The kewpie doll formed the central window exhibit.

Meeker's, Danbury, Conn., had a very attractive window card, which bore the sketch of a puppy pulling the film out of a camera. The card was captioned :—

"Developing and Printing for Amateurs."

The National Drug Co., Chicago, Ill., went after the business of office workers with the window card as below :—

"Leave your films to be developed on your way to business.
They will be ready when you go home."

Cunningham's, Detroit, Mich., conveyed the difference between printing work done by them and by another local concern. A large card at the front of the window was divided into two parts. Fastened to the top half of the card were several discoloured prints, with the caption above."

"There's a difference. Prints which have been improperly fixed. Note the discoloration."

The lower half of the cards contained a number of perfect prints, with the caption :—

"Below are prints made in our finishing laboratory a year ago. Note they are in the same condition as when first made. No discoloration. We give professional service."

Another display by Cunningham's, Detroit, Mich., contained a varied assortment of rolls and packs of film. The goods were exhibited on large glass stands. Attention to the display was called by a large cardboard arrow at the rear centre. The wording on the arrow was as follows :—

"Even if your size camera is not made any more, we have films for it."

Coy's, Wheeling, Ohio, even secure printing and developing work after store hours. They do this by means of a cabinet in the doorway, equipped with envelopes and a cavity for depositing one's work. The patron fills in the necessary particulars on one of the envelopes, places his film pack or rolls inside, and deposits them in the slot.

The Owl Drug Co., Portland, Ore., devoted a display to cameras and supplies, backed up by a large card containing several rows of numbers. The card stated that :—

"These are the LUCKY NUMBERS for this week. Get yours." The contest which extended for one month only, entitled the lucky customer to a free enlargement. One out of every fourteen orders was singled out in this manner. Each receipt for printing and enlarging was marked with a number, and those who held receipts with the numbers drawn received the free enlargements.

Cill's, Portland, Ore., have individualised their photographic department by a character creation called "Photo Phil," the body of which is pictured as a film roll, with short arms, legs and head. For window display purposes, this character creation was recently reproduced as a life size cut-out. One arm was raised, and this held a large piece of black cardboard with the caption at the top in red :—

"A Message for You."

An arrow underlined the words and pointed to a sheet of paper pasted on the cardboard beneath the arrow. The announcement, written on the firm's letter-head, was as follows :—

"DEAR KODAKERS,

"I have some good news for you! Each week, until October fifteenth, I will select the best negative out of those brought to me, make an attractive enlargement, and put it in the window Saturday, where it will remain over Sunday. After this, the prints and enlargements will be a gift from me to the photographer.

"At the end of the period stated, the best of the pictures exhibited in this way will receive a No. 3 Ansco Autographic camera!

"The only limitation to this contest is that the picture must be DEVELOPED and PRINTED by me.

"Hoping that this contest will inspire clearer and finer pictures,

"Cordially yours,

"PHOTO PHIL."

The figure of Photo Phil was made with a red body, green legs, flesh-coloured arms and hands. A blue velvet drape ran from the

figure to a stand, on which was a tripod camera. This, as a card proclaimed, was the "Grand Prize." At the left was a two-foot enlargement, fastened to a card, "Winner for this week."

The North Western Photo Supply Co., Seattle, Wash., covered the window floor with brown plush, with a large vase filled with fruit blossoms at the left side. Spread out on the floor were several playing cards, all hearts, with appropriate descriptions written on them. The first card, the ace of hearts, was entitled: "Your Kodak." The next card, the king of hearts, stood for "Eastman Film." The queen of hearts was "Our finishing department," while the Jack stood for "Art proof enlargement." The remaining card—the ten-spot of hearts—called attention to "Hand colonring by our artist." Behind the cards was the sign which proclaimed "An Unbeatable Hand."

Wakelee's Pharmacy, San Francisco, Calif., had a window display to emphasise their prompt developing and printing service. In the middle of the show, surrounded by cameras and supplies, was a cardboard clock dial, with arrows pointing to the hours between nine and five. Underneath the dial was the following sign :—

"EIGHT HOUR SERVICE.

"A cent a minute discount will be allowed customers for each minute, after eight hours, for delivery of films and prints."

E. A. DENCH.

STUDIES IN COLOUR-SENSITIZING BY BATHING.

[A scientific paper, No. 422, recently published by the Bureau of Standards, Washington, is that entitled "Studies in Colour-Sensitive Photographic Plates and Methods of Sensitizing by Bathing," by Francis M. Walters, junr., and Raymond Davis. As will be seen from its somewhat abridged text, which we reprint, it contains the results of numerous trials respecting the best method of using pinacynol and other colour sensitizers, *e.g.*, dicyanine, pinaverdol, pinachrome, orthochrome T. and homocol. It also deals with the increase of speed in panchromatic plates by washing before exposure.]

(*Continued from page* 419.)

Speed of Plates Before and After Bathing.

To study the camparative sensitizing action on plates having different characteristics as to speed and contrast, four plates made by the same manufacturer were selected, a fast plate, a medium-speed plate, a slow plate, and a process plate. The plates were

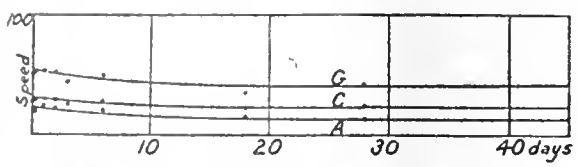

Fig. 5. Plates sensitized with pinacyanol and water.

sensitized in a bath containing pinacyanol, water, alcohol, and ammonia Table 1 shows the results obtained:

TABLE I.

Plate.	Initial speed.	Speed after bathing.	Speed with filters. A.	B.	C	G.
Seed 30 ..	500	315	26	29	28	66
Seed 26x ..	400	300	28	27	25	69
Seed 23 ..	180	135	19	17	21	47
Seed process..	31	29	6	4	2	10

These results indicate that more added sensitiveness is conferred by the dye bath on slow plates than on fast ones. It may be concluded that when speed is not the factor of prime importance,

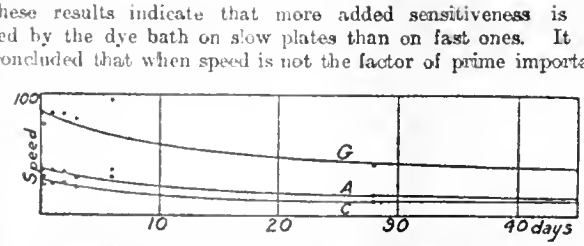

Fig. 6.—Plates sensitized with pinacyanol, water, alcohol, and ammonia. The *G* filter gives very nearly the added sensitiveness due to the dye. The *A* filter shows the red sensitiveness. The *C* filter shows the blue sensitiveness. If these curves be compared with those in Fig. 8, it will be observed that the colour sensitiveness does not decrease as rapidty with time as the sensitiveness to white light.

the plate chosen for bathing should be selected on the basis of its freedom from fog, its developing characteristics (contrast), and its resolving power.

Spectrograms show that the sensitiveness added by pinacyanol is about the same for the 30, 26×, and 23, although the blue sensitiveness which the plates had originally still falls in the same order as the speed before bathing. Relatively the process plate has acquired a much greater sensitiveness than the other three plates, although its actual speed is far below them.

It may be remarked here that the blue sensitiveness of a plate is decreased by sensitizing. Thus the plates which were used for the keeping test had before bathing a speed of 55 with the C filter (blue), while after sensitizing with pinacyanol and water the speed dropped to 23, and after sensitizing with pinacyanol, water, alcohol, and ammonia to 26.

Dicyanine.

The makers' instructions for the use of dicyanine call for much the same procedure as in the case of pinacyanol. However, with dicyanine, even pre-washing failed to give satisfactory sensitizing with the water bath. Mees[11] states that it is necessary to bathe the plates immediately after adding the stock solution of dicysnine to the water, but even this procedure failed to give satisfactory results with the specimen of dye employed. This sample of dicyanine was about three years old.

When this sample of dicyanine was used with ammonia in the presence of enough alcohol to prevent flocculation, the sensitizing action was satisfactory. The use of ammonia has the important advantage of extending the sensitiveness to longer wave lengths, as well as increasing the action of the dye at its maxima. It is due to the use of ammonia that certain investigators[12] have been able to photograph in the infra-red as far as 1,000μ, while those who have not used ammonia with dicyanine have failed to photograph further than 800μ.

A satisfactory bath for dicyanine is as follows:—

Water	60 parts.
Ethyl alcohol (95 per cent.)	40 ,,
Dicyanine stock solution (1 to 1,000)	4 ,,
Ammonia (28 per cent.)	4 ,,

The more ammonia used the greater the sensitizing action, but the proportion of ammonia is limited by the fog it induces.

Dicyanine requires more care in its use than the other photo-sensitizing dyes. The solid dicyanine should be bronze green in colour. If it is not, particularly if it appears brownish, the dye has deteriorated and should not be used. The dye must be kept cool and dry in order to retain its sensitizing power. A freshly mixed bath of dicyanine is a bright blue-green colour. As soon as the dye deteriorates the colour changes considerably, the solution appears dull, and, in addition, shows a transmission band in the red. Such a solution should not be used. The temperature of the bath should not exceed 18° C. if plates reasonably free from fog are to be obtained. The alcohol rinse after bathing is decidedly beneficial.

11. Mees and Wratten, "Photographic Jour.," 58, p. 25, 1908 (Newton and Butl).
12. B. S. Bull., 14, p. 376, 1917.

Orthochromatic Sensitizers.

The other important sensitizers investigated were pinaverdol, pinachrome, homocol, orthochrome T, and erythrosine. These dyes are by no means as sensitive as pinacyanol and dicyanine to the action of electrolytes; they do not flocculate so readily in the presence of ammonia, potassium bromide, and alum. With the orthochromatic sensitizers the action of ammonia is most marked with erythrosine and homocol. The other dyes show a slight increase in sensitizing action with ammonia, but hardly enough to justify its use.

Erythrosine.

Erythrosine is stated by Eder[13] to be the best of the fluorescein dyes for sensitizing. Other important representatives of this class are eosine and rose bengal. He also states that plates bathed with erythrosine are superior to plates in which the dye is incorporated in the emulsion. We were not able, however, with the sample of erythrosines used (Kahlbaum) to produce plates which were as sensitive in the yellow-green as the orthochromatic plates made by one American manufacturer.

We found erythrosine to give the best results when used according to the directions given by Eder.[14] The plate is given a pre-bath for two minutes in

Water	100 parts.
Ammonia	2 ,,

Then it is bathed for two or three minutes in a bath of

Water	100 parts.
Stock solution (1 to 1,000)	20 ,,
Ammonia	2 ,,

The bathed plates should be washed in water to remove the excess dye from the gelatine. A rinse in alcohol will shorten the time required for drying.

An inspection of the spectrograms of commercial orthochromatic plates indicates that erythrosine or a dye of the erythrosine type is used in their manufacture. The advantage of erythrosine over such dyes as pinaverdol is its limited region of sensitizing action, since the sensitiveness conferred by erythrosine ceases abruptly at 580μ while the action of the other dyes continues rather farther into the red. This limited region of sensitiveness makes it possible to develop plates made sensitive with erythrosine in the light of an ordinarily good red dark-room lamp. This is a decided advantage to the practical photographer. One of the reasons that panchromatic plates have not been more generally used is that they must be developed in total, or at best in slightly modified darkness, so that the photographer is unable to judge whether or not he is carrying development to the contrast required by the subject and the printing medium to be used.

Pinaverdol, Pinachrome, Orthochrome T, and Homocol.

These dyes are very much alike in the regions for which they sensitize. Of these four dyes, homocol has its sensitizing action increased most by the use of ammonia. Their greatest application probably lies in their use in conjunction with pinacyanol to supply the slight deficiency of the latter in the green.

Hypersensitizing Commercial Panchromatic Plates.

The well-known action of a bath of dilute ammonia in increasing the speed of an ordinary dry plate was applied to commercial panchromatic plates in the process worked out by S. M. Burka[15] and C. C. Kiess at this Bureau in 1918. They found that commercial panchromatic plates bathed for four minutes in—

Water	75 parts.
Ethyl alcohol (95 per cent.)	25 ,,
Ammonia (20 per cent.)	3. 5 ,,

had the total speed increased 100 per cent. and the red speed increased 200 to 800 per cent. A greater increase in speed was obtained by the use of 3.5 to 100 cm. of water, with the omission of the alcohol. In this case, however, the plates dry more slowly and develop *more* fog than when alcohol is included in the hypersensitizing bath. A rinse in alcohol after the ammonia bath will help in drying the plates more rapidly. In an early investigation of the sensitizing properties of cyanine Schumann found that bathing in a dilute solution of ammonia imparted great speed and sensitivity to a plate with cyanine incorporated in the emulsion. (See "Photographische Rundschau, 3, pp. 143, 175; 1889.)

In fig. 7 are shown the results of a keeping test made on Wratten Panchromatic Process, D. C. The plates were hypersensitized without the use of alcohol. The plates gave evidence of a slight increase in speed for a few days after hypersensitizing,

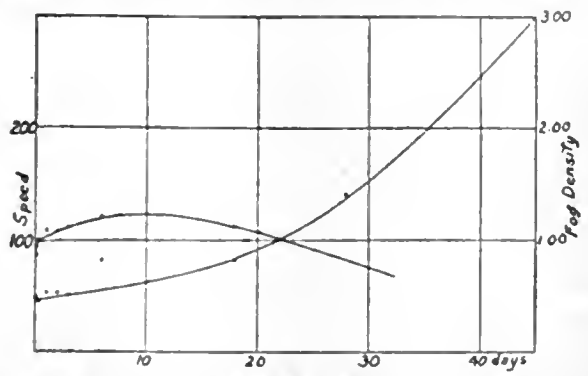

Fig. 7.—Variation of Speed and fog with time of keeping hypersensitized plates.

The fog has increased from a density of 0.45 to 3.00 in 45 days (a density of 3.00 transmits 1 1000 of the incident light).

Note.—The fog is given for $\gamma 2$; that is, the development was carried until the contrast was twice that in the subject.

while the fog kept increasing from the time the plates were hypersensitized.

A comparison of the increase in speed brought about by washing and by hypersensitizing commercial panchromatic plates shows that a part of the hypersensitizing action is due to the removal of certain soluble restraining substances by washing. In Table 2 are given the results of washing and hypersensitizing three typical panchromatic plates.

Increase in Speed by Washing before Exposure.

The improvement in sensitizing by washing the ordinary plate before bathing in pinacyanol-water solution suggested that there might be a corresponding improvement in the speed of commercial panchromatic plates. Accordingly a few typical panchromatic plates were washed for five minutes in running tap water and dried, following which the total speed to white light and the filter factors were measured. As seen from Table 2, all of the panchromatic plates showed decided improvement on being washed.

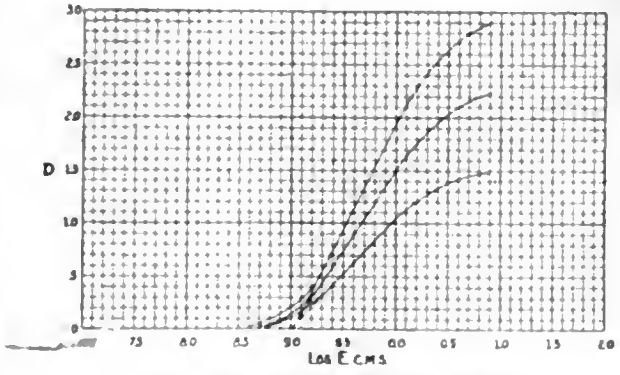

Fig. 8.—Spectrum process plate, untreated.

That the effect is not due to a change in the rate of development is clear from an inspection of figs. 8 and 9, which show the characteristic curves for the spectrum process plate before and after washing. Nor is the improvement due to the sensitizing action of some impurity contained in the tap water, since plates washed in a few changes of distilled water showed the effect as well if not better than with tap water. That the action is not due to a variation of the water content of the plate may be concluded from the fact that the plates before exposure in the sensitometer were backed and allowed to dry for about an hour. This time is sufficient for the unwashed plate taken from the box to come to the same state of humidity as the plate which had been washed.

This increase of sensitiveness may then be concluded to result

13. Eder, Handbuch 3, p. 174.
14. Eder, Handbuch, 3, p. 176.
15. Jour. Frank. Inst., 189, p. 25., 1920.

from the removal of certain restraining substances from the emulsion. From our experience with pinacyanol, chrome alum, and potassium bromide suggest themselves as the restraining substances.

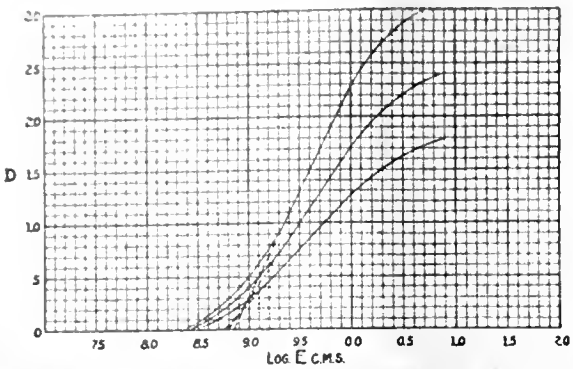

Fig. 9.—Spectrum process plate, washed in tap water for five minutes.

The comparison of the spectrograms of unwashed and washed panchromatic plates (fig. 10) shows that the greater part of the increase in speed to white light comes in the region of sensitiveness, which is due to the dyes. This is borne out by the speed measurements with the filters.

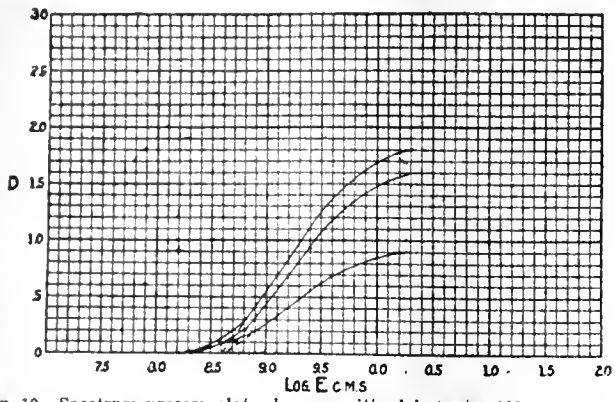

Fig. 10.—Spectrum process plate, hypersensitized in water 100 cc., ammonia (20 per cent.) 3.5 cc., and bathed four minutes.

TABLE II.

Plate.	Treatment.	Total speed.	Speed with filters.				Fog density for $\gamma=1$
			A	B	C	G	
Spectrum process *a*	None	96	5	8	8	16	0.40
	Washed ..	155	13	19	11	40	0.40
	Hypersensitized	235	22	34	16	75	1.30
Wratten panchromatic D.C.	None	180	16	15	17	36	0.20
	Washed ..	240	32	26	19	80	0.40
	Hypersensitised	380	59	50	44	140	0.50
Pan-ortho ..	None	91	9	7	8	16	0.30
	Washed ..	145	25	15	10	45	0.40
	Hypersensitized	275	49	32	19	106	1.30

a The spectrum process and the pan-ortho plates were over a year old, while the Wratten plate had just been received from the factory.

The table shows that while washing does not bring the increase in speed that hypersensitizing does it does not cause the production of as much fog. The characteristic curves (fig. 8, 9, 10) show that washing improves the scale or rendering power of the plate, while hypersensitizing does the reverse.

Manufacturers are urged to investigate the increase of sensitiveness found by washing in water, as it may be of considerable advantage to so treat their panchromatic plates before placing them on the market.

The Technique of Plate Bathing.

More or less difficulty will be experienced by anyone learning to bathe plates. It is advisable for the beginner to carry out the process in full light. This will enable him to follow the process and to discover the effect of the different baths on the plate; whether or not the bathing is sufficiently long for the dye to get through the emulsion, and whether or not the rinse removes the dye well enough from the gelatine. It will tell him how much he has to rock the trays containing the baths and will give him some idea of how long it takes the plate to dry after bathing.

An essential of successful sensitizing is absolute cleanliness. Dust or particles of old dye baths remaining in the trays will cause spots and streaks. Glass trays are to be preferred to enamelled trays because of the smoother surface and the less likelihood of contamination.

Foggy plates may be due to a number of causes—the choice of the wrong brand of plates for sensitizing, stray light during bathing and drying, the use of baths at too high a temperature, slow drying, or too much ammonia in the dye bath.

Slow drying sometimes gives rise to areas of varying sensitiveness on the plate, depending upon which part of the plate dries first. The rate of drying may be increased by the use of the alcohol rinse and by the use of a properly designed drying cabinet.

The drying cabinet shown in fig. 11 has several advantages. The air driven in at the top by an electric fan passes through efficient light traps, both at the top and the bottom. Two doors form the front of the box, and opening them gives access to all of the shelves, of which there are four, to hold drying racks filled with plates. The upright form of the cabinet gives it a very large capacity for the amount of floor space required. The long distance the air has to travel gives uniform distribution of the air current to all parts of the box in which plates may be placed.

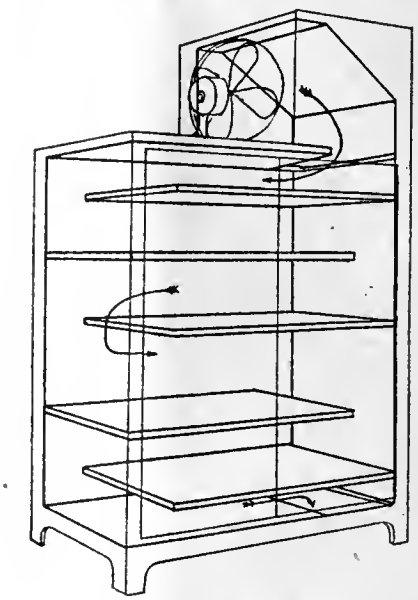

Fig. 11.—Drying cabinet.
The outside of the cabinet is shown in light line and the inside in heavy line.

Procedure and Formulas.

1. Stock solutions. —Stock solutions are usually made with pure ethyl alcohol (90 per cent. or stronger.) Some dyes are water soluble (erythrosine), while others dissolve in methyl alcohol. The usual strength is 1 g. of dye to 1,000 ccs. of alcohol (or in the same proportion). Some dyes are less soluble than this and require from 2,000 to 10,000 ccs. of alcohol to dissolve 1 g. of dye. It is advisable to put the dye in the solvent instead of pouring the solvent on the dye, as some of the dye may stick to the bottom of the bottle and require considerably more shaking to get into solution. If the dye does not dissolve in cold alcohol, the bottle containing the dye may be placed in a water bath and heated until the alcohol boils. If it does not go into solution after boiling 30 minutes, more alcohol should be tried.

2. Water solutions.—The bath is composed of

Water	100 parts.
Stock solution	2-6 ,,

Pinacyanol.—Wash the plate five minutes before bathing. Bathe two minutes. Rinse in alcohol until the film feels hard (three to five minutes).

Pinaverdol, Pinachrome, Orthochrome T.—Pre-wash optional. If pre-wash is omitted, bathe for four minutes.

Homocol.—Pre-wash optional, bathe four minutes if omitted. For increased sensitizing action, add 2 cc of ammonia.

3. Water, alcohol, and ammonia solutions. To be used when water dye bath flocculates on adding ammonia.

Water	65 parts.
Ethyl alcohol (95 per cent.)	35 ,,
Stock solution	2-4 ,,
Ammonia (twenty-eight)	2-4 ,,

In mixing this bath allow the alcohol and water to cool after mixing, add the stock solution, stir well, and then add the ammonia. Some baths work better if the minimum amount of ammonia is added before bathing the first plate, and more ammonia added as the bath loses its ammonia.

The plates are put directly in this bath, care being taken that the bath covers the entire plate. Bathe for four or five minutes and rinse in alcohol until the film is hard. Temperature should be 18° C. or less.

Pinacyanol.—As directed.

Dicyanine.—Requires full amount of ammonia.

Summary.

An investigation of the methods of sensitizing ordinary plates by bathing shows that certain precautions are necessary with some of the modern photosensitizing dyes and not with others.

Dicyanine gives a much greater sensitiveness and extends farther into the infra-red when used in a dilute alcoholic solution with ammonia than when used with water alone.

Pinacyanol gives good results in dilute alcoholic solution with ammonia, but plates bathed in water and stock solution are almost as sensitive and keep much better, provided the plates are thoroughly washed before sensitizing, as the soluble salts contained in the emulsion prevent the sensitizing action by flocculating the dye.

Washing has a favourable action on the colour sensitiveness of panchromatic plates and, while not so marked as the action of dilute ammonia, it gives no increase in fog, which always follows the use of ammonia.

The modern orthochromatic sensitizers, pinachrome, pinaverdol, homocol, and orthochrome T, are much less sensitive to electrolytes than are pinacyanol and dicyanine. Ammonia may be added to a staining bath of water and stock solution only, but does not increase the sensitizing action appreciably except in the case of homocol.

Films are best sensitized in a bath containing water, alcohol, ammonia, and stock solution.

Certain brands of orthochromatic plates were found to be superior to plates bathed with erythrosine (Kahlbaum's), but no panchromatic plate compared favourably with pinacyanol bathed plates, except one experimental emulsion furnished by an American manufacturer.

FRANCIS M. WALTERS, JUNR.
RAYMOND DAVIS.

TONING WITH TIN SALTS.

ABOUT a year ago, in the course of some chemical researches upon the organic compounds of tin involving the use of alkaline stannite solutions, it was observed that when these stannite solutions were warmed a change occurred causing the deposition of a grey precipitate. On examination, this precipitate was found to be metallic tin. The reaction which took place when a solution of sodium hydrogen stannite, for instance, was heated may be represented by the equation :—

$$2NaHSnO_2 = Na_2O_2 + Sn + H_2O.$$

Thus sodium stannate should be produced at the same time. On testing the alkaline filtrate after removing the metal this was found to be the case.

Since sodium hydrogen stannite, made by treating stannous chloride with excess of caustic soda solution, is also a strong reducing agent, it was at once thought that this deposition of a finely divided tin precipitate might be of service in various toning processes, and extensive investigations have been carried out both with the view of producing pleasant tones on bromide prints and with the object of elucidating the nature of the chemical reactions which take place in these processes.

The appearance of a fairly exhaustive article on "Colloid Silver Toning with Tin Salts," by Dr. F. Formstecher, in *Photographische Rundschau*, 1921, 58, page 277—an excellent account of which appeared in the *B.J.* for December 23, 1921, pp. 759-761—tempted the present writer to discontinue these investigations. But, as the subject is of considerable theoretical importance and adds something to the results obtained by Dr. Formstecher and also by Miss Woolley and Mr. Gamble, described in the *B.J.*, 1913, December 26, pp. 987-991, since quantitative experiments have been made, it is considered of sufficient importance and interest to place on record the results that have been obtained.

From the pictorial viewpoint pleasing tones can undoubtedly be produced by toning with stannous compounds, but there is some difficulty in obtaining uniform results, and ordinary sulphide toning is much simpler to carry out and gives uniform and certain results. Nevertheless, tin toning merits consideration.

For toning the bromide prints were first bleached with the ferricyanide solution recommended in the *B. J. Almanac* for 1922, p. 483. Other bleaching agents, *e.g.*, mercuric chloride and copper chloride solutions, did not give such good results unless considerably more care and trouble were taken.

In all cases the black deposit of silver is converted into an insoluble silver salt. Thus with the bleaching solution recommended the metallic image was converted into white silver ferrocyanide :—

$$4Ag + 4K_3FeC_6N_6 = Ag_4FeC_6N_6 + 3K_4FeC_6N_6$$

That this is the case was proved by exposing some precipitated silver chloride to the light and converting it into silver by ordinary development. The residue of silver was collected, washed free from all traces of developer, and then treated with potassium ferricyanide bleaching solution, which thereby became pale yellow, whilst the silver was changed to a white precipitate. The solution was filtered off and gave the usual reactions for potassium ferrocyanide, which were not given by the original ferricyanide solution.

In a typical quantitative experiment 0.1765 gram of exposed silver chloride gave 0.1094 gram of silver by development. Excess of potassium ferricyanide converted this into 0.1803 gram silver ferrocyanide. Treatment with sodium hydrogen stannite solution and subsequent washing and drying yielded 0.1130 gram of silver. These figures satisfactorily indicate that the reactions which take place follow the course outlined.

Further, when silver nitrate solution was treated with potassium ferrocyanide a white precipitate (of silver ferrocyanide) was produced, whereas when treated with potassium ferricyanide the silver nitrate gave a reddish brown precipitate (of silver ferricyanide).

To obtain the warm brown tones from the bleached prints these were then immersed in a bath of the alkaline stannite, when the image reappeared. The tin toning bath was made by dissolving 10 grams of sodium hydrate in 100 c.cs. of water. This solution was slowly added to the cloudy solution obtained by stirring 10 grams of stannous chloride crystals into 100 c.cs. of water, until the precipitate first formed re-dissolved; 100 c.cs. of water was then added. After standing, the clear solution was decanted off and contained approximately 2.5 per cent. of sodium hydrogen stannite, formed according to the equation :—

$$SnCl_2 + 3NaOH = NaHSnO_2 + 2NaCl + H_2O. + H_2O.$$

It has been shown elsewhere (*Chem. News*, 1922, 124, p. 215, April 21) that even when excess of alkali is used normal sodium stannite, Na_2SnO_2, is not produced.

For photographic purposes it was found advantageous to dilute this solution still further and use a 0.5 per cent. solution of the stannite, although at this dilution hydrolysis became apparent, since a white flocculent precipitate began to separate.

The chemical aspect of this toning process was investigated by treating the washed silver ferrocyanide, obtained as described above, with the alkaline stannite solution. This reduced it again to tin, sodium ferrocyanide and stannate being formed simultaneously according to the equation :—

$$Ag_4FeC_6N_6 + 2NaHSnO_2 + 6NaOH = 4Ag + Na_4FeC_6N_6 + 2Na_2SnO_3 + 4H_2O.$$

The dark insoluble residue produced in this reaction was filtered off and thoroughly washed to remove the sodium salts. It was quite insoluble in hydrochloric acid, but dissolved readily in

dilute nitric acid to a clear solution. Addition of hydrochloric acid to this solution gave a white precipitate (of silver chloride).

When this treatment was carried out quantitatively it was found that 0.1513 gram of the residue (silver), when dissolved in nitric acid and converted into the chloride with hydrochloric acid, gave 0.2009 gram of silver chloride. This corresponded closely with the calculated amount to be obtained from 0.1513 gram of pure silver.

It is thus established that this toning process with tin leaves an image of silver, whilst toning with sodium or ammonium sulphides converts the white silver salt (obtained by bleaching) into silver sulphide, *e.g.*:

$$Ag_4FeC_6N_6 + 2Na_2S = 2Ag_2S + Na_4FeC_6N_6.$$

Experimentally 0.1490 gram of silver ferrocyanide gave 0.1148 gram of silver sulphide on treatment with excess of a dilute solution of ammonium sulphide.

From the technical standpoint initial failures in this method of toning were largely due, strange as it may seem, to the thorough washing of the prints This entirely removed the sodium stannate and any meta-stannic acid, H_2SnO_3, which would result through the hydrolysis of sodium stannate on addition of water. Since colloidal silver absorbs the meta-stannic acid, producing a warm tone, it is advisable to simply remove excess of the alkaline tin solution by rinsing and allow the imperfectly washed print to dry.

The effect of subsequent immersion of the print in sulphide toning baths was tried, but did not appear to have any marked influence upon the final tone.

It is of interest to note that the alkaline stannite solution is able to reduce silver chloride to silver, which it does, whether this substances has been exposed to light or not. The reaction may be expressed :

$$2AgCl + NaHSnO_2 + 3NaOH = 2Ag + 2NaCl + Na_2SnO_3 + 2H_2O.$$

Lead is a metal which shows some chemical resemblances towards tin, and, since it is used in certain photographic processes, it was thought of interest to see if it could also be used for toning in alkaline solutions in the same manner as tin. Entirely negative results were obtained, however, using a solution of sodium hydrogen plumbite, $NaHPbO_2$, prepared from lead acetate solution and excess of sodium hydrate solution.

In his article Dr. Formstecher described various tin-toning baths and sometimes, carried out the process in two stages, using an alkali bath and one of stannous chloride. He also states that a bath of "tin salts" containing a little ammonia was suitable, and, unlike more acid solutions, has no eating-out effect on matt-albumen prints. The formula he ascribes to his "tin salts" is $Na_2SuCl_4H_2O$, but as the present writer has shown (*Chem. News*, 1918, 117, p. 193), sodium staunichloride has the formula Na_2SnCl_6 $6H_2O$.

Instead of using ordinary crystalline stannous chloride, $SnCl_2 2H_2O$, the more stable potassium or ammonium stannochloride was substituted for it in some experiments without any adverse effects being noticed. J. G. F. DRUCE, M.Sc., A.I.C.

FINDING CORRECT FOCAL LENGTH.

THE methods proposed for ascertaining focal length are quite numerous, but most of them call either for special apparatus or for the presence of a very distant object. In two of the best, a mark has to be made on the camera baseboard, which may be objected to.

One of the most convenient plans, requiring nothing but the camera and an ordinary foot-rule, is that originated by Mr. W. E. Debenham ("B. J.", September 19, 1879). In this, the rule is focussed sharply to a given definite scale or ratio, and the distance measured between rule and ground glass. This distance is then multiplied by the ratio, and the product divided by the ratio plus 1 squared. Or, to express it as a formula,

$$F = D \times \frac{R}{(R+1)_2}$$

For example, suppose an image of the foot-rule is focussed to exactly 3 in. long, or a ratio of 4, and the distance from rule to ground glass is found to be 53⅛ in. Then, $53\frac{1}{8} \times 4 = 212\frac{1}{2}$, and $212\frac{1}{2} \div 25$, or the square of $4 + 1$, $= 8\frac{1}{2}$ in. focus.

With careful focussing and measurement this method gives an absolutely correct result, provided the two nodes of the lens coincide, as in the case of the Cooke Series III., f/6.5, of 8½ in. focus. In the majority of lenses, however, the nodes do not coincide, so that the focus found by this formula will be a trifle too long or too short, according to whether the nodal space, or "NS," is plus or minus.

Now it is quite evident, by using a little thought, that the error will be equal to $\frac{R}{(R+1)^2} \times NS$. Suppose, for instance, a lens is of 6-in. focus and the ratio is 3, the correct distance between rule and ground glass being theoretically 32 in. If there is a plus nodal space of ½ in., the distance will really be 32½ in., and the focus, by Mr. Debenham's formula, will work out as $6\frac{3}{32}$ in., which agrees with the stated amount of error, for $\frac{3}{16} \times \frac{1}{2} = \frac{3}{32}$. Again, if the nodal space is minus ½ in., the distance would be 31½ in., and the focus will work out as $5\frac{29}{32}$ in., which is once more an error of $\frac{3}{32}$ in., only minus instead of plus. Obviously, to obtain the smallest amount of error the image should be as small and the distance as large as possible, though this certainly introduces more opportunity for a mistake in measuring. If the ratio is 9, the error will be only 9 per cent. of the nodal space, which is practically negligible.

The writer has found, however, that by somewhat modifying Mr. Debenham's very useful formula, it is quite a simple matter to eliminate the error, thereby obtaining the exact focal length. Suppose, for instance, in testing a lens by the foregoing method the ratio is 4 and the measured distance 62.7 in. Instead of proceeding to calculate, focus the rule sharply to another larger ratio, say 5, and again measure the distance, which turns out to be say, 72.2 in. The true focus can then be found by the following formula, in which D_1 and D_2 are the two distances, while R_1 and R_2 are the corresponding ratios :—

$$\frac{D_2 - D_1}{\left(R_2 + \frac{1}{R_2}\right) - \left(R_1 + \frac{1}{R_1}\right)}$$

Thus, in the example just given, the calculation would be :—

$$\frac{72.2 - 62.7}{5\frac{1}{5} - 4\frac{1}{4}} = \frac{9.5}{\frac{26}{5} - \frac{17}{4}} = \frac{\frac{95}{10}}{\frac{19}{20}} = 10 \text{ in., the correct focal length.}$$

Incidentally, we can now, if desired, ascertain the nodal space itself, by working out the focus from one of the distances with Mr. Debenham's formula, and noting the error. For instance, with a ratio of 4 the distance was 62.7 in., while 62.7 multiplied by 4 and divided by 25 equals 10.032 in. The error, therefore, is 0.032 in., and is plus. Now the nodal space will equal the error divided by :—

$$\frac{R}{(R+1)^2}, \text{ or } \frac{32}{1000} \div \frac{4}{25}, \text{ or } \frac{32}{1000} \times \frac{25}{4}, = +0.2 \text{ in.}$$

The foregoing formulæ are only offered as being of great assistance when the focus has to be known with absolute precision, as in copying, enlarging, or reducing to an exact scale, or deducing measurements from photographs. It will have been noted that Mr. Debenham's very ingenious and simple method has so small a percentage of error that it is quite sufficiently accurate for all ordinary purposes.

A. LOCKETT.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Latest date for entries, July 22. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for Entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 28.—Portsmouth Camera Club. Latest dates : Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

Assistants' Notes.

Notes by assistants suitable for this column will be considered and paid for on the first of the month following publication.

Self-Confidence and Enterprise.

"WHAT shall I do to get on?" is a question that every business man asks himself at some time or other, and the man who escapes the necessity of asking it at times like the present is fortunate. With some of us it is probably, "What shall I do to live?"

There was a time when all one had to do was to sit tight and wait for the work to roll in, and if things were not quite satisfactory, there were vacant positions to be had and branch studios to be opened. There are still vacancies, but they are snowed under with applicants, and though branches can still be opened, there is no certainty of their being patronised. The present general uncertainty of affairs is largely responsible for the poor state of the photographic business, and the uncertain weather has not helped to mend matters. Under these conditions it is a hopeless policy to expect work or business to come to us, or to meet us on the way. Both have to be caught and forcibly laid hold of. This is where the value of self-confidence and enterprise is apparent.

The applicant for a position to-day must do something more than write the orthodox letter "begging to apply for the post." That may stand one chance in a hundred; in a recent vacancy I know of forty-odd letters stood no chance at all, though coming from seemingly efficient people. To make sure of getting a post, or as sure as is humanly possible, one must apply expeditiously, determinedly, and personally. And the same thing applies to the owner of a business who wants business. He must find it, hold it, and keep it; and do it expeditiously, determinedly, and personally if he would be sure about it. Now, unless one has a heap of self-assurance, nothing will seem more distasteful or distressing than personally approaching people in a probably unsuccessful endeavour to extract money, either as work or trade. But the ordeal is not at all bad to the self-confident, enterprising party, who, being naturally optimistic, is not easily downcast or discouraged. His efforts are not *all* unsuccessful, and if he is sensible he does not expect them all to succeed; therefore he expects and gets a percentage of results. There is nothing very terrible about interviewing a stranger at one's own invitation. He or she may prove an ogre or ogress, but in any case some little interest will be experienced at least, and there is always the possibility of future results.

But, you may say, self-confidence and the spirit of enterprise are gifts. If one is not born with them, what then? In that case the former can always be simulated and the latter developed. In illustration of this I will relate a true case, the details of which I can vouch for. It is not an isolated example by any means; I could quote at least one almost absolute parallel. The photographer in the case was not born with any gift of self-assurance or assertiveness. Quite the reverse. He was of the type which enters a shop to sell wholesale, and buys something retail as an excuse for going in—and for getting out as quickly as possible. But this individual realised his deficiency, and knew that it had cost him many lost opportunities. So he forced himself to act as though he were just over from the States selling Cantaford cars at so much per gross. And by and by it became a habit, until to-day he cannot help it. It has become second nature to him. He revels in it. Enterprise cannot be called a gift; it is purely a matter of serious thought combined with the ability to act quickly and at the right time, and our friend kept this before him during the time I am going to speak about. It happened that he badly wanted a change, and for the first time in his career he experienced a difficulty in finding a new post that suited him. At last he decided to open up a new business, although his district was already overloaded with photographers and trade was at a low ebb. First he considered the various fields in which it was possible to practice photography, and, having decided which was the most likely to take root, he looked for possible customers. After interviewing (unannounced) some dozen strangers and receiving only five rebuffs, he thought the thing was good enough, and proceeded to the next move. This was to find financial assistance. Some, similarly situated, might have approached friends, or else professional financiers. Not so our friend. He marked down the hardest business man in the neighbourhood, and, being satisfied that this gentleman had both premises and means, he boldly suggested that they should open a new business in partnership. Although a total stranger, his suggestion was received with interest, and eventually the idea became a fact, and to-day the affair is going along well, in spite of adverse conditions in the locality.

The spirit of enterprise helped to follow up the self-confident start, by introducing and pushing new lines, seeking orders in unlikely places, and advising and assisting trade customers to improve their business. And self-confidence—or was it, rather, "cool cheek"?—still kept pace, as the following example proves. He heard that a certain party was about to be married, and the thought struck him that possibly there might be a good order for wedding groups. So he inquired the address of either of the parties, but no one knew where they lived. All that he could find out was that the young lady worked for Messrs. Dash, and Messrs. Dash were rivals of ours. That would have caused most of us to let the matter rest, but this photographer just stepped to the 'phone, rang up Messrs. Dash, and inquired for the address of Miss X., the young lady who had just left to get married, got it, went round to see her, and secured an order to appear on the wedding day and take the groups.

This, of course, might appear to be carrying self-confidence too far, and raking the ill-feelings of other photographers, but this is to some extent a matter of opinion, and many business people would say that it was merely a legitimate business move. In any case, it serves to show that trade can be obtained by deliberate intention.

There is a side to this question which I must not overlook. It is the capability or otherwise of a photographer to carry out the engagements and contracts which he may obtain by push and enterprise. In the instance just mentioned, the photographer's initiative would have done him more harm than good if, after getting the business, he had proceeded to make a mull of the work. Before going out after work, one must be confident, not only of getting it (or making a good bid for it), but also of being able to handle it to everyone's satisfaction when it is obtained. This brings us to the occasional case where there is a doubt. A good example of this occurred to me lately. I was asked to recommend a really good technical photographer to undertake some difficult work. Details of the work were not at hand, but I was given to understand that it was not easy to get the negatives or to please the party concerned. My first thought was to claim the business myself; my second was, Was it in my scope? I asked for the address, and called at the place where the work was. I found that while it was not beyond what I catered for, there certainly would be some doubt about getting the required results under the available conditions. I had not so far committed myself, and could have turned it down without loss of prestige, but decided that I might as well have it if it could be had without calamity, so I said that I could undertake it at such and such a price, and as there seemed some little uncertainty about satisfying the owner, I would make a sample negative and print at a nominal charge before proceeding further. The suggestion was received favourably, and I was informed that others had been given this work, and had started off with a number of exposures, the results of which were worthless, although charged for at full price. On showing up the sample, I discovered exactly what it was that was required, and also that I could do it, and I consider the trouble taken and the small risk of lost time, etc., were well repaid. Work that is normally outside one's usual business is sometimes worth tackling for more reasons than the profit on it. Such work successfully done means valuable experience, and may add substantially to one's reputation. Confidence and enterprise will obtain outside and new business for those who can do it. It only remains for me to add that, given these qualifications, one should not carry anything to the point of absurdity in undertaking an obvious impossibility, as that extreme would be just as bad as the other. A glaring example of what I mean would be the tackling of micrographic work on metals by a photographer who had no proper apparatus for the work, and did not know where it would be obtained or how it was used. And yet I believe that this class of photography is to be had by those who have the confidence to go after it. And though I don't pretend to know, I should think that it would be profitable work, too. A much simpler instance, and one which occurs, is the promising of a portrait or amateur

service in some particular style, in a time limit or at a price which is not reasonably possible. The confidence to go so far is misused, because the results end in a loss. But within the wide limits of practical possibility and reasonable profit, self-confidence and enterprise can be exercised to good purpose and with marked effect.

THERMIT.

Patent News.

Process patents applications and specifications—are treated in "Phota-Mechanical Notes."

Applications, July 3 to 8:—

PHOTOGRAPHY.—No. 18,356. Photography.—D. Newman.

APPARATUS.—No. 18,810. Photographic apparatus.—H. Diernhofer.

APPARATUS.—No. 18,373. Optical apparatus for reflecting photographic images.—C. van Soolen.

PROCESSES.—No. 18,311. Photographic processes—A. L. and M. Landan.

LENSES.—No. 18,341. Photographic lenses.—J. W. Hasselkus, G. Richmond and Ross, Ltd.

FLASHLIGHT.—No. 18,670. Apparatus for operating camera shutters and igniting powder, etc., from a distance.—R. E. Stephens.

CINEMATOGRAPHS.—No. 18,635. Cinematograph cameras.—E. B. Wedmore.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

AUTOMATIC AIRCRAFT CAMERAS.—No. 175,449. (November 29, 1920). As usual in mechanism of this type the air screw (not shown) drives a shaft 1 on which is mounted a worm 2 to drive a worm wheel 3 in one with a pinion 4 in gear with the gear wheel 5 meshing with the mutilated wheel 6, which wheel controls the operations of shifting the films and winding and setting the shutter between exposures and controlling the operations of releasing the shutter to make the exposures. This wheel 6 is held in the position in which its mutilation is adjacent to the wheel 5, and the mechanism disconnected, by a stop 51 coming into contact with the end of the spring con-

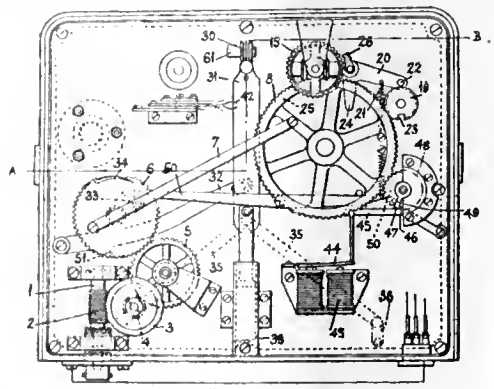

Fig. 1.

trolled lever 50 until the lever is moved clear of the stop by its opposite end being engaged by a member 49 carried by the blind shutter roller on the release of the shutter by an exterior time switch.

The mutilated gear wheel 6 is connected by means of the link 7 with the toothed wheel 8 (or alternatively a segment) which turns the receiving spool 18 and resets the blind shutter roller 48. A convenient form of gearing connecting the wheel 8 with the spindle of the receiving spool is shown by way of example in figs. 1, 6, 7 and 8. This wheel 8 is in engagement with the spur wheel 9 in one with a ratchet member 41 (fig. 6), which wheel 9 is free to run on the spindle 10 driving the receiving spool, and is also in one with the bevel wheel 11 in gear with the bevel gearing 12, 13, the wheel 13 being fastened by the pin 14 to the end of the driving spindle 10. The large gear wheel 15 carries the bevel wheels 12. It will be obvious from this arrangement that so long as the wheel 15 is free to rotate, the

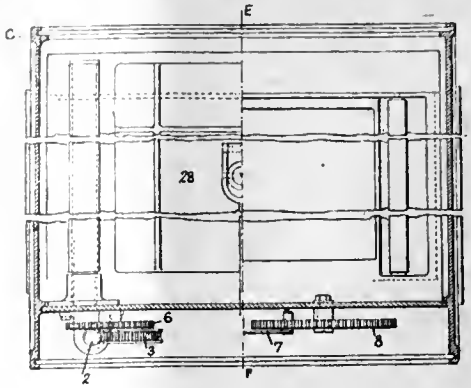

Fig. 2.

members of the bevel gearing will operate in opposite directions and the shaft 10 will remain stationary. When, however, a pawl 26 is brought into engagement with the wheel 15 to lock the wheel, the bevel 11 will transmit its motion direct to the bevel 13, and consequently to the shaft 10 carrying the receiving spool.

In order that a regular amount of film may be moved across the gate on each forward movement of the wheel 8 the film is passed from the gate over a measuring drum 17 (fig. 4) to the receiving spool 18. This measuring drum is in one with the notched disc 19 (fig. 1) co-acting with a lever 20 controlled by the spring 21 adapted to hold the member 22 in engagement with the periphery of the disc 19 during the rotation of the disc. The member 22 is adapted to enter the notch 23 in the periphery of

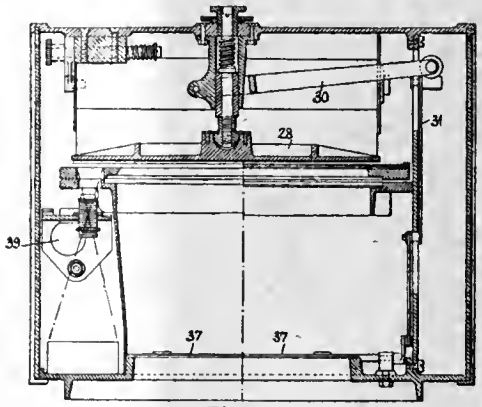

Fig. 3.

the disc 19 when the notch registers with the engaging member, and thus prevents any further movement of the measuring drum until the member is moved out of engagement with the disc. The spring controlled lever 20 is provided with an arm 24 adapted to be engaged by the pin 25 on the back of the wheel 8 and to lift the member 22 on its free end, out of engagement with the notch 23 against the influence of the spring 21 controlling the lever 20 and simultaneously to bring the pawl 26 into engagement with the wheel 15 co-acting with the bevel gearing through which the receiving pool is driven from the wheel 8.

From the above description it will be understood that when the measuring drum is free to rotate to measure a length of film drawn from the gate while the pawl 26 is in engagement with the wheel 15, and consequently the receiving spool is driven from the wheel 8 through the bevel gearing 11, 12, 13. When, however, the movement of the measuring drum is prevented, owing to the engaging member 22 at the end of the lever 20 dropping into the slot 23 in the disc 19, the pawl 26 is out of engagement with the spur wheel 15, and consequently the wheel is free to rotate, and the shaft 10 driving the receiving

spool 18 is stationary. The spring controlled balls 411 of the ratchet member 41 (figs. 6 and 8) co-act with an internally toothed ring (not shown) at the end of the spool 18 and prevent any backward movement of the said receiving spool.

The film in its passage from the supply spool 27 to the receiving spool 18 is adapted to pass under the pressure pad 28 (figs. 3 and 4), which pad is designed to hold the film against a glass plate 29 forming the film seat at the moment of exposure. This pressure pad is actuated through a lever arm 30 connected to the upper end of a vertical member 31 (figs. 1 and 3). This vertical member is attached to and actuated by a lever arm 32 adapted to be engaged by a roller member 33 projecting from the rear face of the mutilated wheel 6. During a portion

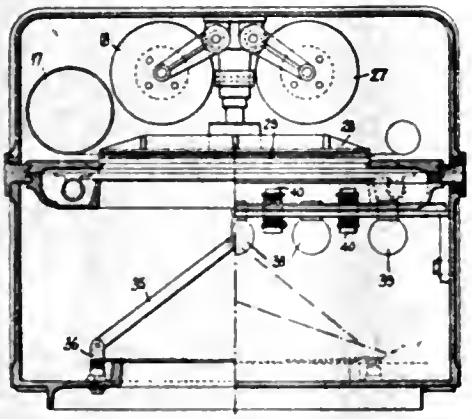

Fig. 4.

of the revolution of the wheel 6 the lever 32 is pressed down and with it the vertical member 31 and the pressure pad 28 connected with the upper end of the member 31 through the arm 30, while during the upward movement of the roller 33 the lever 32 follows the roller and carries the mutilation 34 on the periphery of the wheel 5 past the driving wheel 5 when the stop 51 is released by the lever 50, and thus brings the wheel 6 into mesh with the wheel 5. The lower end of the vertical member 31 is connected by links 35 (figs. 1 and 4) with the cranks 36 on the spindles carrying the capping flaps 37 (fig. 5), so positioned that when the vertical member 31 is pressed down to bring the pressure pad 28 against the film in the gate the capping flaps

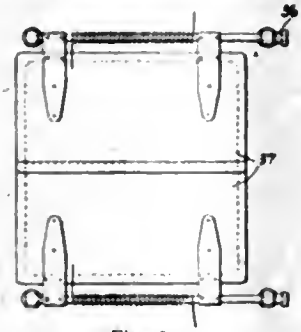

Fig. 5.

are raised to allow of an exposure being made. The upward or return movement of the vertical member 31 under the influence of the capping flaps 37 is retarded by a dash pot 38 at the lower end of the member. As above described, the upward movement of the arm is adapted to turn the mutilated gear wheel 6 at the desired moment until its mutilation 34 has passed the point of contact with the periphery of the driving wheel 5, and the driving wheel is again in engagement with the teeth on the unmutilated part of the periphery of the wheel 6, thus bringing the mutilated wheel 6 into gear again for a fresh cycle of operations.

In aircraft cameras means have been provided for photographing the faces of clocks and other recording instruments at the moment when the exposure is made. Hitherto it has been usual to arrange these instruments outside the camera casing.

According to the invention a series of instruments are arranged within the casing and their faces are lit up by electric lamps 39 (fig 4), thus providing for a series of photographs of these instruments to be taken along the edge of the film through a corresponding series of small lenses 40 mounted within the casing. The lamps are lit up during the exposure and no other shutter means are necessary for the lenses registering with the faces of the instruments.

The member 31 is provided with an ebonite striker 61 adapted to engage the electric contacts 42 (fig. 1) to light the electric

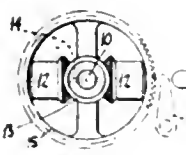

Fig. 7.

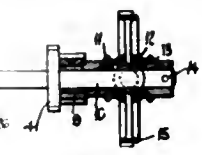

Fig. 6.

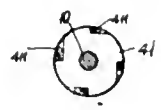

Fig. 8.

lamps 39 at the moment when the film is held in the gate by the plunger 28 and the capping flaps 37 are raised for the exposure of the film.

The release of the shutter is controlled by an exterior time-switch which may be placed in any convenient position for the pilot or observer to operate. The operator sets the time-switch to release the blind shutter to make exposures at pre-determined intervals of time. The control mechanism is shown by way of example in fig. 1. The release of the switch is adapted to energise the solenoids 43, thus actuating the contact 44 and moving the lever arm 45 to a position in which its shoulder 46 is clear of the dog 47 and releasing the blind shutter roller 48. The rotation of the roller 48 brings a projecting pin 49 into contact with the end of the spring controlled lever 50, thereby raising the other end of the lever to a position in which it is clear of the stop 51 on the back of the mutilated gear wheel 6 and allowing the gear wheel to be turned to a position in which the mutilation 34 on the periphery of the wheel has passed the point of contact with the driving wheel 5, thus allowing of a fresh cycle of operations actuated by the air-screw to bring a new length of film into the gate and to rewind and set the shutter.—Colin Martin Williamson, Litchfield Gardens, Hawthorn Road, Willesden Green, London, N.W.10, and Frederick Charles Victor Laws, Air Ministry, Alexandra House, Kingsway, London.

The following complete specifications are open to public inspection before acceptance:

Colour Photography.—No. 182,476. Process for the production of transparencies for the projection of photographs in natural colours.—H. Diernhofer.

New Books.

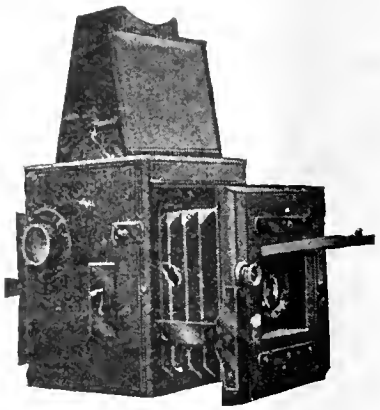
The A.B.C. of Wireless.—However little knowledge one may have of the higher technics of electricity, it is impossible to restrain a curiosity regarding the ways and means of the triumphs which have been accomplished in the field of wireless telegraphy, particularly so when inventors crop up every now and again with promises of the wireless telegraphy of photographs. This little manual is written for the purpose of giving an answer in non-technical language to the question, "How is it done?" The author, Mr. Percy W. Harris, editor of "Conquest," writes interestingly and very simply of the evolution and modern achievements of wireless, and contrives to give to the most non-technical reader a reasonably comprehensible account of the electrical methods by which telegraphy and telephony through space have reached their present degree of efficiency. The little book contains a final chapter of advice on the purchase of a wireless set by those wishing to occupy their leisure time by "listening-in." The book is published by the Wireless Press, Ltd. 12-13, Henrietta Street, London, W.C.2, price 6d. net.

Photographic Companies.—The particulars of company registrations at Somerset House for the first six months of the present year, which are issued by Messrs. Jordan, 116, Chancery Lane, London, W.C.2, include one public company relating to photography with a capital of £25,000, and twenty-one other companies of an aggregate capital of £244,662.

New Apparatus.

The Zodel Reflex Camera. Sold by Wallace Heaton, Ltd., 119, New Bond Street, London, W.1.

A QUARTER-PLATE British made reflex camera, complete with f/4.5 anastigmat, for less than £17 is a sign of the recovery to pre-war values which is being made in photographic apparatus. In offering the Zodel camera at this price Messrs Wallace Heaton are pursuing the policy adopted in their supply of both new and second-hand appliances, namely, that of offering reliable goods at such a narrow margin of profit that the retail purchaser is enabled to buy at prices not much in excess of those to which he was accustomed before the war. The Zodel reflex, which we have had an opportunity of trying is a thoroughly well made instrument, in which the features which are of importance in reflex work have received full consideration. In the first place it is rapid in action. The shutter is set by a single turn of the large winding key, which serves also for adjusting the speed of exposure for any time on the scale marked from 1-1,000th to 1-10th of a second. This is the



only movement required in preparing for a further exposure, since the mirror is of the type which automatically falls after the exposure. The arrangement of the shutter allows of the time of exposure being lengthened, though not shortened, without releasing the shutter and setting it afresh. A very good feature is the hinging of the frame which carries the hood, thereby rendering the focussing screen instantly accessible for cleaning from dust, which, as every user of a reflex knows, interferes with accurate focussing. In the quarter-plate size the extension is just over 9 inches, and the rise of front three-quarters of an inch. The camera is built square and is fitted with substantially made rotating back for horizontal or upright pictures. The lens is completely sunk in the front board of the camera, and, when not in use, is covered by a hinged flap which, when raised, forms a useful sky shade. As supplied, the Zodel is fitted with double solid pattern dark slides of the kind in which the two are inserted back to back at one end of the holder, which is closed by a cross piece secured by a pair of brass clips.

The price also includes a detachable back focussing screen and hood for use when the camera is used on a tripod or in any position when it is inconvenient to observe the image through the customary upright hood. The Zodel is made in two sizes, namely, 3½ x 2½ and quarter-plate. Without lens and with one double dark-slide the respective prices are £13 15s. and £14. The instrument may be supplied with lens by any leading maker, and its design and mechanical quality are deserving of a first-rate optical instrument.

THE ECONOMY EXPOSURE CALCULATOR.—The substitution of calculation for trial-and-error methods in ascertaining the exposure for development papers in enlarging and contact printing is an aim which has our hearty approval. It is the aim of the present "calculator," which consists of a booklet of instructions, a pair of logarithmic scales, and a sheet of tracing paper, the latter for use in the method of measuring the density of a negative which forms part of the system. Nevertheless, we cannot think there is much to be said in favour of the system which is advocated. For one thing, it involves more preliminary work than, we are persuaded, the professional or amateur printer will undertake. For another, the method adopted for "measuring" the densities of negatives is not one in which confidence can be reposed. No sensitometric system of exposure calculation in printing or enlarging can be simple in use, but the basis should at least be accurate, and in that respect the present system is open to serious objection.

Briefly, the system consists (1) in obtaining a figure for the density of a negative by a method to which we will refer directly. Then (2) the exposures respectively required by what is termed a "standard" negative on various makes of paper with the customary intensity and distance of the printing light are ascertained by trial. Finally (3) with negatives of different density the exposures under the same conditions of paper and illumination will be in the ratio of the negative "densities," a logarithmic disc calculator being provided for facilitating this computation. This last item in the system might be allowed to pass if the "density" figures represented the relative opacities of the negatives, but, if we describe the method adopted for the "measurement" of the so-called "density factor," it will be seen that the latter is not a measure of the light-stopping properties of a negative.

The negative is placed in a printing frame and backed by a piece of tracing paper, and the two kept in place by inserting a sheet of clear glass and one half of the hinged back. The frame, thus displaying half of the negative, is placed upright on a bench and a light-source, such as a candle, placed 2 ft. from it facing the front of the frame, i.e., the negative. In line on the other (rear) side of the frame a light-source of equal intensity is moved to and fro until the details of the negative just disappear from the tracing paper, which faces light No. 2. Such a method, however, is not a single measure of the highest density in the negative. It is not, as an amateur contemporary erroneously states, the grease-spot method. The contrast of the negative, and in particular the juxtaposition of greatly different patches of density largely enter into the measurement; for which reason the resulting "density factors" are not comparable except in the case of negatives of normal contrast containing light and dark patches close together. Thus, in our opinion, exposures calculated on this basis will frequently be entirely misleading, according as the negatives differ in contrast quality from the "standard." The booklet describing the system is supplied by J. Darby, South Street, Barming, Kent, price 2s. 6d. post free, inclusive of the disc calculator and the sheet of tracing paper.

CROYDON CAMERA CLUB.

Affairs resumed a photographic aspect last week when the cheerful, confident, and combative Mr. Vivian Jobling briefly demonstrated a "Magic Mask." By means of straight cuts in combination, it is believed, with a novel method of folding the paper, rectangular masks of any required size can be produced with ease, and with no fear of cross-cutting the corners. Even if the folding part of the business should happen to be a bit out, final correction is easy with two strokes of the knife. The ingenious stunt is well worth publication, but is impossible to describe without diagrams. It would add an attractive turn to the repertoire of any paper-manipulating street artist.

A discussion followed on the new Barnet matt emulsion plate, and its halation-resisting qualities. It was generally agreed that the opacity of the film would eliminate halation, or reduce it to negligible proportions, but some surmised this would be at the expense of irradiation, or spread of light from particle to particle. Mr. Purkis was of opinion that although irradiation was bound to occur in such a turbid medium, yet it would be confined within such narrow limits as not to interfere materially with sharpness of outline.

The president, Mr. John Keane, said that the ready way in which the film took pencil, should render the plate of great service to the pictorialist. When enlarging from the matt emulsion plates, with a sheet of ground glass placed behind the condenser, he had met with granularity in the print, despite assurances to the contrary. Mr. Salt pointed out that a sheet of glass ground on both sides gave the maximum diffusion or scatter, with the minimum obstruction of light. It was superior in this respect to two sheets of glass similarly ground, but on one side only, with or without an intervening air space.

The evening concluded with a consideration of a proposition by Mr. Catharine that in future the proceedings of the club should be opened with prayer. He is now resident in Tonbridge, and it appears its Town Council have adopted the plan, despite strong opposition from a member, who pointed out that Parliament had long since followed a similar course without appreciable benefit.

As a start, Mr. Catharine suggested that the president should read a sort of non-sectarian Collect. A paragraph from Communication No. 144 from the research laboratory of the Eastman Kodak Co. relating to Einstein's hypothesis of 1905, which recently appeared in the "B.J.," he regarded as being suitable. The reading of this paragraph put the lid on the proposition, which was unanimously rejected.

News and Notes.

HAMMERSMITH PHOTOGRAPHIC SOCIETY.—Owing to a fire at Hampshire House, weekly meetings have been suspended until further notice.

RESTRICTING POLICE-COURT PHOTOGRAPHY.—Judges and magistrates are slowly but surely putting a ban on photography in police courts. Notices in Bow Street and other police courts concerning the use of a camera are being placed in more prominent positions, and the police officers are becoming more alert. Mr. Justice Shearman stated at the Staffordshire Assizes last week that he noticed with concern that one of the newspapers published a photograph of an accused man who was in the dock the day before. To his mind it was neither decent nor proper that a court of justice should be turned into a theatre, and as far as it was within his power he intended to take measures to stop photographs being published during the trial.

PORTSMOUTH CAMERA CLUB.—The twenty-eighth annual exhibition will be held from October 18 to 28. There are four open classes, one for portraiture and figure studies, another for other subjects, and two others for lantern-slides (monochrome) and colour transparencies. Awards and certificates will be offered in each class. For convenience of hanging, standard size mounts are requested, of vertical measurement, 25, 20, 16 or 12 inches. In the open classes an entry fee of 1s. per print is charged, and the same amount for each four slides or colour transparencies. The latest date for entry forms is October 11; for exhibits, October 16. Prospectus and entry form from the hon. secretary, Mr. C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

FINGER-PRINT PHOTOGRAPHS BY WIRELESS.— M. Bélin is stated to have already invented an instrument whereby photographs not only of persons, but of finger-prints can be sent by telephone. He now declares (says the "Star") that, by means of his instruments, he can send equally good photographs by wireless. There is, as a matter of fact, a system, known as the Collins Code, by which descriptions of finger-prints can be telegraphed. By this system the finger-print is sent by telegraphing numerals, and these, when "translated" by the receiver, give the lines. The trouble is that, at best, this is but a description of the finger-print, and that if one figure in the wire is wrong, the value of the whole print may be destroyed. M. Bélin's prints, on the other hand, are actual photographs.

ALL-BRITISH £3,000 COMPETITION.—A most enjoyable luncheon gathering was held on Tuesday last, at which members of the photographic trade and Press had an opportunity of seeing something of the large entry of prints received in Part I. of this competition, which closed on June 30 last. Two of the judges, Sir William Orpen and Mr. Gordon Selfridge, were prevented from being present, but Miss Neilson Terry, Mr. Wastell, and Mr. George Robey were there. Mr. Edgar Houghton, who presided, said a few words by way of emphasis of the success which had attended the competition, and declared that his arm ached from the labour of signing the many cheques which were shortly to be forwarded to successful competitors. The full list of the awards to camera users and dealers will be published within the next few days.

PHOTOGRAPHY IN TIBET.—The British Buddhist Mission to Tibet left London last Friday for Lhassa, a photographer, Mr. W. Harcourt, being one of the party. It was stated at a farewell dinner that the mission would begin their long march to the great roof of Asia from Darjeeling. They would climb from Gongtok to a plateau 14,000 feet high and then tramp to the Brahmaputra River, down which they would float for 160 miles on a raft to Chaksam. There the final stage of the journey to Lhassa would begin. The journey down the Brahmaputra River to a point 30 miles from Lhassa would be the first ever undertaken by Europeans. Photographic and film records will be secured of the country, of the customs, folk-dances, occupations, and everyday life of the people, as well as of the religious ceremonies and processions, which are at present enshrouded in mystery.

A LARGE BARGAIN LIST.—Messrs. Robbins, Manistre (The London Camera Exhange), of 2, Poultry, Cheapside, London, E.C.2, have just issued an exceedingly well-arranged list of their stock of second-hand cameras, lenses, etc., amounting to very nearly 1,000 separate items and sets. Every individual piece of apparatus is identified by the firm's stock number, and the list has been published only after very careful comparison between the printed particulars and the actual specification of the goods. Both the professional and amateur photographer will find in these pages particulars of cameras, lenses, enlargers, of all types from the largest to the smallest, and may accept with confidence the firm's assurance that prices have been liberally marked down to the current market level. Moreover, Messrs. Robbins, Manistre, recognising that professional photographers obtain a trade discount in purchasing their business supplies, extend this benefit also to the second-hand apparatus which they supply. The prices named in the present list are thus subject to 10 per cent. discount in the case of purchases by bona-fide professional photographers. The list, which is certainly one which should be obtained, is obtainable post free on application.

COARSE-GRAINED NEGATIVES.

To the Editors.

Gentlemen,—On page 424 of the "B.J.," dated July 14, in reply to a correspondent the coarse grain of rapid plates is referred to, and (presumably) the querist is advised to use isochromatic plates—with full exposure and a weak developer—if a very fine grain is required, or, of course, very slow ordinary plates. The latter have been recommended and used for generations in cases where the finest of grain is wanted, but the recommendation of iso plates for fine grain is new to me; in fact, experiments made some years ago proved, without the slightest shadow of doubt, that, all other things being equal, iso plates gave a more pronounced grain than ordinary plates.

Old hands will perhaps remember that in December, 1891, when a certain well known firm introduced the first popular iso plate, the grain was so coarse that it threatened to be a failure commercially. Happily, however, improvements were quickly made, and the plate became a big success, but the grain was never so fine as an ordinary (non-iso) plate of the same speed. All iso plates have improved

since those early days, but some further experiments carried out in later years—but before the days of the self-screen plate—showed that iso plates were still more grainy than the ordinary brand, and the experiments I made were repeated—and my opinion confirmed—by the late Mr. J. I. Pigg, who made the most careful microscopical examinations of the developed image.

A plate, no matter what make, is not always to blame in cases of pronounced grain, for the developer and the method of drying each play their part in governing the amount of grain—the method of drying perhaps being the most important.

A pronounced grain is more common in summer than in winter, the temperature of the atmosphere during drying affecting the grain to a far greater extent than the average worker imagines. The more quickly a negative is dried, and the warmer the air in which drying takes place, the coarser will be the grain. This may be proved very easily by cutting a plate in halves, drying one half as quickly as possible in a warm place, the other half in a cooler place, and examining under a microscope. Indeed, with some plates a microscope will not be necessary, the difference in grain being visible to the naked eye. As heat increases grain, it will be obvious that a warm developer will do its work in producing it, and when the finest of grain is wanted, it is not advisable to have the temperature of the developer above 65 deg. Fah.

There are, I believe, several theories concerning grain, old authorities differing on the matter. It is, therefore, one that might claim the special attention of present-day photographic investigators.—Yours faithfully,

GAMMA X.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

L. J. BOON.—We think the lens you require is the Dallmeyer f/2.9 "Pentac" anastigmat portrait, which is made in focal lengths up to 12 inches. The latter is listed for a 7 x 5 plate, the 10-inch for a half-plate.

J. H.—We have found nothing better than thin nainsook for diffusing the light of half-watt lamps. It is more durable than tracing cloth, and can be washed when dirty. The General Electric Co., Magnet House, Kingsway, London, W.C.2, give special attention to lamps for photographic work. Six 1,000 c.p. lamps make a very good installation. By having so many lamps you get better diffusion than with fewer of the same total candle-power.

B. W.—We do not think that acetylene burners are at all suitable with the vertical enlarger. We think you would lose a good deal of light by burning flames in a horizontal position which are intended to burn vertically. If you cannot get electric light we think it would be better to use a set of inverted "Howellite" incandescent gas burners, or one good burner of this type in conjunction with a condenser. The "Howellite" burners are supplied by Messrs. J. J. Griffin & Sons, Ltd., Kemble Street, Kingsway, London, W.C.2.

M. T.—The addition of potash metabisulphite to the fixing bath keeps the latter from becoming discoloured, and in that respect is certainly an advantage in handling bromide prints. In fact, the bath will keep almost free from colour as long as it retains its fixing powers. Therein, on the other hand, lies the danger of using it after it has reached a state of exhaustion when it is incapable of fixing prints quickly. For this reason many photographers prefer to use a plain hypo bath, which becomes coloured as prints are fixed in it, so that the discoloration of the bath is a certain rough indication of its progress towards exhaustion. If you do not stint the fixing solution, but use plenty of it in the routine fixation of prints, unquestionably it is better to add the metabisulphite.

H. S.—If you carry on a separate business under a name which is not your own, under the Business Names Act you are required to register that business, even though financially it is one with your chief establishment. The object of the Business Names Act is to disclose to the public the proprietors of businesses with which they deal, and, therefore, we expect that the case of a subsidiary business is provided for. The form for registration is obtainable from the Registrar of Business Names, 3-4, Clement's Inn, London, W.C.2. Under the Act you are required to put your real name on all essential business literature, such as invoices, etc., but it is not necessary to put the real name on mounts, nor to display it on the outside of the premises.

A. C.—About the only method for toning a bromide print yellow is to bleach in the lead intensifier and then to immerse the print in a bath of potass bichromate. This gives a yellow image, but much paler and less full in colour than the specimen you send. Formula for the bleaching solution is:—

A.	Lead acetate	1 oz.
	Acetic acid	1½ drs.
	Water	20 ozs.
B.	Potass ferricyanide	1 oz.
	Water	20 ozs.

A and B are mixed together to form the bleaching solution. The bleached print is washed for half an hour or more in running water and is then placed in a 5 per cent. solution of potass bichromate. It is advisable to pass prints through a weak bath (about 2 to 3 per cent.) of nitric acid after bleaching and before treating with the bichromate.

B. C.—Thomas's formula for purple tones in their lantern-plates was:—

	No. 1.	
Pyrogallic acid	1 oz.	30 gms.
Metabisulphite of soda ...	1 oz.	30 gms.
Water to	80 oz.	2,400 c.c.s.
	No. 2.	
Ammonium bromide	8 oz.	240 gms.
Liq. ammonia (.880)	4 oz.	120 c.c.s.
Water to	80 oz.	2,400 c.c.s.

Use equal parts of each solution. This developer allows great latitude in exposure, and takes from 3 to 12 minutes to develop, according to the amount of exposure given. When using this developer the image will appear buried and lacking in density if examined by ruby light, but, when fixed, will be fully dense, and the deposit will appear opaque by reflected light and purple by transmitted light, improving in colour when dry.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3247. Vol. LXIX. FRIDAY. JULY 28, 1922. Price Fourpence.

Contents.

SUMMARY.

In a communication from the British Photographic Research Association Mr. F. C. Toy criticises the experiments on which is based the view that the phenomena of the action of light on the ultimate grains of an emulsion afford support for the modern quantum theory of light. (P. 443.)

In an article on the focal-plane shutter, published in "American Photography," Mr. Charles T. Jacobs gives some useful advice on obtaining the best results from this type of shutter by employing high-tension in place of narrow slit when the shortest exposures are required and when a large aperture of lens is being used. (P. 445.)

In the current issue of the "Journal of the Society of Chemical Industry" clean scrap iron is recommended for recovery of the silver from spent fixing baths, etc. The writer, Mr. E. Gardner, gives directions for making the filter-cloths for collection of silver residues. (P. 447.)

At the last meeting of the Council of the Professional Photographers' Association reports were made of the favourable arrangements in progress for the forthcoming Congress. Mr. W. E. Gray was able to announce that a satisfactory decision had been obtained from the railway companies regarding the conveyance of apparatus as photographers' luggage. (P. 451.)

A suggestion which would perhaps do something towards mitigating the evil of the free sitting system is made in a paragraph on page 441.

Mr. Arthur C. Banfield records his satisfaction in the long use of a 12 x 10 soft-focus lens for which only a few shillings was paid. (P. 455.)

Opportunities of discreet advertising, which occur in the social life of a town and in which a photographer can share, may often be profitably taken. (P. 442.)

A hint regarding the arrangement of groups, which have to be taken with a wide angle lens, is given in a paragraph on page 442.

In a leading article we give some advice on the choice of a camera which can be used effectively in the hand and at the same time serves the majority of the purposes for which a stand camera is used. (P. 442.)

In the storage of negatives in their original boxes the top negative of each box should be placed face down. Negatives in bags should be inserted with the film side facing the front of the bag: if placed facing the pasted seam markings are liable to appear in the course of time. (P. 454.)

A form of flash lamp, which includes provision for the collection of the smoke and adopts a wireless method of igniting the powder, is described in a recent patent specification. (P. 448.)

A correspondent draws attention to the damage recently done to moist negatives by insects. (P. 453.)

At the Croydon Camera Club last week the hon. secretary, Mr. J. M. Sellors, gave many useful hints on the art of lettering, and recommended inks and pens which in his long practice he had found satisfactory. (P. 450.)

EX CATHEDRA.

A South Light. In a recent examination, the following question was put: "How would you overcome the difficulty of lighting the sitter in a studio with a southern aspect?" Quite a number of students solved the problem by recommending that all light be blocked out and half-watt lamps installed. This is certainly an effective method, but during a great part of the year rather a wasteful one, not to speak of the healthful properties of daylight. The reply which it was intended to elicit was that every effort should be made to screen out all light not needed for producing the negative. This can best be effected by means of fairly large screens; ordinary backgrounds upon their stands answer very well, placed parallel with the side light, at such a distance as will not interfere with the lighting of the sitter, but will prevent a general glare and excess of reflection from the walls. It is advisable in such a studio to have very thin white curtains to cover all the glass during the period of sunshine. At other times they can be drawn out of the way, making this system superior to that of using ground glass or a stippling of paint.

* * *

Free-Sitting Reforming Itself. We are very glad to have heard expressions of approval by leading West-end portrait photographers of the paragraph in which we recently ridiculed the clumsy methods of some of those who are playing the free-sitting game. (B.J., June 23.) The thing which interests us particularly is that this approval comes from people who themselves offer a pretty fair number of free sittings. But they like to see the system worked intelligently, and, moreover, so we hear, they take the view that the time has come to do something in the way of setting certain limits to the practice of approaching people, offering to photograph them for nothing. They take the view—and we entirely agree with them, for it is a point which we have emphasised over and over again—that the broadcast canvassing of people belonging to certain classes of society is a stupid scheme, and one which is damaging to photographic portraiture as a whole, unless there exists a real and unquestionable demand by the illustrated Press for photographs of the people. In a very great number of cases no such demand exists; the canvassing photographer says that it does, simply by way of excusing his importunity. His actual motive is to wheedle an order out of the sitter after the sitting has been given. We are quite prepared to draw a distinction between the offer of a free sitting, which is prompted by a known demand on the part of the Press, and that which is only an underground dodge to obtain orders for portraits. Perhaps, by the exercise of a little casuistry, one may be called legitimate and the other illegitimate. At any rate, some progress would be made towards eliminating this objectionable feature from the

business of photographic portraiture, if some agreement could be come to for the discontinuance of the broadcast system by confining the invitations to people whose portraits may reasonably be regarded as in current demand by the newspapers. We realise that it is not easy to draw a line, but the distinction which we have made may, perhaps, supply a basis for discussion

* * *

Advertising. The photographer with a good-class business is often apt to look upon advertising as *infra dig.* There are, however, more ways of advertising than by paying for an insertion in the newspaper, and subtler methods are sometimes more effective in the long run and with certain classes of customers. It is often a paying proposition for a photographer to take an active part in the social life of his town. A subscription to the local musical or dramatic society is often worth while; still better is an active participation in their proceedings. Membership of the local literary, debating or archæological society, apart from the actual business it might bring in, is useful in keeping one's name before the public. Of course, one should take a little *real* interest in these subjects, and not go to a society meeting unequipped with the elements of knowledge of the subject under discussion; cultivated people, like a cobbler who does not stick *too* closely to his last (to use a homely metaphor). Attendance at book and fine-art sales, race meetings, cricket matches, etc., need not be too assiduous, but may prove useful.

* * *

Washing Economy. In these days of higher water charges it behoves every photographer to look to the efficiency of his washing appliances. The photographer, with his reputation to preserve, cannot afford to risk the permanency of his prints or negatives by insufficient washing, but many ways of washing are not only wasteful of water but very inefficient. The rapidity with which hypo can be eliminated from paper or gelatine depends on the rate with which fresh water is brought to the surface of the film and the contaminated water removed; the actual velocity of the stream greatly assisting the hypo to diffuse out. A thin stream of water in rapid motion, which passes over every part of the surface to be washed, would be more efficient than, *e.g.*, to place the prints at the bottom of a large vessel with a large quantity of water flowing in and out, the majority of which does not reach the paper. With these ideas in mind it would not be difficult for the photographer to examine the efficiency of his washing system and to improve it.

* * *

Wide-Angle Groups. The very unpleasant effect caused by the use of a wide angle lens for taking flashlight groups, whereby the faces near the lower corners are drawn out until they are almost unrecognisable, is due, not, as is often supposed, to any shortcoming in the lens, but to the laws of plane perspective. No optical device is capable of modifying it. Although this should be known to all photographers of any experience, such does not appear to be the case. We recently heard the effect attributed to astigmatism, the idea being that the faces were broadened by the same process as a disc is represented as an ellipse near the edge of the field of an astigmatic lens. This is, of course, a complete misconception, for the same thing will occur if a pinhole be used in place of a lens. The effect is not produced if a panoramic camera of the Al Vista or Cirkut types is used, but this cannot be done with flashlights, and, moreover, the perspective rendering of an interior with such a camera would be unacceptable. The best plan to adopt is to endeavour to group as many figures in the centre of the foreground and to leave as much as possible of the bottom corners of the plate as can be managed free from members of the group.

HAND AND STAND CAMERAS.

THE photographer who is contemplating the purchase of a small camera, say, a half-plate size, is often in doubt as to which model will be the most serviceable. If the expense be no object, then it is not advisable to endeavour to obtain all the desiderata in one instrument, but to procure separate ones for different classes of work. As this is, however, rarely the case, it may be profitable to review the capabilities of the various types of general purpose cameras now on the market. It will, perhaps, simplify matters if we assume that the immediate object is to secure a series of negatives suitable for postcard views, the subjects ranging from beach scenes to church interiors, comprising also architectural details, objects in the local museum, and the like. For most of these subjects the ordinary parallel-bellows camera would certainly be the most convenient, but the principles on which it is constructed are most unsuited for hand-camera work, so that it must be passed by. The conical-bellows field camera is not much better, as it is not usually built so as to be conveniently held and manipulated in the hand, and the setting up on a tripod for every subject is rather troublesome.

It appears, then, that a camera which is constructed with a view to being used in the hand, but possesses all the adjustments of the ordinary field camera, is most likely to give satisfaction. The prototype of all the current models was the "box-form" camera of George Hare, the first camera which was made commercially to close up with the lens and shutter *in situ*. As the lens was a rapid rectilinear projecting its full length from the front, and the shutter was a before-lens roller blind, the apparatus was somewhat clumsy, but the idea was sound, and shorter lens tubes and between-lens shutters made the way clear for such cameras as the Watson "Alpha," the "Sanderson," the "Sinclair Una," and the Dallmeyer "Correspondent." These and several other cameras have the following features in common: a lens and shutter permanently fixed to the camera front ready to be drawn out to an "infinity catch," nearer distances being focussed by rack and pinion; a double-extension bellows; a rising front and reversing and swing back. A focussing scale and finder are also provided. Moreover, some cameras of this type have also the "wide angle movement," which permits of the use of very short focus lenses without cutting off by the baseboard. Even if this movement is missing, it is not a serious defect, if both front and back of the camera are made to swing as they generally are. Besides the normal lens supplied with the camera it is possible to use both wide angle and long-focus or even a telephoto lens when needed, while the front lens-shutter may be supplemented or superseded by a focal-plane one, at the expense of a little extra weight and bulk.

Cameras made primarily for hand or "snapshot" exposures have more capabilities for stand work than their owners usually realise. A well-known humourist once wrote in gleeful terms of his discovery that his fountain pen was an extremely useful instrument when used in conjunction with an inkstand; and it may be said of a reflex camera that it serves well when used on a stand with the mirror and shutter out of action. There is the disadvantage of the absence of a swing back, and

a rather limited range of rise to the front, but even with these drawbacks much useful work can be done. With the mirror out of the way it is generally possible to fit a short focus lens in a sunk front, which adds considerably to the utility of the instrument. It is hardly necessary to point out that the tripod should be of sufficient strength and rigidity to support so heavy a camera. An aluminium tubular stand is not to be recommended for a reflex.

The collapsible or Anschütz type, while being more portable than the reflex, is better adapted for tripod work, for, except for the want of a swing back, it is capable of doing almost any class of work. As these cameras are usually fitted with very rapid lenses, they are suitable for home portraiture. It should be remembered that extension bodies permitting the use of long-focus lenses can be fitted to this type, although in most cases a Telecentric or similar telephoto lens, which gives double the equivalent focal length at the normal extension will be found the most convenient. With either this type of camera or any other which is provided with a focal-plane shutter, it is advisable to use a cap for time exposures, unless the tripod is unusually rigid.

Roll film and magazine cameras which have no focussing screens, can, of course, be used upon a tripod, but the difficulty of insuring exact agreement between the image in the finder and that upon the film, especially when the rising front has to be used, rather takes them out of the class of hand and stand cameras. To work with any degree of certainty a plate attachment with a focussing screen should be fitted when the Kodak becomes virtually an ordinary camera.

There are many folding cameras in which the back is supported by slotted bars which are held at a fixed point by a spring; it is usually quite possible to fit one or both struts with a clamping screw, so that a swing-back movement can be obtained.

In selecting a hand-and-stand camera, great care should be taken to obtain one which has a very solidly constructed front. Thin single metal supports cannot be relied upon to keep true, and when this is no longer the case, the working of a rapid lens is seriously handicapped. For use in the hand as a direct-vision finder, either a wire frame or a concave lens will be found more convenient than the usual brilliant or ground glass finder with a mirror; the experience of Press photographers has proved that the eye-level position is the most practical one.

THE QUANTUM THEORY OF PHOTOGRAPHIC EXPOSURE: A CRITICISM.

(A communication from the British Photographic Research Association.)

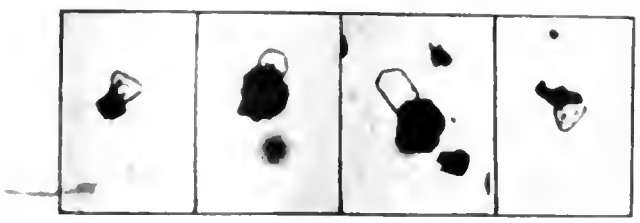
Two very interesting papers have recently been published in the "Phil. Mag." dealing with a light-quantum theory of photographic exposure. The theoretical side of the question has been exhaustively studied by Silberstein, and Trivelli and Righter claim that preliminary experiments by them support the theory to a pronounced degree. It is not necessary to quote details as to the theory—it has already been put forward in a more or less popular way by Silberstein and Mees in a recent issue of this Journal ("B.J.," 1922, June 30, pp. 384-387). The equation derived by Silberstein, which, he says, under the conditions prevailing in all practicable experimental cases, is of more than sufficient mathematical accuracy, is

$$k = N(1 - e^{-an}),$$

where a = area of the grain,
k = number of grains hit,
N = total number of grains per unit area,
n = number of light-quanta impinging upon unit area.

Any new advances in knowledge are open to criticism, and such criticism is now given of the papers in question. Trivelli and Righter state that they are able to test Silberstein's formula connecting the fraction changed with the area of the grain very severely by using not only single grains of different sizes, but also clumps of any number of grains up to as many as 33 in a clump. They claim that this is permissible *because grains when clumped together act as one grain for development to the limit*. They consider as untrue Slade and Higson's statement that "One grain which has become developable is unable to make a grain, situated in close proximity to it developable, unless the latter grain is developable in itself." In the paper by Mees and Silberstein it is apparently admitted that the brilliant experiments of Svedberg's have definitely proved that Slade and Higson's statement is correct in the case of small spherical grains. Mees and Silberstein merely suggest this is due to the fact that these very small grains are not in such close contact as the larger flat ones.

On what is this statement of Trivelli and Righter based? In their paper they give the results of their experiments, which, it is claimed, show that within a given emulsion, exposed and developed, the percentage of clumps of grains which are changed increases with the area of the clump. They say that "from the table it is readily seen that this statement (of Slade and Higson) is not true." It is difficult to see how this is proved by the experimental results; in fact, it will be shown later that these are just the kind of results to be expected if Slade and Higson's statement *is true*. In any case, if Trivelli and Righter's statements are correct, it should be impossible in an emulsion containing large flat grains ever to find a case in which, of two or more grains in contact, only



one of them is developed, when development is carried to the limit. As a matter of fact, it is possible to show hundreds of such cases—and a few examples are given in the figure. Of course, it is not believed that these grains are ever in real optical contact; if they were, they would, naturally enough, act as a single grain. The conditions in the emulsion are such that they are almost sure to be separated by a fine film of gelatine. But there is no reason why the grains in Trivelli and Righter's experiments should be closer in contact than they are in the cases shown here, since both diluted emulsions were made in a similar manner. It will be seen from the figure that both the developed and the undeveloped grains are quite sharply in focus and since the magnification is about

2,000, they must be very near together. It seems very improbable that these differences are due simply to the different emulsions used, since they are both of the same type, i.e., flat grains. It would be interesting to know if Trivelli and Righter have ever examined their emulsion before de-silvering, and found it impossible to observe a single case of a developed and undeveloped grain together. This seems the most natural thing to do, but there is no reference to such an experiment in their paper.

Silberstein states that "the chief and most immediate consequence of the proposed theory is the essential dependence of the proportionate number of grains affected, k/N, on the size a of the grain, i.e., according to the equation

$$k/N = 1 - e^{-na}$$

$$\text{or } \log\left(\frac{N}{N-k}\right) = na.$$

Now n is the number of light-quanta impinging on the plate, and is therefore constant for a given exposure. The first obvious test of this equation is to take the case of sets of single grains (so as to avoid the question of clumping altogether), and to measure accurately every grain counted. Considering two sizes of grain, say a_1 and a_2, with number changed k_1 and k_2 respectively, we shall have

$$\log\left(\frac{N}{N-k_1}\right) = n.a_1.$$

$$\text{and } \log\left(\frac{N}{N-k_2}\right) = n.a_2$$

$$\text{or denoting } \log\left(\frac{N}{N-k_1}\right) \text{ by } A_1 \text{ and } \log\left(\frac{N}{N-k_2}\right) \text{ by } A_2,$$

$$A_1/A_2 = a_1/a_2$$

i.e., the ratio of A_1/A_2 is independent of the exposure. This experiment has already been carried out in our laboratories, and the results, which are to be published in the "Phil. Mag." (in the press), show that this relation does not hold, and that A_1/A_2 varies enormously with the exposure. It is shown there how easily this can be explained on the basis of the existence in the grains of specially light-sensitive points. Silberstein states that the fact "that out of a number of apparently equal grains subjected to a sufficiently weak exposure one or two are affected, while the others—nay, their next neighbours—remain perfectly intact," is a tangible proof of the correctness of the assumption of spatially discrete as against continuous (light) action. He even says: "It would be in vain to ascribe to these survivors a greater immunity or indifference to light." It is difficult to see any justification for such a statement as this; surely when two grains act differently under the influence of light, the first and most natural assumption of all is that the grains themselves are different; from the chemical point of view there is no reason why this should not be the case.

Trivelli and Righter's experimental method is, apparently, as follows:—In the single-layer emulsion which they prepare, the grains, which are of varying sizes, are sometimes found clumped together in groups. This emulsion is exposed to a certain intensity, developed, and before any examination is made the silver is dissolved out by means of a de-silvering solution. The counting of the number of clumps of various sizes in a given area is then carried out microscopically, and the percentage of clumps of each size which are changed is determined in the same manner as by Svedberg. The authors find that the percentage of clumps changed increases with the size of the clump.

Now it is not difficult to see that this result would also be obtained if a clump did *not* act as one grain, *i.e.*, if each grain which is changed to silver is developable in itself, as stated by Slade and Higson. For simplicity consider only grains of one definite size, and let there be, say, 70 per cent. of the single grains unchanged, or 30 per cent. developed. Then of every 100 single grains which are examined 70 will be unchanged, no matter what is the size of the clump in which they are. Thus to find the percentage of clumps of two which are changed, we have the familiar probability problem of finding the chance of drawing two white balls (unchanged grains) from a bag containing 70 white balls and 30 black (developed grains), the balls being drawn in pairs. This can be shown to be equal to 0.488. Thus the percentage of clumps of two which still remain as two unchanged grains after exposure is 48.8. If the plate had been de-silverised, so that there were no clumps of 1 changed and 1 unchanged, or two changed, and if there were no clumps of more than two grains, then the percentage of clumps of 2 changed would be counted as $100 - 48.8 = 51.2$, as against 30 for the single grains. Similarly, a larger percentage still would be obtained for clumps of three.

If each grain changed must be developable in itself, the process of de-silvering introduces a serious error. Thus, for example, in counting the number of unchanged singles in the exposed portion, what is really counted is the number of grains which were singles all the time, plus clumps of two of which one has been changed, plus clumps of three of which two have been changed, and so on. Thus the number of undeveloped *singles*, as determined by counting, is really too large or the percentage changed too small.

It would be very interesting if Trivelli and Righter carried out an experiment with grains of one size only without dissolving away the silver—counting the percentage of clumps of two having two, one and zero unchanged grains. It is ventured to predict that their results would fit in with simple probability calculations like that shown here. Unfortunately, one cannot test in this way the numbers given in their table, because the grain size is not constant for all sizes of clumps.

As yet, it is impossible to accept the experimental evidence as strongly supporting Silberstein's theory. In the paper in this Journal three tables are given, and the authors state that the experimental and theoretical results "agree admirably." This is a matter of opinion. It seems very optimistic to say that such pairs of values as 76.6 and 68.9, 21 and 28.2, 87.5 and 81, 25 and 38, 56 and 66, 63 and 82, 68 and 86, 76 and 89 show admirable agreement.

A Market for Photographs.—On a recent occasion we had the pleasure of renewing our acquaintance with Mr. Franklin L. Fisher, chief of the illustrations division of perhaps the most important illustrated journal, namely, the "National Geographic Magazine," published in Washington, by the National Geographic Society. Mr. Fisher was upon one of his periodical visits to Europe, gathering photographic illustrations for the use of his magazine, and he left with us a copy of a booklet which has been produced for the guidance and information of photographers able to supply some of the many and varied demands of the "National Geographic Magazine" for photographic illustrations. It is of interest to note that within the last few years the National Geographic Society, by adopting the policy of making its journal of popular interest, largely by the lavish use of photographs, has increased its membership to 700,000, and may well claim to be the largest educational association in the world. Although following many other activities, its "Magazine," with a circulation of nearly three-quarters of a million, occupies a large place in its programme, and no pains are spared to add to the attractiveness of its pages by the selection of choice photographs, and by the finest engraving and printing. The editor of the magazine uses approximately 2,000 photographs per annum, and a fair number of Autochromes which are reproduced in colours. The booklet to which we have referred fully describes the classes of subject, the technical qualities which recommend photographs for use in the magazine, terms of payment, etc. Photographers throughout the world are invited to send for this publication, which is obtainable free on application to the National Geographic Magazine, 16th and M. Streets, N.W., Washington, D.C., U.S.A. The booklet gives the fullest particulars, and is illustrated by some dozen large reproductions of photographs (from all parts of the world) of a kind which are suitable.

NOTES ON THE FOCAL-PLANE SHUTTER.

[In an article recently published in "American Photography" the author, Mr. Charles T. Jacobs, usefully draws attention to some of the properties of the focal-plane shutter which are often neglected, in particular to the variability of its efficiency, chiefly according to the width of the slit and the distance of the latter from the plate. Inasmuch as greater efficiency can often be secured in practice by working with a wider slit and a higher spring tension instead of with a narrower slit and a lower tension, what he has to say on this subject is deserving of a careful reading. We, therefore, reprint his paper, although we cannot altogether agree with his unqualified advocacy of the focal-plane shutter, for we think that he does not take a sufficiently serious view of its more complicated construction and liability to derangement as compared with a between-lens shutter. In cold climates, also, the stiffness of the blind which results from a low temperature is a very practical drawback.]

The writer has often been surprised at the general lack of familiarity with the focal-plane shutter. Many have only very vague ideas as to its construction and operation, while others are totally unaware of the existence of a shutter radically different in design from the usual between-lens type. This is an extremely unfortunate condition, as the focal-plane shutter has several undeniable advantages over the lens shutter, and doubtless many who would otherwise invest in and use one fail to do so simply through ignorance or a misimpression of this shutter.

Among the points of general superiority of the focal-plane shutter are its greater speed and greater efficiency, as well as the possibility of changing the lenses on the camera without the necessity of a separate shutter for each lens, owing to the fact that the focal-plane shutter is built into the camera, not the lens mount. A less general advantage, but an immense one nevertheless, is its adaptability to the reflecting camera—indeed, it has made possible that instrument as we know it to-day.

Of course, there have been arguments brought forward against the use of the focal-plane shutter. Among the objections to its use, we hear that it takes more space, necessitating a larger instrument, that it distorts, and that it is not as simple in construction or operation as the lens shutter. As for the first, focal-plane shutters are fitted to small cameras, so that it can hardly be argued that this point is a very serious one. Regarding the second, it is quite true that the shutter distorts on occasions where there is extremely rapid motion of the subject. But in cases where this is really noticeable the subject will be found to be one beyond the capacity of the between-lens shutter, and surely a slightly distorted image is to be preferred to none at all. Finally, the claim that the shutter is more complex in construction and operation than the lens shutter, while possibly true to a limited extent, is robbed of its formidability once one grasps the underlying principle of the instrument, which is really simpler than that of the between-lens type.

The focal-plane shutter is not placed anywhere near the lens, but instead is operated just in front of the plate, which lies in the focal plane of the lens—hence the name given the shutter. It is merely an opaque blind running between two rollers, one above and one below the plate (in a few models one on either side). The blind is wider than the plate, and its edges run in grooves so that no light can creep around. In the blind are one or more crosswise slits, each as long as the plate is wide. Normally no slit lies in front of the plate, the blind here being unbroken, and acting as does the slide of a plate-holder in protecting the plate from the light admitted by the lens. When the shutter is released, however, the blind is moved at high speed from one roller to the other, far enough for one of the slits to pass in front of the plate, momentarily admitting to it the light from the lens, thus making the exposure.

Consideration will reveal that the exposure of the plate is not the time elapsing between the starting and stopping of the blind, but rather the length of time any one point is uncovered. This time depends on two factors—the speed with which the blind travels and the width of the slit. The former is governed by the tension under which the pulling roller (usually the lower) is held. This is usually adjustable, but on some models is automatically taken care of. The second factor—the width of the slit—is, of course, a variable one. There are two ways of obtaining this variation—the use of a blind with several slits each of different width, and the use of one with a single slit of adjustable width.

The first of these two types is the simpler of the two, but requires a longer blind, as between each slit and the next there must be enough solid curtain to cover the plate. The mechanism is so arranged that only one slit passes in front of the plate when the shutter is released. After one exposure the instrument is ready for an exposure with the next wider slit. Should a still wider slit be required, the shutter must be released, the plate being protected while this is being done. On the other hand, should it be desired to use the original slit again, the blind must be wound back one slit—or if a still narrower slit is wanted, still further. This re-winding is done by a key on the outside of the instrument, and while it is being done (as well as when the shutter is being released for purposes of setting as mentioned above) the plate must be protected from the lens. In a reflex camera this is easily done by means of the mirror. In any other camera, however, the slide must be inserted in the plate-holder, or the lens capped.

The second type of blind, though a little more complex in construction, is possibly a trifle simpler in operation. It is made in two parts, so arranged that the distance between them is variable. This variable space constitutes the exposure slit, and its width is adjustable from a very narrow opening to the full height of the plate. The shutter must be rewound after each exposure, the distance the key is turned in re-winding usually governing the width of the slit. On many models it is possible, without releasing the shutter, to alter the width of the slit, in one direction at least, after the shutter has once been wound. This is a great convenience in cases where it is found that the subject to be photographed calls for a different exposure than that for which the shutter has already been set. Some shutters with this type of blind are known as "self-capping." That is, the two parts of the blind are made to overlap while re-winding is going on, thus obviating the necessity of protecting the plate in any other way. This is a particular advantage on cameras other than reflexes, as they have no mirror which can be conveniently used for protection of the plate.

The range of instantaneous speeds obtainable with the focal plane shutter is from about one-tenth of a second to one one-thousandth of a second on most models. Besides these speeds, time exposures are possible with either type of blind. The largest slit in either case is as wide as the height of the plate, and can be stopped in front of it. This permits focussing at the back of the camera, as well as time exposures of any duration, which latter can be terminated by simply releasing the shutter. Bulb exposures are usually possible as well—i.e., the largest opening can be brought in front of the plate by pressing on the release, and it will remain there until the pressure on the release is terminated. An automatic adaptation of the bulb exposure is often included, by which exposures in the neighbourhood of one-fifth of a second to a whole second are obtainable.

The way in which the exposure obtained at any setting of the shutter is indicated varies on different instruments. In some cases (usually where there is no external tension adjustment) the exposure is indicated directly at the key, or is automatically registered nearby. In, probably, most cases,

however, a table is supplied with the shutter, usually attached to the camera, showing the exposure obtained with any combination of blind slit and tension. A little examination of a table of this kind shows that in many cases the same exposure can be obtained with one tension and slit as results from the use of a higher tension and wider slit. The natural inference is that the two are equivalent in every respect, and hence that there is no preference, in theory, as to which is used. This is not strictly so, as this brings in a question of the efficiency of the shutter, which is greater in some cases than in others. Naturally, it is desirable to understand this subject so that the shutter can be used at greatest efficiency, particularly when light conditions are bad and motion of the subject exists.

The efficiency of a shutter at any exposure is the ratio of (*a*) the amount of light actually admitted to the plate to (*b*) the amount which would be admitted were the lens fully uncovered as long as it is uncovered at all. Thus in the lens shutter, where a good portion of the time of exposure is consumed in the opening and closing of the leaves, the efficiency is poor, falling to less than one-half—or 50 per cent.—in many cases. The efficiency of the focal-plane shutter, on the other hand, is usually quite high. It is often argued that, owing to its peculiar construction, it is really 100 per cent. efficient. This is not so, as to fulfil this desirable condition the plane of the blind would have to coincide with that of the plate—a manifest physical impossibility. Usually the blind sets about $\frac{3}{8}$ of an inch, or one centimetre, away from the plate. On some film cameras fitted with the focal-plane shutter this distance is reduced to $\frac{1}{8}$ of an inch—a decided improvement. On the other hand, it is often greater than $\frac{3}{8}$ of an inch, a condition not to be desired, as the nearer the blind is brought to the plate the greater will be the efficiency of the shutter, other conditions being equal.

To get a rational idea of the light-action on the plate when the focal-plane shutter is used, an individual point on the plate must be considered. As the blind is operated (let us assume downward, as is usually the case), the first direct ray of light from the lens is received by any point just as the lower edge of the slit passes the imaginary line between the point and the top of the lens. A tiny space of time elapses before this edge lines up between the point and the bottom of the lens, and during this time the lens is being uncovered to the point. For a time, then, the lens acts fully on the point. Then the top of the slit comes in line between the point and the top of the lens, and as the blind continues to move the lens is covered, so far as the point is concerned, from the top downward. So even in the focal-plane shutter some time is consumed in uncovering and covering the lens—considered from the position of a single point on the plate. As all the points on the plate receive the same exposure, this is true for the whole plate. The time is usually but a very small portion of the total exposure, however, and so it is rarely that the efficiency of the focal-plane shutter drops to the neighbourhood of that of the lens shutter.

Focal-plane efficiency depends on three factors: viz., lens aperture used, width of slit employed, and distance of blind from plate. If the first is expressed by its *f* number, and the second and third in the same units ($\frac{1}{8}$ inch is preferable to 1 inch in the English system, as it avoids fractions), it can be shown that if the shutter speed is uniform:

$$\text{Efficiency} = \frac{\text{Lens aperture} \times \text{Width of slit}}{(\text{Lens aperture} \times \text{Width of slit}) + \text{Blind distance}}$$

From this it may be seen that the efficiency of the same instrument depends only on the product of the lens aperture and shutter slit employed, as blind distance is constant. It is merely necessary to divide this product by itself plus the blind distance, and the efficiency is obtained, expressed as a fraction. It can be obtained in per cent. by multiplying this result by 100. It is absolutely necessary, however, that in using this formula the lens aperture be considered by its *f* number, and the shutter slit and blind distance be measured in the same unit. The accuracy of the figure obtained will depend, of course, on how near an even speed is maintained by the blind throughout the exposure. In modern instruments the variation in speed in the same exposure is very slight, owing to the perfection which the shutters have attained.

Speed work is the particular field in which efficiency is important. The reason is two-fold. First, the exposures which can be given are so short, owing to motion of the subject, that under-exposure is bound to result, making it desirable to get the maximum light-action on the plate in the time available. Secondly, the short exposure, with its narrow slit, and the wide aperture which must be used in the lens, are the very conditions under which the efficiency of the focal-plane shutter drops badly. There is one thing which can be done, however, to increase efficiency—use the highest tension the instrument affords, as this will permit a wider shutter slit without increasing the length of exposure. On instruments where there is no tension adjustment for the operator to use, it will be found that at the lower slit widths the tension automatically increases. Incidentally it might be mentioned that the high tension will help to minimise the distortion produced by this shutter, mention of which was made above.

In cases, however, where efficiency is fairly high in any event—i.e., on the longer exposures with smaller apertures of the lens—it may be advisable to use a lower tension, as higher ones are certainly harder on the mechanism of the instrument. The difference in efficiency caused in a case of this kind by halving or even quartering the shutter slit to compensate for the decreased tension is not sufficient to be of great account. It is only as the faster exposures and wider apertures are used that it behoves the user of the focal-plane shutter to concern himself with the efficiency of his instrument, which is very high in all other cases.

There is one penchant of the focal-plane user which certainly operates to his disadvantage in many cases—the mania for the use of a high speed when it is not necessary. Some people are so obsessed with the idea that the focal-plane shutter is nothing but a speed instrument that they use the higher speeds all the time. Nothing is more ridiculous, especially in cases where the rendering of the subject would be improved by the use of a smaller lens aperture and correspondingly longer exposure. Under-exposure often results from this practice of using the faster exposures, not only because it is often carried so far that correct exposure cannot possibly result, but also because the varying efficiency of the focal-plane shutter at different settings upsets the equivalence of different combinations of lens apertures and exposures. Thus, though 1-50 of a second at *f*/16 and 1-400 of a second at *f*/5.6 are theoretically the same, the latter setting with the focal-plane shutter would not admit as much light as the former, owing to considerably decreased efficiency.

Because of its high efficiency at the slower exposures, even when used with a wide aperture at the lens, the focal-plane shutter is a fine instrument for photography where the light is poor, and when with the ordinary shutter an instantaneous exposure is precluded. This feature of its use is often overlooked by those who consider it first, last and always a speed instrument.

It is hoped that more people will be brought to realise that in the focal-plane shutter they have an instrument which, with almost no exception, will do all that the lens shutter will, and a lot besides—an instrument not built for one single class of work, but for all conditions—and an instrument which is flexible enough to do them all justice.

CHAS. T. JACOBS.

NEW SPANISH CUSTOMS TARIFF.—Several important changes are notified in the New Spanish Customs tariff. Those affecting the photographic trade are:—Hand photographic apparatus up to 13 x 18 cm. and stereoscopic apparatus of any size, 10 pes. per kileg. Photographic apparatus for the studio, and hand photographic apparatus 13 x 18 cm. or *larger* (both without objectives), stereoscopes, cinematographs with their parts and photographic accessories, such as amplifiers, projection apparatus, *wooden or metal frames*, tripods and the like, 1 pes. per kilog.

RECOVERY OF SILVER FROM FIXING BATHS, ETC.

In the current issue of the "Journal of the Society of Chemical Industry," Mr. E. Gardner has a note on the recovery of silver from photographic waste solutions and also from those used in the glass-silvering and electro-plating trades. The following is the portion of the communication which deals with photographic solutions. It will be seen that Mr. Gardner recommends clean scrap iron for the reduction of silver in preference to the commonly used "liver of sulphur."

Comparatively large quantities of silver, gold, and platinum are used in photography, glass-silvering and chemical gilding, electro-plating and other industries, but relatively very small amounts are recovered from spent solutions owing to ignorance of simple and cheap methods of recovery. In the first three trades mentioned above, over 2 million ounces of silver nitrate, worth £200,000, is consumed yearly in Great Britain; of this amount more than three-quarters is used in photography and most of the silver content is lost irretrievably.

The spent solutions produced by the photographer comprise toning-baths, fixing-baths, and various washing waters. Taking an average print on self-toning paper, about 85 per cent. of the silver originally present goes into the preliminary wash-water and fixing baths, 5—8 per cent. remains in the print, and the remainder passes away in the final washing.

Of the methods of recovery recommended in text-books on photography, precipitation of silver from fixing-baths and wash waters by means of "liver of sulphur" does not produce a precipitate that settles well, and contamination with polysulphide, or any sulphides, is to be avoided where photographic materials

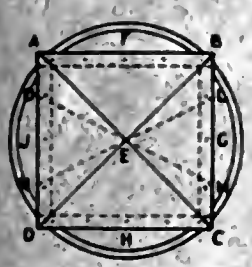

Fig. 1.—Top view of filter.

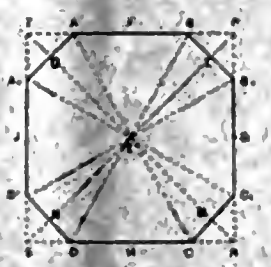

Fig. 2.—Filter cloth removed from frame, showing folds.

are used. Precipitation of gold from toning-baths by ferrous sulphate is not satisfactory for cold and very dilute solutions, especially when thiocyanates are present; and there are much better reducing agents than ferrous oxalate for precipitating platinum.

The method recommended by the writer is to collect all solutions in a wooden vessel and to precipitate with clean scrap iron. Reduction is complete within 24 hours, heating is unnecessary, and the precipitate settles very satisfactorily. Two wooden casks should be used for continuous photographic work, one being used for charging and precipitating while the precipitate is settling in the other. The clear liquid is siphoned off.

At the yearly clean-up the precipitate is passed with water through a coarse sieve (6 holes to the linear inch) to separate undissolved iron, drained on a calico filter, washed with hot water, placed with the cloth in an enamel dish, and dried at a gentle heat. The precipitate should not be dried completely otherwise it may ignite spontaneously. It consists of impure metallic silver and possibly gold and platinum, and is technically termed "foots," an Anglo-Saxon word meaning the dregs or lees settling from a liquor. The operation of obtaining the precipitate may be called "footing."

The precious metals in paper cuttings, spoiled prints, etc., may be recovered by incinerating the material, if necessary after moistening with a solution of alkali nitrate, and adding it to the footing cask. Great care is required in burning celluloid films. Spoiled plates should be fixed, but negatives are not worth stripping. Batches of spoiled emulsion should be liquefied in warm water and treated with scrap iron in a separate cask, as they are very rich in silver. It is recommended that the collected precipitates be sent direct to a refinery; it is useless to send dilute solutions to a refinery as the freight on these will leave no margin of profit.

A few instructions on the making of square calico filters for these precipitates may be of use.

A square wooden frame is made of such size that its corners will just rest on the edge of the deep circular vessel into which it is proposed to filter. The frame may be, for example, 14 in. square and 3 in. deep and made of batten 1 in. thick, thus leaving an inner opening of 12 in. square.

From a piece of new, closely woven calico, washed to remove dressing and dried, cut an exact square of 24 in. side, mark the middle of each side and the middle of each upper edge of the frame, which may be conveniently standing on the circular vessel (Fig. 1). Taking the middle of each cloth-edge in turn, and doubling ½ in. underneath to strengthen it, fasten it temporarily by means of copper tacks to the middle-points, F, G, H, J, of the upper edges of the frame, leaving the slack of the cloth hanging inside.

On the side A B, draw the cloth-edge tight from its central tack, double ½ in. underneath as before, and fasten it with a tack almost at the corner B; repeat this with the other half of the same edge towards corner A. Turn the frame round and deal similarliy with side C D. These two sides are now finished and are represented in the diagram of the unfolded cloth taken from the frame by the same letters (Fig. 2).

Taking side B C, hold the cloth-edge in one hand at a point B_1 (Fig. 2), 6.5 in. from the central tack, double ½ in. underneath as before, slightly raise it from the frame, and with the other hand fold neatly along the line E P. Bring the point B_1 exactly down to the corner B of the frame and fasten it there with a tack; treat the similar points C_1, D_1, and A_1 in the same way.

The cloth ought now to form a perfectly regular inverted pyramid inside the frame, and if not, some slight adjustment must be made. Each side will consist of one layer of cloth, but underneath the smaller triangles EBL, EMC, EDN, and EOA, in Fig. 1 there will be two extra layers. Drive the tacks home, add a few extra ones, and trim off the four ears of cloth which project beyond the frame (the triangles AA_1T, BB_1P, CC_1R, and DD_1S in Fig. 2).

The filter is now ready for use. Some boiling water is first passed through. Then a little precipitate is put in to form a filter bed, and as soon as the filtrate runs clear the filtration is proceeded with, care being taken that the filter does not run dry before all the precipitate is placed on the cloth. Finally, remove the soluble salts by washing a few times with hot water.

In packing precipitates before sending them to a refinery, care should be taken not to use metal boxes. A precipitate like moist silver chloride rapidly attacks iron or zinc, and foots powders often retain sufficient acid to corrode a metallic container. Well-made wooden boxes or jars of glass or earthenware should be used.

E. GARDNER.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

Patent News.

Process patents applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, July 10 to 15:—

DEVELOPMENT.—No. 19,442. Device for developing, washing and finishing photographic films and prints. S. H. Morse.

REPRODUCTION PROCESS.—No. 19,515. Photographic reproduction process. E. Doelker.

TELEGRAPHIC TRANSMISSION.—No. 19,205. Transmission of photographic images. P. and U. Ellero.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

LANTERN CONDENSERS.—No. 179,849. (June 24, 1921.) Fig. 1 is a diagram representing an ordinary condenser with its source of light and the course of the light; and fig. 2 is a similar diagram of a condenser according to the invention.

In fig. 2 the first two lenses c and *d*, located at the end of the condenser adjacent to the source of light *q*, are converging menisci presenting to the source of light concave surfaces of such curvatures that the rays of light incident thereon from the source *q* (which is, as shown, in close proximity to the lens c) are, owing to the gradual increase of the angle of incidence from the optical axis outwards, partly reflected to such a degree as to counter-

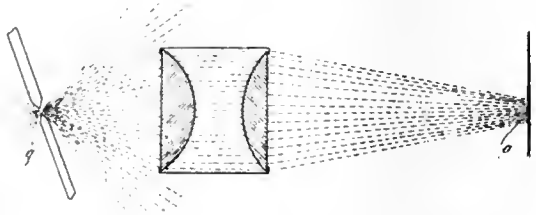

Fig. 1.

balance the diminution of absorption of light due to decreasing lens thickness with increasing distance from the optical axis. The first lens c is placed as near to the source *q* as practically allowed by the dimensions of the condenser. Theoretically the focal-length of the condenser might be so small that the lens would be in contact with the source of light, but practically it has been found that a focal-length as small as 11 millimetres may be employed, so that the condenser may be used with the lens c very close to the source of light.

The third and fourth lenses e and *f* are plano-convex lenses, whose convex surfaces are arranged to face each other.

By the second lens *d* the rays are directed substantially parallelly upon the third lens e, and the result is that a practically

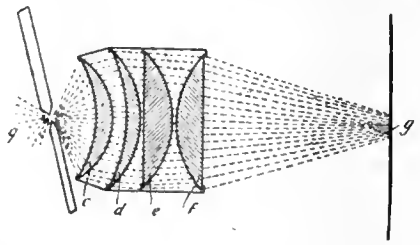

Fig. 2.

uniform pencil of rays is directed to the window *g* of the apparatus by the lenses e and *f*.

The following are dimensional particulars of a condenser made according to the invention; the focal length of the lens c is 230 mm., that of the lens *d* 300 mm., that of the lens e 180 mm., that of the lens *f* 180—450 mm., according to the focal length desired for the condenser; the radii of curvature of the concave surfaces of the lenses c and *d* are 120 and 135 mm. respectively; whilst the distances apart of the margins of the lenses c and *d*, *d* and e, and e and *f* are 28, 34, and 37 mm. respectively.—Kurt Morsbach, 12 Kloste: Strasse, Bad Oeynhausen, Germany.

FLASHLAMPS AND IGNITION.—No. 176,468 (December 1, 1920). The lamp casing *a* which may be of box-like formation and provided with a glass front a^2, is mounted at the upper end of a pair of telescopic tubular members *b* b^1. Preferably the lamp casing *a* is made to contain a pair of troughs c c^1 (for the magnesium) both of which are provided with adjustable covers *d* d^1, so that one only can be used at a time. The two covers *d* d^1 are formed back to back and turn about a common pivot pin e and the connecting arms thereon are adapted to co-operate with pairs of contact fingers *f* f^1 to make the required connection for the particular tray in use. At a suitable position in the case *a* is an opening a^1 which is covered by wire netting *g* enclosing a smoke-proof cloth or screen g^1 to blow out or

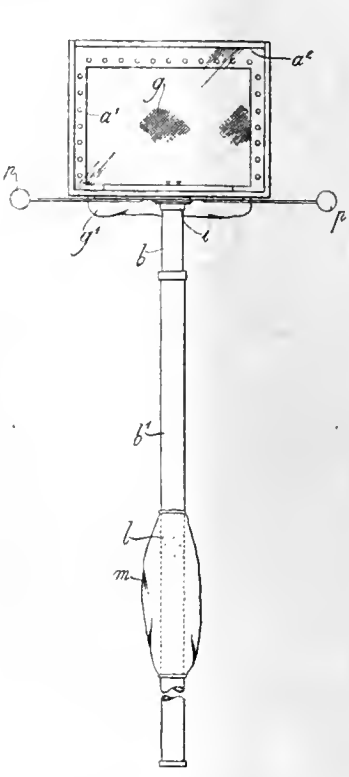

Fig. 1.

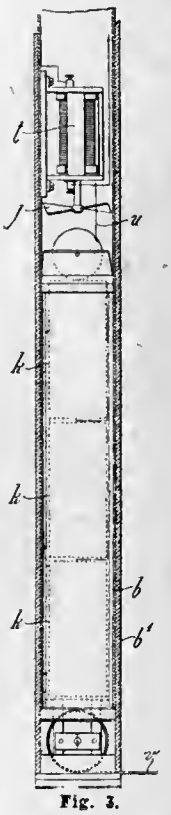

Fig. 3.

receive and thereby permit of the escape of the pressure of gas caused by the ignition.

At the upper end of the lamp casing *a* is a mica flap valve *h* adapted to be closed by the pressure from within, but to be normally open to admit of the ingress of fresh air. The telescopic tubes *b* b^1 are connected to the lamp box *a* at *i*, and within one of the tubes is arranged an electric fan *j* and one or more storage batteries *k k k* adapted to actuate it and also to provide the necessary E.M.F. to ignite the charges of magnesium. As the batteries *k* are arranged in the lower tube b^1 and the motor in the upper of the tubes, adjustable electrical connection is made by means of a coiled tape *u* wound on a spring drum after the manner of a flexible measuring tape, the other battery contact being likewise connected to earth.

At the lower end of the telescopic tubes *b* b^1 are provided a series of perforations *l* enclosed by a filtering cloth *m*. The arrangement of the magnesium trays c c^1 is such that the lids or covers *d* d^1 thereof are adapted to control the electric circuits; that is to say, the opening of one lid d^1 of the trough c^1 will connect up the circuits of that particular trough, whilst the closing of the other lid *d* will cut out those of the other trough c.

For controlling the passage of current through this circuit there are (in connection with a wireless coherer *n* or other detector and

a pair of capacities *p* adapted to receive from the wireless actuating apparatus), a relay *q* and batteries *o* and an earthed circuit, the latter of which is adapted to be closed by the relay. The arrangement is such that the coherer *n* is only adapted to actuate the relay *q* and permit the passage of current from the battery circuit *r* to fire the magnesium when the capacities *p* and the coherer *n* are in use.

In operation, two charges are placed in position, one in each of the troughs c c^1 and the lid of one of the troughs is closed, leaving the other open and in open circuit with the batteries *k*

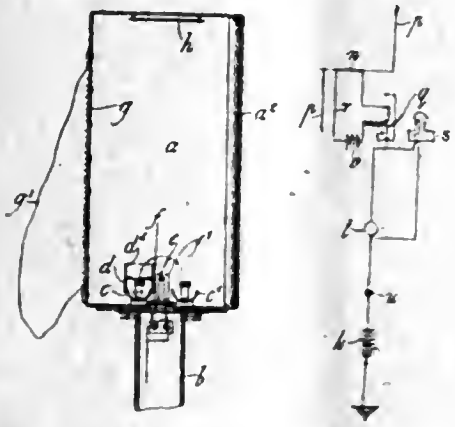

Fig. 2.

Fig. 3.

and the electric fan *j* (fig. 5). Wireless waves are then transmitted and picked up by the capacities *p* and acting on the coherer *n* close the relay *q* and permit the passage of the current and the ignition of the magnesium by means of the fuse wire *s*.

As soon as the fuse wire has burnt out the current then passes through the motor circuit. The excess of gas under pressure generated by the ignition is permitted to escape into the loose bag g^1 through the opening a^1 in the lamp box *a* at the same time serving to close the flap valve *h*. The gas under pressure then also escapes down the hollow telescopic tubular support *b* b^1, initially sets in motion the fan *j* of the electric motor if the current has not already started it, by acting on its blades, and then passes out by way of the perforations *l* and the

Fig. 4.

smoke-proof cloth *m* at the lower end thereof. The motor *t* is then kept in operation for a sufficient length of time to completely exhaust the lamp box *a* of the fumes and smoke and to draw in fresh air by way of the flap valve *h*. When this operation is completed the apparatus is then in order for the firing of the second charge and the operation is repeated if desired.

In order to facilitate the resetting of the fuse wire in the troughs c c^1 the wire *s* may conveniently be secured in transverse or diametral slits provided in the lower ends thereof, which are also chamfered or tapered in planes at right angles to these slits so as to prevent cutting of the wire.

It will be understood that the radio-energy received by the plates or other capacities *p* can be adjusted by means of suitable indications, condensers, amplifying valves, etc., and that the lamp case itself can, if necessary, be used for receiving the energy. As an alternative method one aerial can be erected on each lamp and the return circuit made by means of the coiled metal tape *v* arranged in the lower tubular supporting member and which may also be earthed to the transmitter by the same means.—Bertram Tom Hewson, 5, Oxford Terrace, Hyde Park, London, W.2.

The following complete specifications are open to public inspection before acceptance:—

Colour Photography.—No. 182,814. Photographic apparatus for making photographs in natural colours. H. Diernnofer.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Kima.—No. 424,732. Scientific instruments included in class 8. W. Watson & Sons, Ltd., 313, High Holborn, London, W.C.1, manufacturing opticians. March 27, 1922.

Oso.—No 424,837. Photographic paper, photographic albums, and photographic mounts, included in class 39. Thomas Illingworth & Co., Ltd., Cumberland Avenue, Park Royal, Willesden Junction, London, N.W.10, manufacturers. March 30, 1922.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

Stands Above All (Stork Design).—No. 421,936. Photographic apparatus included in class 8, made in Great Britain. William Butcher & Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4, manufacturers.

New Books.

Process Engraving. By Edward S. Pilsworth. New York Macmillan's. 2 dollars. 8vo. pp. 168.

The literature on the subject of photo-engraving is by no means so extensive that the appearance of another volume dealing with the subject on general and practical lines would not be welcomed. The present book gives an idea of American practice rather than the methods which are usually adopted in this country.

In an introductory chapter a brief survey of the development of illustration processes is given, which will be of some interest to those who are unfamiliar with this subject.

The chapter on photographic equipment cannot be described, at any rate from an English point of view, as being quite up to date; the drawing that is given of a camera is of an obsolete type, and the drawing of the dark slide shows the old arrangement for supporting the ruled screen in it. Of course, this is not met with in modern studios, and yet no reference is made in the book to the use of screen gears fitted into the body of the camera.

The section referring to half-tone screens is satisfactory so far as the reference to ruled screens is concerned, but with regard to the use of the Metzograph screen it is entirely misleading; it is quite impossible to obtain satisfactory results with this useful irregular grain screen by following methods in acordance with the instructions which are given.

The description of the lens to be used for process operating is not very helpful; it is said the lens should be "reasonably speedy, and it is the safest plan to use a lens which is somewhat larger in size than the camera on which it is to be used." We suggest that a definite reference to the equivalent focal length of the lens for a particular size plate, together with the ratio of the diameter of the largest stop to the local length would have been more helpful.

The author states that the "theory of wet-plate photography, roughly speaking, is that the glass plate is coated with a sensitive collodion," which makes it evident that he is not familiar with the most elementary theory of the process. The strength of the fixing bath given is three ounces of potassium cyanide to twenty ounces of water. Our own experience is that this concentration of potassium cyanide will have a strong solvent effect upon the silver image.

The portions of the book devoted to stripping the negative and to printing and etching the plate are more satisfactory than those devoted to negative making; but in the formulæ we note some statements which would probably lead to disaster in practice. For example, the addition of forty grains of chromic acid to an enamel for working on copper of which the total bulk is eighteen ounces would almost certainly tend to "scummy" prints, although such a formula might work successfully on zinc.

The chapter on mounting and finishing the process blocks is well done, and may be read with interest and practical advantage. The whole of the machinery is described in a satisfactory way,

which will be helpful to engravers and printers alike, especially the section describing the hand finishing and engraving of the etched block.

The reference to high light half tone work confines itself to deep etched blocks; but there is no reference to high-light photo-lithography.

Some sections of this volume are of distinct practical value, and it is to be regretted that the author did not have as a collaborator someone who possessed a more accurate knowledge of the principles upon which photo engraving depends.

Der Aufbau des Photographischen Bildes. By Dr. E. Goldberg 85 pp. Halle: Wilhelm Knapp. Mk. 45.

In this country students of the scientific basis of photography know Dr. Goldberg very well as the inventor of the graduated sensitometric wedge which bears his name and has proved of such great use in sensitometric measurements since its introduction about the year 1911. Moreover, those who visited the Dresden Exhibition of 1909 will remember his score or so of cabinets, each providing a demonstration of one or another of the physical phenomena connected with photography. The visitor was given simple instructions on the outside of each box for the performance of the experiment himself; and the design and construction of the cabinets showed remarkable ingenuity in bringing the facts upon which the processes of photography depend before those unacquainted with them in a most interesting way.

Dr. Goldberg, who since the year 1917 has been director of the research laboratory of the Ica camera works, has for some years past occupied himself with experiments made for the purpose of providing, so to speak, a quantitative basis for the operations concerned in the taking and printing of a photograph. Accepting, as one is bound to do, the dictum of the late Lord Kelvin, namely, that we do not properly understand a process until we are able to express its working by numbers, it is clear that the making of a photograph is a process which is still very far from the state of being capable of numerical calculation from start to finish. Hitherto, endeavours to render it quantitative have centred chiefly round the problem of exposure, directed to this end by the investigations of Hurter and Driffield, Watkins, and many others. Yet there still remain many factors for which provision is not made in even calculating exposure, to say nothing of the development and printing of the negative. A good example of this qualitative condition is the system (if it can be so called) on which allowance is made for the character of the subject in calculating exposure with a meter or by any other means. It is usual to adopt a "standard subject" and to employ a factor according as the subject differs from the standard. Thus, we are told to use a factor of ½ if the subject is "open landscape"; 1-10th if it is "sea and sky"; or 4 if it is "extra dark foreground."

Now the purpose of Dr. Goldberg's book is to outline a system according to which these more or less indefinite descriptions are replaced by figures based on measurement of the phenomena to which they refer. And in point of fact the first chapter appropriately deals with the character of the subject and of the respects in which it is modified by atmospheric conditions. Following Renwick, Loyd Jones, and others, he considers the range of light-intensities in the subject, as seen by the eye and as measured by a photometer, and adopts as the numerical description of a subject the ratio of the highest to the lowest light-intensity, or rather (for convenience in dealing with the subsequent part of the process, namely, the making of the negative and the print) the logarithm of this ratio. The next main portion deals with the reproduction on the ground glass of such a range of light-intensities by lenses of various kinds and under different photographic conditions. Then we come to the recording of this image, in negative form, on the plate, the fundamental quantitative principles of which were laid by Hurter and Driffield, and finally to the making of prints from the negative.

It is scarcely necessary to say that the text book is not a manual of practical photography, and we suppose the mere mention of the word "logarithm" is enough to frighten away even those whose acquaintance with German may incline them to a study of the book. But the merit of Dr. Goldberg's work lies in the comparative simplicity to which he has reduced the theory of tone reproduction in photography. True, he neglects certain factors, for example, the colour of the image on a negative; it is assumed in his pages that the negative is invariably a neutral grey, and in like manner he does not take account of the effect of intensifiers or reducers in modifying the scale of gradation. Nevertheless, a very great deal of photography, since it is done with non-staining developers, may be said to conform to the conditions which he assumes; and thus his symbols do not acquire the forbidding complexity of those put forward by Loyd Jones and others who have elaborated a set of symbols for the theory of tone reproduction. To describe the merits of the book in the fewest words, it tempers the wind of H. and D. to the shorn lamb of the photographic reader. The many illustrations and diagrams, some of them most ingenious, and inserted in the book as actual photographic prints, serve to help the comprehension of the text, which actually requires scarcely any mathematics for its understanding. No other work on the theory of the photographic process has brought the subject within such short compass, has subjected it to such precise and clear treatment, and has taken such pains to show, throughout, the relation of the theory to the operations which a photographer performs in taking his negatives and making his prints.

New Materials.

Narrow Art Mouldings.—Mr. T. W. Forrest, 27, Bower Road, Hackney Wick, London, E.9, sends us some specimens of the very artistic narrow mouldings, which he is manufacturing in gilt, copper, antique, oxidised, pewter and silver surfaces. The mouldings are supplied in the two widths of three-eighths inch and half-inch, and may be had in bead, bevel and flat sections. We have nothing but praise for the extremely artistic appearance of these mouldings, which, hitherto, Mr. Forrest has supplied only in the form of made-up frames. Recent extension of his factory has enabled him to cater for the larger demand represented by the purchase of the mouldings in 100-ft. lengths. The prices range from 24s. to 28s. per 100 feet, and Mr. Forrest offers to send a sample 100 feet of assorted sections and colours, carriage paid to any address for £1. Photographers wishing to make the acquaintance of mouldings, which are admirably adapted for the display of any descriptions of photographs of moderate size, will be well advised to see these attractive styles for themselves by ordering a sample set. It should be added that Mr. Forrest is a manufacturer also of polished wood mouldings, including inlaid,

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Monday, July 31.

Southampton C.C. Competition.

Tuesday, August 1.

Rochdale A.P.S. Outing to Reddisher Woods (Bury).
South Glasgow C.C. Outing to Bothwell Castle.

CROYDON CAMERA CLUB.

Mount Terror, after quiescence for over six years, burst into eruption last week, the secretary, Mr. J. M. Sellors, projecting a flow of practical instruction on the art of "Lettering," at which he is an adept. It is a most useful one for many, including secretaries of photographic societies, not only for announcements on

the notice board, but for graph-copied circulars dealing with special matters not included in the regular printed syllabus.

One of the surest ways of putting Mr. Sellors in benign mood for a reasonable period is to allude incidentally to his really remarkable skill in lettering. So every hope was entertained that the evening would pass without any obligation on his part to refer to his audience as "miserable blighters," or "hopeless addlepates," as is his pleasing wont.

In measure the members were spared a critical review of their moral and mental attributes by the diversion of vials of wrath on to an unconscious brass band below, which played with great resonance and hostility between the instruments. It was followed by a cornet solo, with a rendering of the "Lost Chord," which made all wish that every individual note was also missing. Mr. Wadham declined to go outside and suck a lemon, and the nuisance continued.

When lettering, Mr. Sellors said, avoid copying from formal type, and particularly from imitating the style adopted by the professional sign writer. There are many cheap and rather nasty books obtainable, giving various alphabets. Far and away the best text-book is "Lettering," published by Bacon & Co. (the map publishers), of Fleet Street, which contains much instruction, and a large assortment of alphabets. Price now is in the region of five shillings.

Any good paper with smooth, but not glazed surface, is suitable. Inks are various; liquid drawing-inks in many colours can be purchased from artist and engineers' supply shops. The corks are usually fitted with a dipper for filling the pens, which are better not inserted in the bottle. Ordinary writing-inks can be used, but they, like present-day whisky, contain too much water. If this is evaporated they are fairly satisfactory. A good ink is Waterman's "jet-black," as supplied for fountain pens; a cheap substitute, Stephen's "ebony stain," which reproduces well for process work on some papers, however, the latter dries with a gloss.

He then turned to implements, and produced about fifty weird pens of varied size, and a dozen or so distinct breeds. For each colour he reserves one pen, identifying it by staining the end of the handle. It was gently and very politely pointed out to him that talent inferior to his own genius would hardly require such a galaxy of pens, and if he would be kind enough to mention a few which would cover most purposes it would add to the value of the lecture.

Luckily, no offence was taken at this request, and he said that for diagrams Mitchell's "Witch Parcel Pens," supplied by Strakers, at 3d. each, are useful. For medium and large lettering, Boxall's "Automatic Pens," supplied by Reeves & Sons, artists' colourmen, are excellent. They are supplied in three grades—solid, double-line, and shading, at 1s. 3d. to 1s. 6d. each. J. Gillott's pens for ornamental writing are also very serviceable for all round work. They can be obtained from most stationers, eleven assorted on a card for 7d., or in boxes of two dozen of one width.

Among others were "Scribe" (reed) pens, capable of being trimmed like a quill, and sold by Pitman & Sons, Parker Street, Holborn, and the "Beaver" pen, a class by itself, for fine unbroken lines, sold by Stamford (map publishers), of Long Acre.

The various styles of lettering were well illustrated by specimens executed by Mr. Sellors, which were passed round. They were mostly in the nature of homilies addressed to the members of the club, and hardly of complimentary nature. The demonstration concluded with a generous distribution of free samples. Of late, he said, he had been bitterly disappointed at the absence of this feature in so many demonstrations. A most hearty vote of thanks was accorded the lecturer, who throughout the evening had been fully exposed to the poison gas proceeding from the president's Commercial Road Havana.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, W.C.1, on Friday, July 14, 1922, when there were present: Messrs. Marcus Adams, Angus Basil, Arthur Bennett, Frank Brown, W. B. Chaplin, H. A. L. Chapman, Gordon Chase, Alexander Corbett, C. F. Dickinson, W. E. Gray, Reginald Haines, George Hana, William Illingworth, Herbert Lambert, R. N. Speaight, H. A. St. George, F. G. Wakefield, Halksworth Wheeler, with Mr. Alfred Ellis (secretary) and Mr. Griffiths (Editor of Record); Mr. Alexander Corbett, in the chair.

The Secretary read a letter he had written to a correspondent who had complained that the Council had not adopted a fighting policy in certain particulars. It was agreed that the secretary's letter should be incorporated in the minutes.

Replying to the charge that the Council was not sufficiently alive to the interests of its members, the Secretary said: "With reference to your remarks re the charges for electric current at power rates, I fear you do not realise the magnitude of the undertaking when you suggest that the P.P.A. 'should fight it out in the common interest.'

"The Council have the best possible advice on this subject, and are fully aware of the powers that have been conferred by Acts of Parliament on electric light undertakings. The question is so vital to all electric corporations that nothing less than a House of Lords' decision would satisfy them, and would probably cost some thousands of pounds."

The Secretary reported that the number of members stood at 1,013. The number who had signed the forms up to the present was 724. The number who had paid last year's subscription was 856, and the number who had paid this year's subscription (due July 1) was 273.

The Secretary announced, with regard to the dispute with two papers on taking single portraits out of groups, that the Council of the Press Photographers' Association was taking counsel's opinion.

It was agreed, on the Chairman's suggestion, that the question of charging for prints sent out for Press reproduction purposes should be discussed at a later meeting.

In the matter of a dispute concerning the name of a photographer appearing under certain book illustrations, the firm which had acquired the business of the photographer in question claiming that the name should be that of the firm and not that of the individual, it was agreed that the secretary and Mr. Adams should go into the matter.

Offers of terms by two insurance companies were considered, and the matter was referred to the Finance Committee for decision.

The receipt for the incorporation law costs (£105) was produced, and it was agreed to send the solicitor a letter of thanks from the Council for the manner in which he had conducted the business.

The Congress.

Mr. Wakefield reported that quite a considerable number of stands had been taken since the last meeting of the Council. He agreed to a suggestion that certain firms who had not yet agreed to take space should again be written to at his discretion, and reminded that the closing date was July 20.

Mr. Wakefield submitted proposals for the printing of tickets and for evening arrangements. It was agreed, on the proposition of Mr. Haines, seconded by Mr. Lambert, that the Thursday evening in Congress week should be set aside as the assistants' evening, and a suggestion by Mr. Wakefield was adopted that it should be intimated on the tickets issued for other than members of the Congress, and that the pictures in the Congress room would not be on view any evening after 6 p.m., and that over the entrance to the Congress room the words should be placed "Members Only." Mr. Wakefield was authorised to proceed with the tickets, the exact form being left to his discretion and that of Mr. Corbett as the Exhibition Committee. The number of tickets which might be required was stated to be about 3,000.

The Secretary reported that he had seen the manager of Prince's Galleries with regard to the provision of light refreshments on the assistants' evening. Some discussion took place on the best arrangement, and in the result Mr. Gordon Chase was asked to call his committee together and to decide upon the necessary arrangements for the issue of assistants' tickets, their endorsement by the principals, and the way in which the refreshments should be provided. The motion that the committee have full power to deal with the matter was proposed by Mr. Adams and seconded by Mr. Speaight, and agreed to.

The Secretary reported that he had an offer by a capable journalist who was in touch with the editors of newspapers to circularise items about the Congress during the preceding eight weeks.

Mr. Illingworth moved, and Mr. Adams seconded, that the offer be accepted, and this was agreed to.

A letter was read from a member suggesting a visit to the National Portrait Gallery. The letter was handed over to Mr. Haines, chairman of the Programme Committee.

The Secretary reported that the Kodak Company had sent out forms to the leading Continental photographers for attaching to the prints sent to the exhibition. This action was appreciated.

Mr Haines gave an account of the proposed programme of the Congress. On the Monday morning there would be an informal gathering of members to register; in the afternoon the formal opening, and in the evening the reception of President and Council. On Tuesday morning a visit to some place of interest yet to be finally arranged. On Tuesday afternoon the President's address, and in the evening a lecture. There would be the same programme on Wednesday, with demonstrations and lecture in the afternoon. On Thursday it was proposed to have a special outing, and the evening was the assistants' evening. On Friday it was hoped in the morning to visit some studios, and in the early afternoon the Salon; later to hold the annual general meeting, and at night to have the dinner. On Saturday it was proposed, if possible, to pay a visit to the Royal Photographic Society's exhibition.

Mr. Speaight thought that the President ought to give his address at the beginning of the Congress.

On the proposition of Mr. Frank Brown, it was agreed that Mr. Haines should be empowered to arrange for music.

The cost of programmes was also considered. It was agreed, on the motion of Mr. Illingworth, that 6d. be charged for programmes, including the exhibition catalogue.

Mr. Speaight gave notice that at the earliest possible moment he would call attention to the expenses of the exhibition at a meeting, to be called, of all the various exhibition committees.

Nominations for Annual General Meeting.

Mr. Speaight nominated as President for next year Mr. Alexander Corbett. Mr. Illingworth proposed, Mr. Adams supported, and the resolution was agreed to unanimously and with acclamation.

Mr. Lambert proposed the nomination of Mr. Speaight as treasurer. This was seconded by Mr. Frank Brown, and also agreed to unanimously and with acclamation.

Both Mr. Corbett and Mr. Speaight acknowledged the compliment.

Lots were drawn to decide which members of the Council should retire at the annual general meeting. The names of the members of the Council were placed in a receptacle, and were drawn by the Chairman as under :—

Town.	Country.
Mr. Basil.	Mr. Chaplin.
Mr. Haines.	Mr. Read.
Mr. Hana.	Mr. Spink.
Mr. Lang Sims.	Mr. Wedlake.

The Secretary said that he hoped to submit the draft report of Council to the next meeting.

Railway Rates.

Mr. Gray described some correspondence he had had with the Great Western Railway Company relating to luggage carried by photographers, following upon an occasion on which he was charged excess luggage for his photographic equipment. He had been informed that every month the different railway companies had a joint meeting to decide matters which affected them all, and that at one of these meetings, by a very small majority, it was decided that photographers should pay for their luggage. But the contrary view was so strong that the matter was raised again the following month, with the result which appeared in a letter he had received, dated July 5, from the superintendent of the line at Paddington, who wrote:—"Adverting to our previous communications and my representative's interview with you, the railway companies now agree to photographic apparatus accompanying passengers travelling for the purpose of taking views for a firm of photographers being conveyed free up to the weights allowed to ordinary passengers, and I have pleasure in enclosing a postal order for 7s., receipt for which kindly acknowledge on the attached card.—Yours faithfully (sd.) R. H. Nicholls."

Mr. Gray said that the effect of this was that they could now carry luggage up to 100 lbs.

The Chairman said that this was a very valuable concession, and that the Association was very much indebted to Mr. Gray.

The Chairman said that he was more than surprised and pleased at the first issue of the Record, and he moved a vote of thanks to Mr. Hana, Mr. Adams, and Mr. Griffith, the editor, and all who had served on the committee.

Mr. Lambert seconded, and said that the committee was to be congratulated on the way in which it had got over the difficulties.

The vote of thanks was accorded unanimously, and Mr. Hana and Mr. Adams briefly acknowledged the compliment, and asked for further suggestions for succeeding numbers.

The Secretary read a large number of letters from members asking for advice or information in certain circumstances; also his replies. The various matters dealt with included negatives broken in post, copyright infringement, advertisements, Sunday trading, rate of wages for assistants, the liquidation of a photographic dealer, a refusal to pay the new scale of Press fees, views taken for a local paper, the assessment of a studio, the photographing of a public school, a complaint against a newspaper for taking estate photographs at a low rate (a matter on which the secretary was instructed to write to the journal concerned), commercial prices, copyright reproduction, the purchase of a business, and various other matters.

The secretary's replies were in all cases approved, and at the close Mr. Adams and the Chairman complimented the secretary upon the precise and painstaking way in which he had dealt with all these inquiries, which formed a good indication of the "appeal work" of the Association. It was also suggested that a synopsis of the cases should appear in the Record.

The names of Miss Barrett, Mr. A. Higginbotham, Mr. Hanson, Mr. R. Harding, Mr. C. F. Usher, and Mrs. E. Cross were submitted as members, having been duly recommended, and their adoption was proposed by Mr. Illingworth, seconded by Mr. Adams, and agreed to.

Certain deaths of members were reported, including that of Mr. Miles, of Miles & Kaye, and the secretary was asked to convey the regret of the Council.

A few resignations were submitted, and in some cases the reasons were given. In one or two instances the secretary had succeeded in getting the member concerned to reconsider the matter.

Mr. Hana reported that the results of the questionnaire dealing with prices of commercial work would be tabulated immediately, and he asked for permission that they might be published in the Record, but without names. This was granted.

This concluded the business of the Council, which had occupied more than four hours.

News and Notes.

Burglars Defeat the Camera.—In a burglary at Matlock last week a police photographer found that the burglars had wiped whitening over the places where finger-prints should have been visible, in order to prevent photographs being taken.

A Job for Lady Photographers?—Most of last Sunday's newspapers published the following paragraph:—"Mrs. Helen Sibthorp, of Hornchurch, Essex, aged 100, has never had her photograph taken, and has a strong objection to camera men coming near her."

Beach Photographers' Losses.—The inclement weather experienced at most seaside resorts during the past seven or eight weeks has played havoc with many beach businesses. According to one daily paper many of the beach operators are taking £50 per week less than they took during the phenomenal weather last year, when only one small shower was experienced between May and September.

Photographic Exhibition at Geneva.—The "Board of Trade Journal" states that a photographic exhibition will be held at Geneva, in May, 1923, one section of which will be devoted to an international display of all photographic apparatus and allied products. A limited number of copies of the general regulations is available on application to the Department of Overseas Trade, 35, Old Queen Street, London, S.W.1.

Photographs for Reproduction.—The attention of the Professional Photographers' Association has been called to the action of newspaper editors in asking for a supply of portraits of celebrities for filing purposes. Members are advised not to supply them, unless the editor agrees to pay 1s. for each photograph at

the time of delivery, and that this amount is to be over and above the fee payable when the photograph is reproduced.

A Kodak Condensed Price List.—A list of the prices only (without illustrations or descriptive particulars) of the many requisites made and supplied by them has just been issued by the Kodak Co., and is obtainable free on application to Kodak House, Kingsway, London, W.C.2. In this condensed form the list runs to 72 pages. It is provided with an excellent index, and contains a reference, opposite every article, to the firm's 1921 descriptive catalogue, in which full particulars of the goods may be found.

P. P. A. Congress.—For the purpose of assisting members and friends attending the Congress, the secretary of the P.P.A. has arranged with Messrs. Cook & Son, to reserve any hotel accommodation which may be required. Members wishing to avail themselves of these facilities should send a deposit of one pound to Messrs. Thos. Cook & Son, Ludgate Circus, London, E.C.4, when the desired rooms will be reserved. A receipt will be issued for the amount in question, and this will be accepted in part payment of the hotel bill. Intending members of the Congress are reminded of the importance of making their hotel arrangements at the earliest possible moment.

T.E.B. Mounts and Albums.—Messrs. W. Butcher and Sons, Ltd., Camera House, Farringdon Avenue, London, E.C.4, have just issued a profusely illustrated catalogue of 84 pages describing the many styles of mounts and albums manufactured by them. Folder mounts in considerable variety figure in these pages and include some most attractive new styles. Single mounts and many types of slip-in mount for the amateur are also listed and illustrated, in addition to a great variety of albums and other accessories, such as transparent envelopes, passe-partout materials, and wallets for D. and P. The list is published for the use of dealers and professional photographers, and is sent on receipt of trade card.

Windmill Pictures for Londoners. — Windmills have always been favourite subjects among view-taking photographers (writes a correspondent), and habitués of exhibitions will recall many notable pictorial masterpieces of mills by J. M. Whitehead, Hawksworth Wheeler and others. One does not associate London with windmills, although one once stood in the Strand and two upon Blackheath—the latter being remembered by some persons still living. The "Evening News" of the 18th inst., however, contained a special article, with photographs, on "London's Circle of Windmills," drawing attention to the pictorial possibilities and present state of windmills within easy 'bus rides of London. The eight examples illustrated were those at Arkley, Wimbledon, Upminster, Shirley, Coulsdon, Coleshill, Keston and Horndon.

Camera Outings in Australia.—The Australian amateurs are, it appears, more keen on winter-time outings than are the members of photographic societies of our own country. The current issue of an Australian photographic journal (writes a correspondent) gives an account of an outing of the Photographic Society of New South Wales, on May 6 last, when there was a good attendance and over 70 exposures made. The same publication also gives an account of an outing by the members of the Adelaide Camera Club, on April 15, and these are by no means isolated events. April and May are not the best of Australia's photographic months, but the amateurs are too keen to give up outings during their dull season. The average number of hours of sunshine at Adelaide during April is 176, but in Sydney during May the number is only 111, and the numbers of "clear days" are 3·8 and 2·9 respectively.

Legal Photographs.—In the "Motor" of July 18 last is an article which well illustrates the value of photography as an accessory to legal proceedings. It concerns a motor accident which occurred last October at Rochampton, and in which four cars were involved. One of them was being driven by Mr. G. W. Lymbery, of the Photopress Agency, 3, Johnson's Court, Fleet Street, and the plaintiff in the action. At a cross roads a Talbot car collided with a Dodge car at the moment when Mr. Lymbery was passing in his Swift, with the result that the Talbot crashed into his car, the road was blocked in an instant and thus further damage to the Swift was done by a Ford which was travelling just behind it and was unable to pull up in time. Although violently shaken by the collision, Mr. Lymbery, who had a Press camera with him, was able after a time to take a series of five photographs of the accident before the cars were moved. These proved of great value in court, and no doubt were largely instrumental in obtaining judgment in Mr. Lymbery's favour for £120, with costs, against the owner of the Talbot.

FILM EATING INSECTS.

To the Editors.

Gentlemen,—Most photographers, I believe, are very well aware of the damage the common or garden earwigs and the kitchen cockroach can do to a drying negative, but at the present time there appears to be in many of the London suburbs—and maybe in the provinces as well—a plague of a peculiar kind of beetle known in polite circles as a "Silver Fish," though many venture to give it names not to be found in any book on natural history. These little fellows, who inhabit sinks and damp rooms, will play havoc with damp negatives, for they have a well developed taste for photographic emulsion on plates, films and papers, commencing their meals at the outer edges and working inwards to the centre. The damage done to several negatives drying in a rack was put down to earwigs, until I discovered the real offenders at work. Not being fond of daylight the silvery visitors are not easy to entrap, and maybe some of your readers, now that the plague is about, have met with damaged negatives and prints, and have been unable to trace the cause.

The culprits are about half-an-inch long, rather like a miniature whiting on short legs, smooth to the touch, being covered with a sort of white silvery coat. Possibly some of your readers have found an infallible remedy for them; all I can do is to beware of them and destroy them when seen.

I have heard of these insects attacking dry and even old negatives, and of them finding their way into boxes in which negatives are stored, and there attacking the gelatine. My own experience, however, is limited—for the time being, at any rate—to damp or half-dried negatives.—Yours faithfully, Near East.

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—I would like to welcome Mr. Bierman's article in the "British Journal of Photography," of July 14, on "System in Half-tone Operating," because I am only too keenly aware how much has yet to be done before we are in possession of complete knowledge of the half-tone method such as will enable factory operations to be carried on with that precision which is done in so many other branches of technical work.

He states that there is a difference in the result when working with coarse or fine screens, and then attempts to show the reason for this difference. This variation with the fineness of the ruling I do not now propose to discuss. I am interested to learn that Mr. Bierman has, in the course of long experience, found this difference to exist; in fact, I suppose most people who have worked with a variety of screen rulings have noticed differences, but exactly what the difference is requires further careful work carried out in such a manner that quantitative results can be established.

I must, however, express some doubt as to Mr. Bierman's explanation of the cause of the difference being the diffraction pattern produced when the image of the stop is photographed. The resolution in the image which is formed by any lens is dependent upon the size and form of the aperture. This fact is often lost sight of in photographic work, but becomes of great importance in astronomy, for the shape of the images of stars is dependent, for the most part, upon the aperture of the telescope objective, the diffraction pattern being larger than the true image of the star would be, and when the aperture is divided into a number of small, regular apertures, the diffraction pattern becomes very pronounced. Now I suggest that Mr. Bierman's haloes are diffraction images or patterns formed on the retina of the eye, or the photographic plate of the camera used for photographing the effect, by the apertures of the half tone screen that happen to be sending light into the lens in question. The complete pattern formed is a somewhat complicated one. It consists of four series of overlapping images of increasing order formed at right-angles to each other, and so giving the effect of a cross of light. In between

the arms of this cross are secondary images which are not often seen, and as the intensity of all these images diminishes from the central image outwards, so when they are photographed, especially with a "hard" working plate and developer, there is a tendency to lose the faint ones, and thus the lens aperture when photographed in this way might appear to be enlarged; but it must be remembered that this image is formed at the focus of the camera lens, and that there is no enlargement of the aperture of the process camera, either real or virtual. The question I should therefore like to ask is, how does this diffraction image affect what happens in the plane where the half-tone dot is formed?

There is, of course, another diffraction pattern formed whenever the aperture of the process camera lens is small, but this is formed close behind the screen ruling, and its effect, if any, would be merely to break up the half-tone dot.—Yours faithfully,

A. J. BULL.

MONOCHROME OR COLOUR IN PICTORIAL PHOTOGRAPHY.

To the Editors.

Gentlemen,—I feel sure that I express the feeling of the great majority of those who make or take photographs, including some of the recognised top-notch experts, that they would, if they could, prefer to make their pictures as they appear in nature with their real colours. There are some also, among the experts, who say that they prefer pictures in black and white. I suppose the question of individual taste and temperament enters largely into the preference, although I feel sure that the difficulties, the patience and skill required in mastering colour methods, are responsible for preventing as many from producing pleasing results as would be the case if the methods of working could be made simpler. In some cases the suitability of environment in displaying a picture to the best advantage applies as much to a photograph as to a painting, and there are occasions and places in which a good black-and-white photograph is undoubtedly preferable to any picture in colours, just as is the case with a good engraving or etching in black and white. My contention is that, on looking at the general effect of even the best exhibition of photographs, or selecting them individually, one cannot help feeling that so much of the charm and reality of the subject is missing through the absence of the real colours of the picture. I think there can be no doubt that if, when the science of photography was first introduced, it had been possible to make pictures in their natural colours as seen on the focussing screen, as easily as in black and white, there would have been few black-and-white photographs. If the subjects chosen for photography were limited to wet, dull days, winter scenes, night scenes, mists and fogs, and portraits of Kaffirs and Hindoos, in which there is little colour, well and good, but to suggest that the glorious shades of green of the foliage of trees or the healthy complexion of a charming Anglo-Saxon girl, for instance, are as pleasing when represented in black and white as in the colours which nature provides—well, all I can say is that I am sorry for those who are content to see things thus, and I am thankful for the gift of the power to see things not only beautiful in composition, form, tone, balance, perspective, and all the qualities of which a good black-and-white picture consists, but, in addition to these, perhaps the most valuable quality of colour, without which most pictures are lifeless.

There are still many people who do not know that it is possible to make photographs on paper in natural colours, and have never seen any, and there are also many, no doubt, who have struggled with all sorts of problems and difficulties in the hope of producing more direct colour photography, and have arrived at a certain degree of excellence, which is in most cases not quite good enough. What is needed is continual perseverance, an intelligent appreciation of the requirements, absolute exactness of manipulation, and good judgment. Amongst those who have been wonderfully successful in this work, and who have exhibited some beautiful pictures in many of the exhibitions in different towns, Mr. S. Manners stands out pre-eminently. He has been so successful with his methods of producing photographs in natural colours on paper that there is much demand for information of his methods, and he is kept very busy supplying the necessary information and materials with which he produces these beautiful pictures at the Raydex Photo Co. Works, 71, Lavender Hill, London. I believe he intends to submit some very fine examples of this photography for the forthcoming exhibition at the Royal Photographic Society in September, when those who do not know the possibilities of colour photography will have an opportunity to see them, and I feel sure that with the improvements which Mr. Manners has worked out in the different stages, and materials used in the process, many who see the results will not be satisfied until they can improve on their black-and-white photographs by making many of the subjects in natural colours.

Mr. Manners deserves full credit for his patient, painstaking efforts as a pioneer in producing all the requisite materials and giving the necessary instruction to carry the work out, and to those who know something of the difficulties with which he has had to contend, and the handicap of appliances and conditions under which he has done this work, the results are simply wonderful; but that is frequently the way in which some of the best things are produced.

I have written this, not with any intention of advertising Mr. Manners's Raydex process—much as he deserves it, and worthy as it is of all the advertising possible—but to try and get the opinion of good authorities in photography on the subject in the condensed form of a letter which will be instructive.—Faithfully yours,

LOUIS H. JOHNSON.

38, Heathhurst Road, Hampstead.
July 24.

THE PRESERVATION OF NEGATIVES.

To the Editors.

Gentlemen,—A few days ago I went through some boxes of negatives that had lain untouched for about twenty years, when I made a few discoveries which may interest your readers, and from which a few lessons may perhaps be learned.

It is a matter of opinion as to what is the very best method of storing negatives, some preferring one system and some another. Many years ago I was employed in the workshops of one of the largest firms of view publishers on the Continent, where I for a time had charge of their immense stock of negatives—negatives dating from the wet-plate days, with, of course, dry-plate negatives from the date of their coming in. All the negatives were varnished and stored in grooved boxes, and all were in a perfect state of preservation. Stored in this way, they took up an enormous amount of room, and were stocked in quite large warehouses. It was certainly an excellent system, but few of us can spare the room to store negatives in this way.

I was never able to get the formula for the varnish used, and I have never met with anything quite like it since. It was as white and as liquid as water, had the smell of benzine, was rather sticky, but dried very quickly and very hard.

In my own business it has been my habit to store negatives in the original plate boxes, and this is the plan adopted, I believe, by the average worker to-day, sometimes with plain white paper between the plates and sometimes without. I gave up varnishing every negative many years ago, and to-day I varnish only those I consider valuable. In cases of very valuable negatives, however, I invariably make transparencies from them, in case of accidents. But to return to an analysis of my old stock.

The varnished negatives had kept splendidly, but around the edges of the unvarnished ones were nasty discolorations. The most curious fact, and one I wish to emphasise, is that all negatives that happened to have been laid film side upwards and at the top, *i.e.*, exposed to the air, were very spotty and badly faded. They were, of course, covered by the lids of the boxes, but not being airtight, air gained access to them. The negatives were stored on the top of shelves in a room in which the air has not been of the purest, gas has been burned in large quantities, while the tobacco smoke that has ascended to those boxes has been too terrible for words. The negatives stored at the tops of the boxes, but film side downwards, did not show the spots and fading that the film-upwards negatives showed. Therefore a lesson to be learned in cases where negatives are stored in plate boxes is to place the top one film side downwards.

A few of the negatives were in paper bags, and the appearance of these after their twenty years' rest teaches a lesson. A negative stored with its film side facing the front of the bag is in a good state of preservation, but those negatives that happened to be housed with the glass side touching the front of the bag, and the film side on the side of the pasted seam and loose flap of the bag, are badly marked, especially those which have been intensified.

As an interesting experiment, give someone a negative and an empty negative bag, and ask that the negative be placed carefully

inside the bag. Ninety-nine times out of every hundred the worker will place the film side touching the seam and flap—which is the wrong way if negatives are to be kept bagged for years. One invariably holds an empty envelope flap side upwards, also a negative film side upwards, and when placing the latter inside the former, one never—or very rarely—thinks of reversing one or the other so as to bring the seam and flap in contact with the plain glass. It appears a small and insignificant point, but it is really an important one.

I notice that one of the Continental technical journals advises placing between each pair of negatives (and touching the films) a piece of white paper which has previously been soaked in a 5 per cent. solution of potassium bichromate, dried, and exposed to daylight. The action of the prepared paper is not explained, but it is stated that it is an advantage for preserving in contact negatives that have been developed by different methods. It would be interesting to know more about this method of storage.—Yours faithfully,

ELLIS D. SHORTT.

SOFT-FOCUS LENSES.

To the Editors.

Gentlemen,—In the "Paris Notes" of your current issue, I note with interest M. Clerc's remarks with reference to uncorrected lenses, and as this question has not yet received the amount of attention that it deserves in this country, perhaps I may be permitted to extend it a little.

I do not think that it is generally realised by my professional brethren the great advantages that may be obtained by the use of the simplest optical equipment on their studio cameras. As an instance, I may mention that for years my favourite lens has been a simple plano-convex lens, which I obtained from Messrs. Sharland at the cost of 2s. 6d! It would have been considerably cheaper than this, but I paid double for the privilege of selecting one free from coma.

This lens for a considerable time resided at the inferior end of a tin which originally provided a home for fifty cigarettes, but recently I have had it provided with a mount more in accordance with its increasing importance. It is of 22 in. focus, and 2½ in. in diameter, giving an aperture of something like *f*/8.5. This, I find, is quite ideal for head and shoulders on a 12 x 10, the result being approximately sharp, yet having a delightfully soft character impossible to get by other means.

Unfortunately the whole movement in the direction of these "naturalistic" lenses is under a cloud owing to the vile excesses of certain misguided American workers, who, by pushing things to extremes have covered it with ridicule, so much so that in many cases it is a matter of conjecture as to what the subject may be. Obviously, by increasing the aperture of these simple lenses one can make the rendering of the subject so fuzzy that it merely disappears in fog. Personally, I think that any aperture larger than *f*/7 is inadvisable. The true use of lenses of this type should be merely to destroy small irritating details and so to eliminate retouching and until this view is generally accepted a real movement for good must remain in abeyance.

In my own experience I never found any difficulty in focussing. On examining the image on the focussing screen through a magnifier, it will be noticed that as the screen is racked to and fro, the image of a sharp, high-light (that on the eye is generally the best) will pass through the usual spectral range from red to blue, and the correct position for the screen is that when the blue image tends to become fuzzy nearing the lens. This is, of course, when working with the usual blue-sensitive plate. When working with panchromatic plates and a filter, then the focus is adjusted in a similar manner to the colour of the filter in use, but it should be pointed out that in such a case the image is much more fuzzy, as all of the aberrant colours are recorded.

Quartz lenses also have a great charm peculiarly their own. They give a peculiar ethereal quality which cannot be obtained with a glass lens, but they have faults which are not shared by glass. As the main effect is gained by passing the ultra-violet rays the colour rendering is bad, and the curvature of the field is much more severe. On the other hand, as the chromatic aberrations are not so excessive, they may be focussed more easily—the sharpest visual will do quite well. If a lens of this type is obtained, it should be a crossed bi-convex of the usual formula (with the two radii in the ratio of 1 : 6) and used with the flatter of the curves towards the sitter.

If I may presume to offer advice to would-be experimenters with this class of lenses, I would say, first make the focal length of the lens as long as possible, preferably double the diagonal of the plate in use, and, secondly, keep the aperture low, and not to exceed *f*/7, which in these days of ultra-fast plates is quite usable. Also keep away from full lengths.

Some two years or so ago, I spoke on these matters at the Royal Photographic Society, since when I have been inundated with letters from all parts of the world, so, perhaps, you will permit me to state that Messrs. Sharland, of Thavies Inn, Holborn, will supply lenses of any type in any possible size either in glass or quartz. I have always found them most courteous and obliging, and always ready to do their best for a customer.—Yours faithfully.

ARTHUR C. BANFIELD.

The Saint James Studio, 49, Old Bond Street, W.1.

July 24.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. C.—It is rather a tricky business to uncement a lens, which, apparently, is what your lens requires. It is far better to send it to an optician to be re-cemented. The Premier Optical Co., 63, Bolton Road, Stratford, London, E.15, is a good firm for doing jobs of this kind, and probably would charge you only a few shillings.

J. L.—Some of the rolled plate has a slight greenish tinge, which is not enough to affect the exposure, but we have not found that, even after many years' exposure, it turned yellow. You will be quite safe in selecting this glass, but naturally you will choose a sample which is as nearly colourless as possible. There is considerable difference between various makes in this respect.

G. M.—(1) Some glasses are liable to the surface tarnish which yours seems to be suffering from, a defect which is aggravated by storage under conditions of damp. We strongly advise you against doing anything to the lens except gently rubbing it over with a very soft piece of cambric moistened with pure spirits of wine. If this does not clear away the stain, you should send the lens to the maker.

W. H.—(1) We imagine from what you tell us that the lens is a Goerz double anastigmat, formerly sold as the "Dagor," of 7 inches focal length. (2) Messrs. Goerz used formerly a system of marking diaphragms different from the ordinary F. numbers. The F numbers equivalent to those which you quote are as follows:—4.8, *f*/6.8; 6, *f*/7.7; 12, *f*/11; 24, *f*/15.5; 48, *f*/22; 90, about *f*/30; 192, *f*/45; 384, *f*/62.

T. S. MANLEY.—We do not know about putting in clouds with an air brush, since many negatives would not allow of this being readily done, but any expert retoucher would easily work in clouds with a combination of pencil and knife work. Write to Mr. T. S. Bruce, 4 Villas-on Heath, Vale, Hampstead, London, N.W.3, asking for a price per negative, and, at the same time, send him a fair sample of your negatives.

E. B.—You can procure plaster busts in any size and in many styles from Messrs. D. Brucciana & Co., 254, Goswell Road, London, E.C.1. You will find "Gibson's Venus" a good model, as the head is naturally posed, not inclined up or down or twisted on the shoulders. The 100-watt lamp will answer for a spot light if you fit it in a suitable reflector, like a motor lamp, or use a condenser. If you want more of a flood of light behind the sitter's head we think 250 watts will not be too much.

M. F.—Cerium peroxide is an insoluble substance, and, therefore, is not a reducer of the silver image. The substance which is used as a reducer is cerium sulphate, which certainly can be made by dissolving cerium peroxide in sulphuric acid. We don't suppose that you want to go to the trouble of preparing the cerium

sulphate, and, in fact, would not recommend you to do so. Much better to buy the stock cerium sulphate solution, made by Lumière, from their agent, Mr. T. K. Grant, 89, Great Russell Street, W.C.1, from whom are obtainable instructions for the use of the reducer.

R. P.—Unfortunately you do not mention the size of camera. If, as we expect, it is half plate size, by far the better choice is a camera of the Anschutz type. This type is far more generally used by sports photographers than the reflex on account of its greater portability and handiness. Moreover, for photographing char-a-bancs, where very often you require to have the camera at the highest level convenient, the reflex is a rather awkward instrument on account of the higher position you have to take to look down the hood. Neither type of camera is suitable for regular studio portraiture.

H. C.—The following is the borax formula which was referred to. It is the one recommended by Wellington and Ward, both for negatives and prints:—

Metol	20 grains.	1 gramme.
Hydroquinone	20 ,,	1 ,,
Sodium sulphite (cryst)	200 ,,	10 grammes.
Borax (powdered)	200 ,,	10 ,,
Water (hot)	20 ounces.	500 c.c.s.

Dissolve in the order given, allowing each chemical to be in complete solution before adding the next. This developer keeps almost indefinitely in well-stoppered bottles.

L. Joy Boon.—(1) We can only assume that the bath was too much exhausted or imperfectly made up. Another cause would be staleness of the paper before printing. (2) The blue tint on sepia toned bromide prints is due to the presence of iron somewhere in the process, either in the water used for washing, or sometimes in the alum used for hardening the prints before toning. (3) Fixing for an hour will not do the prints any good, but if it does not reduce the depth of the image, it should not be doing them any harm. But it is quite useless to fix for such a long time. Much better to fix in two baths in succession, giving the prints ten minutes in each. (4 and 5) Impossible to say. (6) The markings on the oval print are evidently due to the actual eating of the gelatine by insects. This form of destruction is fairly common in this country, and we daresay much more so in India.

I. F.—We are afraid we cannot help you to find the photographs that you are seeking, for that we think you should inquire of one of the fishing journals; for example, the "Fishing Gazette," published by the Fishing Gazette, Ltd., 19, Adam Street, Strand, W.C.2., but we can tell you as regards copyright. The fee usually paid for reproduction of a photograph in a single issue of a journal is 10s. 6d. Therefore, if you can obtain the name and address of anyone who has the photographs you require, you should tell them that you would like to get a few prints and that you will pass on to the photographer the copyright fee for the reproduction of each which is paid to you by the publishers of your article. Some journals, of course, will not pay a copyright fee for each separate photograph, but will pay for the article and illustrations in a lump amount. Therefore, you must not commit yourself in promising copyright fees which you are not certain of obtaining.

A. H.—It would seem that the dark appearance in the photograph of the silver is due to the reflection of surrounding objects in the bright silver surface at the time the photograph was taken. To avoid this defect, which is particularly marked in the pedestal of the cup and in parts of the round plate, the best plan is to arrange the articles in a species of tent or tunnel consisting of a framework covered with thin muslin. The articles are arranged at the back of this "tent," and the camera placed with the lens pointing into the open front. In this way the only object which can be reflected by the articles is the white fabric of the "tent," and in this way a very much better rendering of the silver is obtained. The tent can be used in an ordinary studio, setting it up so that it gets a strong light, or it can be arranged with a few half-watt lamps just outside it. It need not be appreciably larger than is required for the arrangement of the articles to be photographed.

J. T.—It is a clear case of deliberate infringement of your copyright, and the people who have done it must, as you say, be completely ignorant of the subject of copyright, otherwise they would know that there is no escape for them. The only ground upon which an infringer can plead innocence in an action for infringement is that he did not know and had no reasonable ground for supposing that there was any copyright in the work which he had copied. It is extremely rarely that that plea can be put forward; and in the case of photographs every publisher knows, or ought to know, that copyright is created by the taking of the photograph and lasts for 50 years from the making of the negative. The Copyright Act authorises anyone in your position to take action for the delivery of all copies of the infringing publication, together with the plates, etc., from which the photographs have been printed. Action can also be taken in respect to damages, which in your case appear to have been substantial. We advise you to point out these facts to the publishers, and ask them what they propose doing in the matter. Do not name any sum which will satisfy you. Leave them to make an offer, and if they do not make a satisfactory one promptly the best thing you can do is to cause a solicitor's letter to be written to them pointing out that it will be necessary to take action against them in the County Court failing a satisfactory settlement.

Copyright in Group Photograph.—In May last I asked permission of the president of a local club to photograph the team. The president was photographed in the group with the boys and afterwards paid for and presented each boy with a copy of the photograph. A fortnight ago, a local shoemaker who occasionally takes photographs as a professional obtained a copy of the photograph and made an enlarged photograph, towards the cost of which each boy contributed a small sum. This enlarged photograph, when framed, was presented by a member of the committee to the president on behalf of the boys. Is this an infringement of copyright, or is the shoemaker justified in his action?—N. E.

If it is perfectly clear that you went to the president of the club and said to him, "I will take a group, and it is all the same to me whether you buy copies or not; you need not buy them unless you like," then, without any question at all, the copyright is yours and the shoemaker has infringed it. On the other hand, supposing the circumstances were something like this, namely, that you canvassed the president for an order and that there was an understanding, either expressed or implied, when you photographed the group, that you were doing so because you were going to supply copies to him at so much each, then (although the circumstances are not quite as clear as they might be) we think that the president might be said to have given you an order in response to your request. In this case the copyright is his. The shoemaker has still infringed the copyright, unless he has made his copy with the permission of the president, but any ground for action in this case rests with the president and not with you. In either case the owner of the infringed copyright can, if he wishes, take action against the infringer in the County Court for delivery of all the infringing copies and the negative from which they were made.

JOURNAL OF PHOTOGRAPHY.

No. 3248. Vol. LXIX. FRIDAY, AUGUST 4, 1922. Price Fourpence.

Contents.

SUMMARY.

The first of a series of papers, entitled "With a Portraitist in the Studio," appears on (P. 459). These articles are written by a practical worker of unique experience whose aim is to give to the studio worker the kind of help he would get from an experienced portraitist by his side at the time of operating.

Grain structure versus light quanta in the theory of development is dealt with by Mr. W. Clark, B.Sc., in a communication from the British Photographic Research Association Laboratory. (P. 462.)

While it is not recommended that the unskilled should take the responsibility of restoring a tarnished Daguerreotype, the process is one which can be easily carried out after a little experience. We deal with the practical details in a leading article on (P. 458).

In considering the purchase of a reflex, the photographer may form too high opinion of its capabilities in some respects. On the other hand, he may overlook the preventives of common errors in the use of a hand camera which it automatically affords. (P. 457.)

For avoiding reflections in the copying of coins and other small articles of metal, several methods can be used for temporarily dulling the metal surface. (P. 458.)

While the addition of ammonium chloride to the hypo bath renders fixing much more rapid, it is doubtful if a bath of this kind has any practical advantage except for exceptionally "rush" negative-making. (P. 457.)

Messrs. Wellington and Ward, Ltd., have acquired the business of the Leto Photo. Materials Company. (P. 467.)

Tidiness in trimming a large number of small prints, and a handy accessory into which the different sizes of prints may be sorted as they are trimmed, are dealt with in an illustrated paragraph under "Assistants' Notes." (P. 464.)

The Derby Photographic Society, which has been derelict for some years past, has been revived. (P. 467.)

A machine for drying blue-print paper, and a new pattern of ferrotype camera, are described in recent patent specifications. (P. 465.)

Two correspondents write with reference to Continental negative varnishes, giving formulæ in which benzene is used. (P. 468.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

An ingenious process has been patented for the conversion of a colour screen-plate transparency into a three-colour print by chemical treatment of the special mixtures of dyes used for the colour elements in the mosaic screen-plate filter. (P. 29.)

Many interesting historical and technical details concerning the once popular Kinemacolour colour process of cinematography are given in a contributed article on (P. 30).

A new arrangement for showing the formation of white light by a mixture of red, green, and blue-violet, and also of all the colours of the spectrum, is described on (P. 32).

EX CATHEDRA.

Extra-Rapid Fixing. When we hear, as we occasionally do, of fixing baths which are claimed to be extraordinarily more rapid in action than those of hypo, we suspect a mixture of hypo and ammonium chloride, which combination was patented years ago by a German chemical firm and placed on the market. The mixture, when first taken into use, certainly does fix more rapidly than hypo, and on that account has its value for the making of negatives in the minimum of time. Yet it cannot be said that in regular use it presents any advantages over a fairly strong hypo solution, *e.g.*, one containing 6 ozs. of hypo in 20 ozs. of water. Indeed, MM. Lumières in their experiments came to the conclusion that in the stage of partial exhaustion the mixture was less efficient as a fixer than a plain solution of hypo of corresponding strength. Nevertheless, for rush work the mixed fixer of hypo and ammonium chloride can render a useful service, and those having occasion to use it for such purposes cannot do better than employ the formula which the late Mr. Welborne Piper found to be the most rapid in action, viz., hypo, 4 ozs.; ammonium chloride, ½ to 1 oz.; water, 20 ozs. This bath fixes in about half the time required by one of the same strength in hypo, and is, we think, as rapid a fixing solution as can be made.

* * *

Why a Reflex? The hand-camera user who contemplates the purchase of a reflex naturally sums up in his own mind the advantages which he will obtain in return for a sum of money which, at the least, is not small. In doing so, he may form too rosy an opinion in some respects, yet one which does not do sufficient justice to the reflex in others. In regard to the facility and certainty of composing and focussing the picture on the ground glass there can be no doubt; the reflex stands alone in providing the means of sharp focus at a large aperture, even with a long focus lens, and likewise of making as sure of the boundaries of the picture when the front is raised as when it is central. Nevertheless, the would-be purchaser may be misled into supposing that it is practicable to keep a rapidly-approaching subject in focus on the ground glass by operating the focussing pinion. It may sound feasible, but practice shows that a pre-chosen spot must be focussed on and the shutter released when the subject reaches it. On the other hand, there are, perhaps, certain minor merits of the reflex which are apt to be overlooked. One of these is the safeguard against misfires (the shutter unset) which it provides. Habit being what it is, it is pretty certain that if the mirror is in the down position, so that the picture is visible in the hood, the shutter has also been set, and hence one is prevented from missing a subject through omission to set the shutter, as may sometimes happen with an ordinary hand-camera. This feature, it must be mentioned, is possessed only by the reflex with

spring-raised mirror, requiring to be put down after each exposure, a type of reflector camera which, for other reasons also, is superior to one in which the mirror falls of itself after each exposure. The quickness of dealing with a subject is another point in favour of a reflex. Another, is the realistic image which is seen; and still another, so some users have assured us, is the guide to exposure afforded by the brightness of the picture. In our judgment and experience, however, there is little to be said for the last-named.

* * *

Copying Medals. In overcoming the reflections which are a source of difficulty in the photography of coins, medals, and similar small articles of metal, the photographer having an air-brush at disposal will spray these originals with a thin film of grey colour. Those, however, who have not an air-brush may obtain as perfect a result by adopting the plan, which we believe was first suggested by Mr. Harold Hood, of depositing a fine coating of magnesium oxide on the articles by burning magnesium ribbon a few inches below the surface of the medal, held in an inverted position. For then holding the coated medal in position for photographing, a most convenient plan is to cut a hole in stout millboard, roughly corresponding to the shape of the medal, but slightly smaller. The piece of millboard is then cut in half, the medal laid down on the copying board, and one-half of the millboard placed closely on each side of it. The two halves are then pinned down with drawing pins and hold the medal fast, without any liability of shadows being cast upon it, as may be the case if it is supported by means of pins of any description.

THE RENOVATION OF DAGUERREOTYPES.

Specimens of the Daguerreotype process are things which not infrequently are brought by customers to a photographic studio under the quite justifiable belief, on the part of their owners, that a photographer necessarily knows all about them and can restore them. We are afraid that this confidence is not always well founded, and, in fact, we have frequently received from professional photographers specimens which were alleged to be Daguerreotypes, whereas, in fact, they were collodion glass positives. Failure to distinguish between the two can arise only from complete ignorance of the two bygone processes. For the specimens themselves are instantly distinguishable. The Daguerreotype, of course, is on a metal plate, whilst the collodion positive is on glass. Inasmuch as a photographer, for his own sake, will not wish to confess his inability to do what is possible in the way of restoring such specimens as these as have faded, and since, moreover, commissions of this kind frequently lead to fairly good orders for copies in the shape of prints or enlargements, we may, perhaps, bring together a few practical notes on the methods of restoring. There is no special difficulty in the work; nevertheless, it should be undertaken at the owner's risk. Those who do not feel disposed to do it themselves can still obtain the services of professional restorers of these plates.

In the first place, it is necessary to satisfy oneself of the nature of the specimen—Daguerreotype or collodion positive. As already said, the support of the image immediately identifies one or the other. Apart from the fact that the two classes of specimen require different treatment, it needs to be borne in mind that the collodion positive is a much more fragile and easily damaged thing, the collodion film becoming, in many cases, almost powdery with the lapse of time so that a touch of the finger or the slightest friction in removing a cover glass may damage the portrait irretrievably. When it is ascertained that the specimen consists of a collodion film on glass, by far the best plan is to decline any attempt at renovation, and to suggest to the customer that the specimen may be copied and reproduced as a print or enlargement in, say, the platinum or carbon process.

In the case of a genuine Daguerreotype, on the other hand, restoration does not call for a great amount of skill. A very little practice with one or two old plates, such as often can be picked up for a small sum in shops selling small miscellaneous second-hand goods, is necessary in order to become adept in the work. Two different processes are employed. In one, the Daguerreotype is treated with a weak solution of potassium cyanide; in the other, devised and recommended by Mr. W. E. Debenham, the plate is treated with hydrochloric acid. We believe both processes are equally effective, but as our experience has been confined to the former we will deal with the practical details of it.

The metal plate, having been removed from its case, and any particles of paper binding removed from the back, the first thing is to remove any dust on the surface by rinsing under a gentle stream of water from the tap. Although the Daguerreotype image cannot be rubbed off by ordinary means, the specimen can be easily scratched, even by the use of a brush. The surface is now flowed over several times with industrial methylated spirit, that spirit is free from mineral naphtha. The ordinary methylated spirit of the drug store should not be used; if the industrial spirit is not readily obtainable the much more expensive spirit of wine is used, a quite small quantity being required.

The plate is now placed in water, and in another dish a weak solution of potassium cyanide is prepared. A definite strength for this latter cannot be specified, owing to the differing degrees of purity of commercial cyanide. A 10 per cent. solution of the commercial cyanide is made and a few drops of this stock added to an ounce or two of water in the dish. This working solution may then be strengthened as is found necessary by adding, a few drops at a time, more of the stock solution. It goes without saying that this addition should on no account be made to the bath while the plate is immersed in it; the further cyanide should be dropped into a graduate, the bath poured back into the latter and then re-applied to the plate. The action of this solution is gradually to remove the tarnish which has caused the so-called "fading" of the picture. At the same time the action must not be overdone, since the cyanide, if given sufficient time, will act upon the picture itself. As soon as the picture is seen to be cleared, the plate is well rinsed back and front under the tap, and now requires only to be dried and replaced in its frame. Drying, however, is an operation which requires to be done carefully in order to avoid the occurrence of streaks or lines which would deface the picture. The most convenient source of heat for the purpose is an ordinary Bunsen burner, as supplied for chemical laboratories, fitted with a rose cap, and thus giving a ring of minute gas flames about 2 inches in diameter. The plate is held by a pair of pliers at, say, the left hand bottom corner, and allowed to drain for a minute or two whilst perfectly still. The top corner is now brought gradually over the burner, and as the plate shows signs of drying it is slowly raised so that the drying proceeds evenly downwards. The object is to secure a regular rate of drying diagonally across the plate, thus avoiding markings or lines. It then only remains to bind the plate with its original cover glass, using a good lantern-slide binding strip or a thin, tough, plain paper in conjunction with ordinary starch paste.

WITH A PORTRAITIST IN THE STUDIO.

[Under the above title there will appear a series of papers by a professional portrait photographer of long experience Mr. J. Effel, whose aim in writing them has been to give to the studio portraitist, as far as possible, the kind of help which he would obtain by the personal guidance of a competent portrait photographer by his side at the time of posing and lighting the sitter. Each article will be complete in itself, but it will be to the student's advantage to consider one in relation to another. As far as possible the papers will be published week by week.]

I.—INTRODUCTORY.

Some years ago, when outlining my ideas of making photographic portraits by a systematised application of definite principles, I was met by the fairly obvious objection that the results of my teaching would be a uniform output of mediocre work. Originality would be completely destroyed; the student would merely glance at his unfortunate sitter, look up his lessons, then briskly proceed to take the portrait according to the instructions.

I was quite prepared for the objection of my friend—an artistic worker of undoubted ability—but I am pleased to say that I converted him to my views, so much so that we now regularly criticise each other's work "by the book."

It is always a safe plan for the revolutionist (in art as in political economy) whose new theories are viewed with scepticism, to point to the state of matters *now*. While it is indisputable that the work of leading photographers to-day far transcends that of a generation ago, it is also true that there are hundreds of studios whose productions from year to year are entirely devoid of any interest whatever, where business is in a chronic state of slackness, and the miserable proprietors tell us that photography is no good nowadays, that the public don't know a good thing when they see it, that they don't know what they want, and that the amateurs have ruined the profession.

Well, it must be admitted that our business is not booming at present; but, unfortunately, there are many others harder hit by the general depression, and I don't think the grumblers are justified in their pessimism. I believe that the principal cause of bad business is indifferent work. If the public have no very clear ideas of what they think good work, they are under no illusions as to what they *don't* like, and they invariably know a *bad* thing when they see it.

To improve the standard of professional portraiture, to give the young photographer definite standards of art values, to systematise all the knowledge and methods of the best craftsmen, to so simplify guiding principles in the production of pictures that the public will appreciate, these are the ideas behind these articles. I will deal with my subject in as simple and popular a manner as possible, in fact I am really writing for those workers who, skilled enough on the technical side of photography, don't know how to improve the artistic quality of their work. Knowing that, in these days of dear plates, very few portraitists can afford to take many positions in an endeavour to satisfy a client, I have constantly kept in mind the man who has to get twelve pictures out of a dozen plates, and satisfy twelve different sitters. I will endeavour to coach you up to a point when you will be able to "weigh up" a subject at once, and, without any fumbling, select the most suitable point of view, the most appropriate lighting, the general tone of the picture.

"But doesn't that make for the stifling of all individuality?" I think I hear you say, and I may be told that a work of art cannot be constructed as a table might be by a joiner after consulting a book of rules.

Well, as it is just this wearisome sameness of "the usual thing" that I am trying to kill, it is unlikely that I would wish to destroy initiative. All I claim to do for the student who desires to create a work of art is to give him in as concise manner as possible, those methods of artists in figure drawing and painting which are applicable to photography. I am certainly nothing of a dogmatist. I believe with Bernard Shaw that the golden rule is that there is no golden rule. We frequently hear that genius breaks all laws, but a close observation of their works has shown me that men of genius were invariably masters of the rules of their craft to which they closely adhered. Now no teacher, whatever his system can make an artist of one devoid of feeling, but, assuming that the young photographer I am addressing has a modicum of taste and some appreciation of beauty, I can help him to get more joy out of his work as well as more profit.

To begin with, we all make our portraits by method. We have fairly definite ways of taking a clergyman, a soldier, a lady in evening dress, and when it comes to physical differences we are also pretty definite, both as to what we wish to show and what we wish to conceal. The well-dressed lady with a classical figure suggests a full-length standing, a simple pose, and an absence of accessory. We know that the stout, ungainly person looks worst sitting back in an armchair, for we want to give the impression of length not breadth. We instinctively over-expose the very freckly face, we never take the man with protruding ears full face, and so on. I merely wish, then, to extend the principles on which you already work, so that you may be thoroughly equipped for any problem that may confront you in the studio.

The broad distinctions I have instanced are obvious enough, but when we have to deal with types not strongly marked, or very ordinary looking individuals who defy accurate classification, the problem of selection becomes more complex. It is said with truth that to do more one must *be* more. Certainly in photography to do more one must *see* more. Quite two-thirds of the whole art of portraiture consists in seeing what there is to be featured: no degree of skill with brush or camera can compensate for deficiency in this respect. Get into the habit of accurate observation. Keep constantly regarding the people you come into contact with daily. Notice the old man sitting opposite you in the tram; see how the blink of sun gives a fine "Rembrandt" light to his face, and think how that effect can be reproduced in the studio. See that comfortable motherly-looking creature with her hands clasped awkwardly on her lap, and note how, with a slight turn that would not interfere with the naturalness of her **attitude**, the hands could be rendered far less obtrusive. Observe the dress, the demeanour, the mannerisms, as well as the figure and features of your friends. Keep constantly looking for something different, even in the most commonplace of persons, and you will be surprised at the infinite variety you will find.

Above everything else study expression, and try to forget the conventions of the studio. Look at the fond mother goo-goo-ing to her baby. Is it fair to complain if she doesn't like the "still life" group of a professional, and prefers the little snap taken by cousin Tom when Sunnums was trying desperately to pull off Mumma's heads?

Let us realise quite frankly that the amateur—even the merest beginner—has this advantage over us, that his portraits are of his intimate friends, that the subjects are seldom posed, are not dressed up for the occasion, and are frequently

taken without their knowledge. Small wonder, then, that a large percentage out of the multitude of snaps have an enduring charm. Looked at in the proper light, the slight "pull" that the amateur has over us should lead us to the scrapping of the artificiality that still clings to most studios, and help us to realise that *the production of a likeness is the first duty of a portrait photographer to his client.*

To put a little method into my own philosophy. I will now ask you to suppose that I am instructing a young assistant. George has served an apprenticeship, and is a capable general assistant, but his knowledge of operating is merely the ability to "take a negative in the absence of principal." George has no art training, but has a keen appreciation of beautiful things, a love for his work, and a keen desire to make good. George and I will now proceed to the studio, and the practical work of taking photographs for the public.

II.—THE BUST PORTRAIT.

Now, George, we are to consider every factor in the production of a portrait, from the filling of the dark slide to the drying of the negative. And that reminds me. Yesterday, when you were filling the slides of the field camera, I saw you run your hand over the film of each plate, the object, I believe, being to take off dust. Nearly every photographer does some caper of this sort, rubbing the plate with his hand, or a camel-hair brush, blowing on it, or knocking the edge on the bench. Think a moment of the dusty changing rooms you have seen, and of the conditions prevailing in a plate factory, and then ask yourself if the plates are not more likely to be dust free when newly taken out of their wrapping paper than after an assistant pawing at them in our dark room. I have known an old hand open a new box of 15×12 plates, very carefully dust each one, then fill them into slides that had not been used for months! This plate dusting is a superstitious survival, and should be discontinued.

We are first going to devote our attention to the head and shoulders or bust portrait. In a sense it is the simplest of all portraits, the artist having to consider so little of the figure, but for the same reason the attention is concentrated on the face, and one has, therefore, to be more exacting with the lighting and expression than in a portrait where the interest is more general.

Before we get a model it will be as well to understand clearly the terms used and their significance. All terms are relative. What is called a side light for a certain subject may be a top light for a different position; a narrow light may become a broad or full light by altering the placing of the sitter or the camera. I will, therefore, give a few rough definitions, which will save me from always qualifying myself.

Side Light.—That part of the light source which illuminates the subject from one side and slightly in front, but which in itself does not usually complete the lighting scheme.

Top Light.—Same as side light, but higher.

Front Light.—Light which falls on the sitter illuminating both sides of the face evenly in a flat, shadowless way. The light largely employed by miniature painters.

Back Light.—Comes anywhere behind the sitter, and is generally employed to supplement the general lighting and to pick out prominent features.

"Rembrandt."—Lighting where the major part of the picture is in shadow. Line lighting and spot lighting are in the same category.

Now, George, we will start our experiments with Mr. Black (my head printer). Which is the better side of Mr. Black's face? Yes, without doubt, the left side. Then that matter is settled. It has become an axiom that the left side is the better one in most cases, and most studios are used with that idea. Shall we take him with the usual soft lighting, or shall we try something of the Rembrandt nature? Most photographs are taken with the head turned away from the light. Experience teaches us that this is the safer way of making portraits for the public, but I want you to see the reason for this. Portrait painters are not hampered by the idea of making their sitters look away from the light, but here let me just point out the fundamental difference between the painter and photographer occasioned by colour.

I spoke of the miniature painter's light. Photograph a sitter with the lighting that gave a charming effect in colour and you will find it quite uninteresting. The delicate nuances, the subtle shading, the intermingling of tints, are destroyed when rendered in black and white and the feeling of roundness destroyed. Broadly speaking, in photography the lighting should have more vigour and contrast than if the picture rendered the colours. Don't waste plates without knowledge. You must train your eye to appreciate effects, and also accustom yourself to allow for the inevitable discrepancy between what you see in full colour and what the rendering will be when translated into monochrome. Get it firmly into your head that until the composition *looks* right it can have no chance of coming right in the negative. Many workers prefer to study the effect on the focussing screen, and certainly one sees nothing there to distract from the picture. The habit should be cultivated, however, of getting the whole arrangement ready before looking at the camera.

Now let us get back to the consideration of the lighting of our subject. Some photographers work always from the same end of the studio, but when it has been decided to feature one side of the sitter that limits our choice of lighting. Few rooms are so built that a bust could not be taken at either end. Don't hamper yourself in any way. Put your foot through all the conventions when you feel strong enough. Work experimentally all round the room, for you can never have too much variety at your command.

Your choice of lighting should be determined by the features or the projections of the face. Irregular features, or the plump, round face with low projections (small nose, etc.), except in the hands of a skilled worker, should be taken looking from the light. As very few of us have classic features, it is easy to see how the traditional lighting came into being, for a portrait in which the subject is turned towards the light is much more exacting to the sitter and more difficult for the photographer. You will find a fascination in thinking out your lighting in terms of the projections of the face. Think for a moment of two prominent public men whose features are known to everyone—Lord Carson and Mr. Winston Churchill. They are very dissimilar, but both are faces of great character and distinction from any angle. To me, however, if I had to economise plates, the nose and chin of Lord Carson demand side-face treatment, and could stand the boldest of lighting, while Mr. Churchill's rounded face and absence of definite lines would make me seek an entirely different style of portrait

We are not going to try anything ambitious with Mr. Black. Just sit down there, please, and let us analyse your face—in the interest of art, you know. You see, George, that the studio is dark; I always begin this way, and let in light as wanted. The great fault with most galleries is that there is too much glass. This studio was built in the old days of slow plates, but as you see, I have the light well under control. It matters not what system of blinds one favours, the essential thing is to be able at will to admit all the available light, or to let in a square foot only, from any part. Now, what is there about Mr. Black that we wish to show, and what are his weak points pictorially? Oh, don't' be afraid; Mr. Black is too sensible to be offended by my remarks when I am giving demonstrations. And, by the way, George, don't ever get into the way of thinking that only with well-dressed,

handsome subjects can artistic pictures be produced. Even a third-rate artist could get a specimen of Gladys Cooper, but the little shop girl, who fancies herself as a rival to Mary Pickford, looks for, pays for, and ought to get something that will show off her charms to the best advantage. Practice selection, and you will be surprised at the beauties you will discover in the commonplace.

Mr. Black has a poor chest. He doesn't want to immortalise this fact, so we will give him all the breadth that we can. Just as he sits there in the chair will do. The arms are too close to the body, giving a sense of weakness. Look always for this in your sitters, women as well as men. Get them to stick out the elbows a little, and when the lines of the arms slope outwards the figure is greatly strengthened. If we were to take Mr. Black looking to the front it would be necessary to turn his shoulders away slightly, as nothing looks more wooden than a portrait with head, body and eyes all in the same direction. I decided against the right side of our subject's face because his mouth droops more at that side and his cheek is sunken in from the loss of teeth. Turn your head slighty away from the light, Mr. Black. The longer the neck, George, the more one may turn the head. There are two ways of shortening a neck—turning the head as much as possible without strain or heightening the camera. A stout, short-necked person should never be turned much, and the camera should be lower than usual. A great fault with busts is a too high camera. As we turn Mr. Black's head you will see the broken line of the bad cheek silhouetted against the background. Keep turning until you lose this as much as you can. Mr. Black's face is not one for profile treatment, the head and nose are shapely, but the chin is weak. There, now, I think we have a point of view that would give his friends a "speaking likeness," but there is not sufficient light. We will consider that problem.

Think of the face as a physical geography map and try to render all its hills and dales and different planes (a subtle pun there, George) so that your picture gives the feeling of roundness and "stereoscopic" effect. Remember that the camera is limited, having only one eye; I would again say in this respect slightly exaggerate your effects in lighting to make up for the inevitable loss. Most bust portraits have too much light. One can retouch the face with light and take all the character out in the studio, with bad lighting, just as an incompetent retoucher does on the negative. When you consider that about two square feet will cover the interest in a bust, you will see this. Mr. Black has hollow cheeks; if the light is too much from the side there will be an exaggeration of this defect, too much front light, and his cheeks will be unnatural. If you wish good "modelling" in your work be very sparing with front light. A negative with the hollows and lines over-accentuated can be considerably modified in the retouching, a negative where all the features are reduced to one plane is hopeless.

Think always of the age and disposition of your sitter. Mr. Black is not a young man, and doesn't want to look like one, but although age has left her mark on his face, he wants to look his best. Flattery is good business, but it must be used with discretion, for few intelligent persons wish to look like wax figures. Now look at Mr. Black's head. Men of our age, when their hair is thin and grey, are apt to be sensitive. Top light shows us at our very worst. Keep the light low for our subject. Just a moment, George, till I make my meaning clear; let in a good streak of top light and see the billiard-ball effect of the forehead, and also notice how the small chin is in shadow and looks even smaller. This is the exact wrong lighting. Keep careful watch over the effect while I readjust the blinds. See how the chin comes out, the head loses the dome effect, and the wrinkles are less like tramway lines. You can soon learn to "retouch with light" by regarding a sheet of corrugated paper and noting the shadows cast by the wrinkles, in different lights, with the lines perpendicular at one time and horizontal another.

Well, there we have our respected foreman ready to be "operated" on—horrible word that, George, I wish someone would invent a better. Do you suggest any modification of the scheme? A little too dark on the shadow side? Glad you mentioned that; that shows observation. Now it is a trifle dark on the far side, but I did that purposely. So far we have made no mention of the background, contenting ourselves with the screen that was last in use. Yet the tone of the background plays a part in the composition that cannot be ignored.

The essential function of a background is to afford contrast to the figure, but it can also be used to hide unpleasing features. Take a completely bald head, place behind it a black screen, and you have a monstrosity. Take another of the same subject, with a ground as near the tone of the head, so that the one merges into the other, and the result will give infinitely more satisfaction. It was on that principle that I left the shadow a little dark on Mr. Black. Bring up the reflector and watch the model all the time. Now don't you see that with the shadow softened the broken line of the cheek stands out too much? That's why I preferred to "lose" the outline in the background. I shall have a lot more to say, when I come to treat full lengths and groups, about the choice of suitable grounds. Meantime, focus this very patient subject and I'll expose the plate.

Now, Mr. Black, this is for the male beauty competition, you know—ah, that's the trouble over. See that negative developed to-night, George, and we'll go over the points again to-morrow and see if we have been successful. Before you go, Mr. Black, I want George to notice the last thing I consider in a portrait, and the one that is of supreme importance—the eyes. I was too busy tricking Mr. Black into a happy expression to lecture you on this point. I just wish to draw your attention to the direction in which the eyes are looking. Many pictures are spoiled by the photographer not knowing definitely where the subject should be looking; in sitting figures the fault usually being that they look too high. This is explained by the fact that the photographer is standing when making the exposure. You noticed that I sat down to snap Mr. Black. Keeping him in conversation, and knowing that his eyes looking to me gave the right direction to them, I was saved the "look at this object and smile" method. Try hard to forget all these well-worn tricks, George.

Now for the determining factors in the direction of the eyes. If you have difficulties with a client, don't experiment or fumble. Consult me afterwards, or reconstruct the problem with a model, but get certitude, always give the impression that you are master of your technique. Just stand up, Mr. Black, and look straight to the camera. Now slowly turn your head round to the right. Round, round you go; go on, further round. What's that? You can't twist any more without shifting your feet? Quite right, that's just the point I wanted to bring out. Well, thank you, Mr. Black, I'll come down presently and select those whole plates for toning. Now what was that turning performance for, George? I wished to show you the sequence of the various movements that have taken place. A figure at "attention" with "eyes front" slowly turns round. The eyes move first, the head next, then the body, and the feet a reluctant last. In all pictures suggesting movement this formula must be adhered to. Except for the expression of certain emotions, *the eyes should always be looking slightly in advance of the direction in which the head is turning.*

We'll come back to most of the points in future lessons, George, but before finishing this morning, let me ask you to go over in your mind the many factors to be considered in the making of a simple head-and-shoulders picture. Only by assiduous study, co-ordination of all your knowledge of the craft, and persistent practice on lines suggested by your newly-acquired information will your work improve. I hope I have helped you somewhat away from uncertainty and towards method.

J. EVVEL.

GRAIN STRUCTURE *v.* LIGHT QUANTA IN THE THEORY OF DEVELOPMENT.

(Communication No. 24 from the British Photographic Research Association Laboratory.)

Recent investigators have shown that the developability of the silver halide grains in a photographic emulsion is due to the existence on their surfaces of some kind of "reduction centres" which are distributed amongst the grains according to the laws of chance. Opinion is at present divided as to what these centres actually are, or how they are formed. Some take the view that the centres exist in the grains from the time the emulsion is made, the function of the light being merely to change their condition in some way. Others believe that the centres are first formed by the incident radiation, and that they do not exist in the grains as specially sensitive points before exposure. Some even suggest that these "reduction centres" are the actual points of impact of discrete light-quanta. This view was taken by Lowry in the discussion following a recent paper of Svedberg's ("Phot. Jour.," 1922, 62, 193). The idea of the bombardment of the grains by discrete quanta is the basis of an exhaustive mathematical theory of photographic exposure in a recent paper by Silberstein ("Phil. Mag.," 1922, 44, 257), published since the experiments to be described were completed.

It seemed of extreme importance to attempt to render these "reduction centres" visible by some means not involving the action of any kind of radiation, and to study the laws governing their distribution. Experiments were therefore commenced early in this year, and were based on the results obtained by Bancroft, Perley and others ("J. Physical Chem.," 1910, 14, 292, 648), who found that a dilute solution of certain reducing agents will affect a dry plate in such a way that the silver bromide can then be reduced by the ordinary developer under the usual conditions. This is the case with such reducing agents as stannous chloride, sodium arsenite and hypochlorite. (Cf. also a later suggestion of Renwick, using hydrogen peroxide, "Phot. Jour.," 1922, 62, 196.)

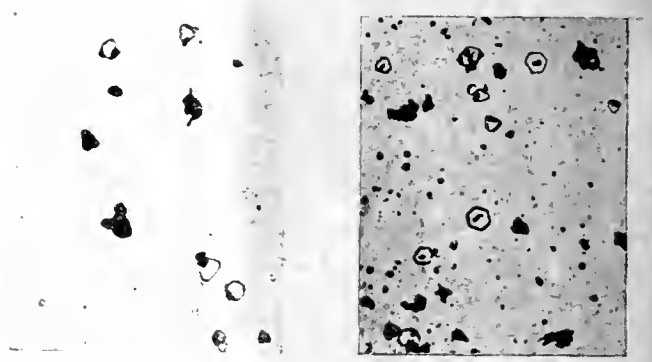
Preliminary qualitative experiments were carried out with stannous chloride and sodium arsenite in 10 per cent. solution. Stannous chloride was found to affect the gelatine of the plate, causing it to become brown, and difficulty was experienced owing to the hydrolysis of the salt. Attention was therefore confined to the sodium arsenite, which gave clean results, free from apparent action on the gelatine. Strips of an ordinary commercial ultra-rapid plate were soaked for varying times in a 10 per cent. solution of sodium arsenite and then washed, developed in amidol developer, and fixed. Images were thereby obtained without light-action. The density of these increased with increase in time of exposure to the arsenite, up to a maximum, further exposure producing reversal. This confirms the work of Perley (*loc. cit.*).

Attempts were then made to see whether the development of the silver halide grains after treatment with sodium arsenite solution proceeded in the same way as when light is used, or X-rays, for rendering the grains developable. Single-layer plates were prepared from a commercial ultra-rapid plate in the manner described by Slade and Higson ("Proc. Roy. Soc.," 1920, 98, 158). The grains in the emulsion were mostly flat plates, and varied in area from about 0·5μ^2 to 5^2 The emulsion used was the same as that employed by Toy in his experiments, the results of which are to be published in the "Phil. Mag." (in the press).

The single-layer plates were treated with sodium arsenite solution, washed, partially developed in amidol developer (Amidol-0.4 gm., soda sulphite saturated solution, 100 c.c.s., potass. bromide, 10 per cent. solution, 6 c.c.s.), and again thoroughly washed. All these operations were carried out in ruby light (the filter used transmitted light only of wave length greater than 6,400 A.U.), the plate being shielded from the red rays as much as possible. The conditions for the production of a plate suitable for examination were 30 secs. exposure to 10 per cent. sodium arsenite solution, washing for 3 minutes and developing for 42 seconds.

With the above exposure to the reducing solution there was very little lattitude in the time of development, a few seconds one way or the other causing the grains to be either completely changed or unaffected.

In dealing with a liquid such as sodium arsenite solution accurate control of exposure is more difficult than in the case of light, since the time of diffusion of the solution to and from the gelatine of the emulsion is an important factor, and any inequalities in the coating of the plates will tend to give non-uniform exposure. In the present experiments the solution was kept constantly in motion over the surface of the plate while the exposure was being made, and the coating on the plates used was exceedingly thin. The plate obtained as described was examined in the microscope. A few of the



a *b*

Fig. 1.—(*a*) Exposed to light (*b*) Exposed to 10 per cent. sodium arsenite solution. Both (*a*) and (*b*) are partially developed.

grains were observed to be completely changed, but the majority showed centres, in appearance, exactly similar to those obtained by Toy when the exposure is to light (see Fig. 1).

The distribution of these centres among the grains was then examined in the manner used by Svedberg (*Phot. Jour.*, 1922, 62, 186-192) and Toy (*loc. cit.*). These investigators, the former for light and X-rays with a slow emulsion, the latter for light with the flat grains of a very fast emulsion, have shown that the "reduction centres" are distributed amongst the grains according to the laws of chance; that is, the probabilty for the occurrence of r centres in a grain is denoted by

$$P_r = \frac{(N_0)^r}{r!} e^{-N_0} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where N_0 represents the average number of centres per grain. 400 grains were examined and the number of centres on each grain counted. The probability of occurrence of r centres on a grain was calculated from the observed figures by dividing the number of grains each having r centres by the total number of grains. The grains counted were of approximately triangular shape and all of the same size (area of flat surface=2.73μ^2; *cf.* Toy). The results which

were obtained are shown in the following table; they are plotted in fig. 2 against the theoretical curve of equation (1).

Number of grains counted = 400.
Total number of centres = 764
$N_1 = 1.91$.

Number of Centres per grain = r.	Number of Grains.	P_r	
		Observed.	Calculated from equation (1).
0	89	.172	.148
1	111	.277	.283
2	100	.250	.270
3	57	.142	.172
4	39	.097	.082
5	19	.047	.032
6	4	.011	.010
7	1	.0025	.0027

When the difficulties which occur in such experiments, especially those in controlling the exposure to the arsenite solution, are taken into account, the agreement between observed and calculated values is very satisfactory; it is even better than that obtained by Svedberg with light and X-rays.

It has been shown by Toy (*loc. cit.*) that in the case of the flat grains used by him the ratio of centres occurring on

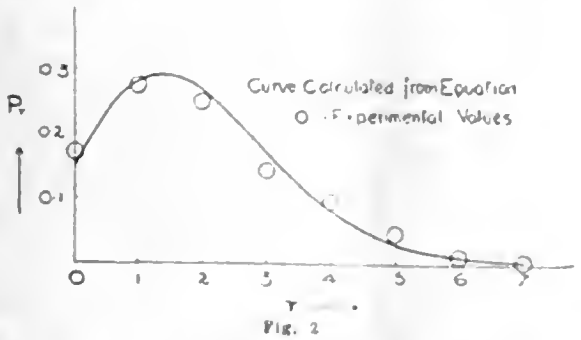


Fig. 2

the edges of the grains to those either on the flat surface of the grain or inside it was approximately 2.5 : 1 when the exposure is to light. Similar measurements were made on the single-layer plate which had been exposed to sodium arsenite. The grains investigated were of the size 2.73 μ^2 as before, and the results obtained were as follows:—

Number of grains examined = 70.

Number of centres on edges of grains = 67.

Number of centres inside and on flat surface = 29.

Ratio of centres on edges to centres inside and on the flat surface = 2.3 : 1.

It will be seen that the ratio thus obtained is in good agreement with that obtained by Toy with light and grains of the same size and from the same emulsion.

It seems, therefore, very probable that the reduction centres made visible by means of the chemical reducer, sodium arsenite, and subsequent development are the same as those which would be observed if light or some other form of radiation had been employed as the means of rendering the grains developable. The centres located by means not involving the action of any kind of radiation follow exactly the same law as regards distribution among the grains, and also as regards the topographical distribution of the centres on the individual grains themselves. The only other possibility for the reduction of the silver halide from specific points appears to be merely that the developer reaches one part of the grain before another. This has been discussed by Toy (*loc. cit.*) and shown to be untenable.

The above results, therefore, indicate that the reduction centres are an essential part of the grain structure, and that they exist in the grains from the time the emulsion is made. The action of radiation is certainly not necessary for their formation, and the idea that they represent the points of impact of discrete light quanta is not in accordance with the experiments here given. What the actual nature of the reduction centre is, and how it is rendered active by the action of light and of chemical reducers, remains to be seen. Investigations in this direction and a continuation of the experiments described are now being carried out in this laboratory.

In conclusion, the author wishes to express his thanks to Dr. T. Slater Price (Director of Research) and to Mr. F. C. Toy for their interest in these experiments and for much valuable criticism and advice.

W. Clark, B.Sc., A.I.C.

Assistants' Notes.

Notes by and for assistants will be considered for this column. Payment for accepted contributions is made on the first of the month following publication.

On Getting On.—For Young Assistants.

One often hears and reads about great men, captains of industry, statesmen, judges, admirals, etc., who were totally incapable and worthless as schoolboys; and also of brilliant scholarship champions who left school or university to go rapidly to the dogs. Now, the truth in this and there is a certain amount—applies to men in most ranks of life, and to photographers, but in the last case it applies in a modified degree.

The bright, intelligent boy who enters the photographic trade or profession has not the slightest need or likelihood of being left behind by the dunce if he will remember just one or two things. And the slow-thinking plodder need not win the biggest success any more than he need go to the wall. But each boy or girl must believe me when I say that he or she will be the biggest factor in his or her success or failure.

I have had a fairly comprehensive experience of junior assistants and apprentices in my time, and I think I can best make plain what I am getting at now by taking an example that has occurred. A certain youth, whom I will call Felix because that wasn't his name, was promoted from running errands to assisting in a small dark room, where he would have every opportunity of learning, but not much work. The fact was he was considered too brainy altogether to be wasted on messages. He very soon proved that he was brainy, really so, and had an aptitude for the craft. In a week he had bought himself a small camera. Soon after that he could take a really good portrait photograph. Things developed till he was photographing his relatives and selling them copies; in fact, I have never come across equal at rapid photographic success.

But, alas! he got the sack. Why? Because it is not possible for a boy to study even his own profession to such an extent in the boss's time and look after his job as well. Our friend was too brainy, inasmuch as he could not be convinced that the work given him to do was far and away more important than the work he felt like doing himself. Consequently, things were forgotten, other assistants suffered through his errors and omissions, and finally the boss got "fed up."

When he was promoted, another boy—we'll call him Jacob—was given the "errand" vacancy. Jacob was a totally different style. He, too, had a camera, but couldn't use it for toffee. But he was good at errands; never wasted any time, didn't stay out when any local festivities were on in an endeavour to get Press photographs. Jacob was content to do what was allotted to him, and do it well. After that he did nothing. Not that he was mechanical. He had some brain, certainly, and within reason he used it, but when he was given the same promotion that Felix had wasted he was never guilty of turning his back on a dish of developing prints in order to try to talk panchromatism. He followed instructions intelligently, and was quite content to learn as he went along. Jacob did well.

The moral will, I think, be plain. Talent, and even more so, genius, is valuable in photography, but it must be kept in hand and controlled. The acknowledged leaders of the craft must be careful where they tread, because, considered from a scientific, artistic, or business point of view, it is a mightily cantankerous

subject is this same photography. How much more, therefore, must the new recruit walk warily? Common sense, diligence, consideration for other people (even including the poor old boss), punctuality, are as valuable assets to the young photographer as they are to anyone else who wants to get on solidly.

There is no need to go to the other extreme if one is blessed with a little extra gumption. I remember when I was young I could never be cajoled into photographing anyone or anything out of business hours. Photography was my paid job, and there it began and ended. This was silly, and later on I saw the mistake, and began to take a secondary interest in other lines of photography, but this I kept strictly separate from my job. It is quite possible to study photo-micrography, say, at home, and some day it may be of very great use, and if a youth cares to confide in his employer—but not when the latter is up to his neck in work or worry—it is always possible that he will experience the other's interest and goodwill.

So always try to give your best to the work you are paid for, and don't neglect it. Walk squarely before you run, run before you soar. Few are born into their own high-class studios, and some of those go smash. Many have got there by the slow process of deliberate self-advancement, however, and these are the class who have brains, and brains to use them rightly.—THERMIT.

Tidiness in Trimming the D. and P. Prints.

WHERE a very large number of small prints have to be trimmed, and particularly when the work is being done under rush conditions, the workroom is very liable to get into a most untidy state through the collection of the trimmings on the floor. As shown in fig. 1,

Fig. 1.

all this mess can be avoided by providing a wide slot in the working bench close to the place where the trimmer is used. The trimmings then collect in the drawer as shown in fig. 2. This latter figure

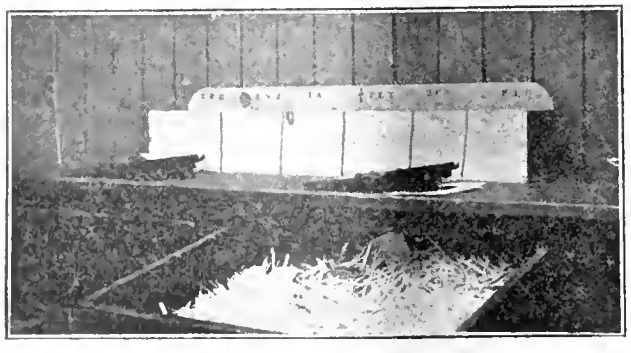

Fig. 2.

also shows another handy accessory for the trimming bench, namely, a box divided into a number of sections, each for prints of a particular size. By using the box prints are sorted out into their proper sizes as fast as they are trimmed, and much labour in subsequent sorting is thus saved.—L. HIRSTWOOD.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, July 17 to 22.

PRINTING-SURFACES.—No. 19,723. Appliances for production of printing-surfaces by photography. T. W. Brown, A. Orreli, and J. Robertson.

PRINTING FRAME.—No. 20,085. Photographic printing frame. W. J. Brown.

PRINTING.—Nos. 19,996, 19,997, 19,998, 19,999. Photographic printing. E. K. Hunter.

COLOUR PHOTOGRAPHY.—No. 20,070. Photo-colour process. M. Martinez.

CAMERA ATTACHMENTS.—No. 19,699. Devices for attaching photographic apparatus, etc., to base. F. N. Trier.

MOUNTS.—No. 20,148. Photographic mounts, albums, etc. J. Walker.

CINEMATOGRAPHY.—No. 19,918. Motion-picture projection apparatus. Pathé Cinéma Anciens Etablissements Pathé Frères.

CINEMATOGRAPHY.—No. 19,919. Electric lamps for cinematographic apparatus. Pathé Cinéma Anciens Etablissements Pathé Frères.

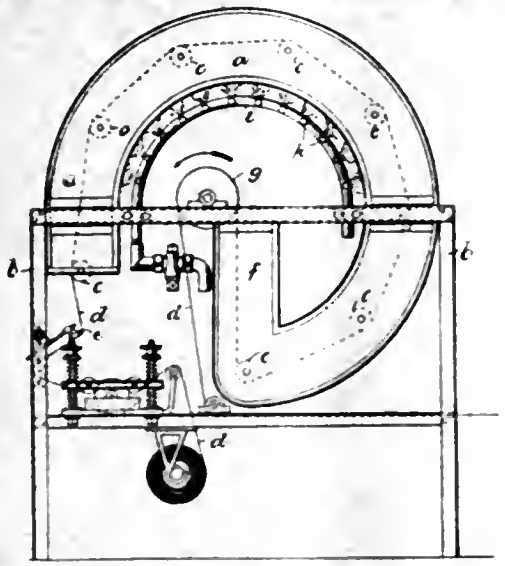
COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

COLOUR PRINTS FROM SCREEN-PLATE NEGATIVES.—No. 182,167 (March 21, 1921). The invention consists in the making of prints in colours on a paper or other opaque support from a screen-plate transparency in complementary colours, obtained in the usual way by development of the image to a negative without subsequent reversal. The essential in the invention is the use, for the screen-plate mosaic filter-film of mixtures of dyes, some of which, by treatment with acids or alkalies or by other chemical treatment, are rendered colourless, and some of which are originally colourless but become coloured by the above treatment.—Michael Obergassner, 31, Kaufinger Strasse, Munich. (Details of the process are given on another page in the "Colour Photography" Supplement.)

Drying Blue-Print Paper.—No. 179,832. (May 25, 1921). A drying-chamber for ferroprussiate and like photographic papers is of circular or polygonal form, and is so arranged that the treated side of the paper is not touched during its passage



through the chamber. The drying chamber *a* is supported by a frame *b* and rollers *c*, over which the paper *d* passes after it leaves the scraper *e* of the coating-apparatus. External heating-elements extend over the greater part of the chamber, but internal electric heating bulbs coloured or treated to avoid harmful actinic rays may be substituted.—John William Davies, 30, Rothschild Road, Chiswick, London, W.4.

Ferrotype Cameras.—No. 179,451 (June 8, 1921).—The casing *a* of the camera is of suitable rectangular shape. The front wall is provided with a hole in which is fixed a socket *b*, the inner end of which is provided with an inwardly extending flange b^1, to support the lens *c*, the latter being secured by a ring *d* forming a tight fit within the socket.

Mounted on the front of the camera is a metallic plate *e*, secured thereto by screws e^1. The vertical sides of this plate are formed by bending into U-shaped guides e^2 within which is slidably mounted a plate *f*, the upper edge of which is turned outwardly at f^1 to form a lug by means of which it may be raised within the guides. Suitable stops may be provided for limiting the movement of the shutter plate *f*, the arrangement

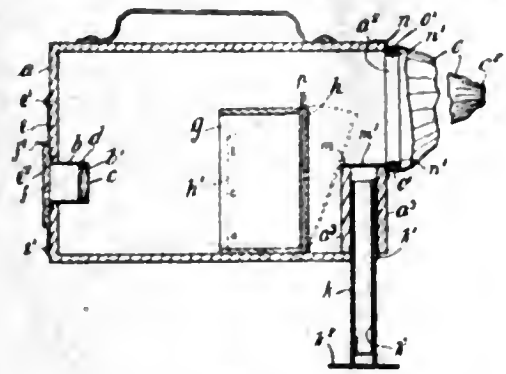


Fig. 1.

being such that the plate *f* is raised to its maximum extent to uncover the aperture e^3 (fig. 2) in the frame *e*.

Within the camera casing *a* is rigidly fixed a box-like frame *g* open at its front and rear, and embracing this frame is a holder *h* formed of sheet metal the sides h^1 of which extend forwardly and engage the outer walls of the frame *g*. The sides of the holder are preferably provided with projections h^2, whilst the sides are so shaped that they have to be sprung apart to place the same around the walls of the frame *g*.

The rear wall of the camera casing is open at a^2, whilst the lower portion of the rear wall is provided with a double wall a^4 within which is placed a tank or receptacle *k*. The tank *k* is of such size as to form a snug fit within the chamber walls a^3 and is provided on one side with a rib k^1 abutting against the bottom of the rear wall a^3 so as to limit the exent to which the same may be inserted. The bottom of the tank may have a base plate k^2 fixed thereto to enable the same to stand on a table or other surface, when removed from the camera.

Within the tank is loosely but slidably mounted a fork-like member k^3 the upper and lower ends of which are provided with U-shaped portions on opposite sides thereof. The lower U-shaped portion serves to support the plate or card placed

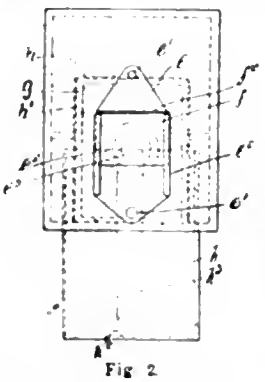

Fig. 2.

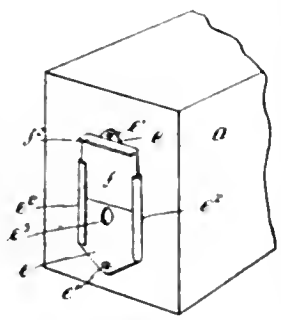

Fig. 3.

therein, and when the fork is raised the plate or card will be raised to a position to be easily removed.

The top of the rear wall a^3 is closed by a felt strip *m* provided with a longitudinal slit m^1 through which the plates or sensitive cards may be passed.

Surrounding the opening a^2 of the rear wall of the casing *a* is a flanged frame *n*, which is provided with a projecting channelled flange n^1 the concave side of which is turned outwardly. *o* is a sleeve of tubular form, formed of opaque fabric, the inner and outer ends of which are provided with a hem. The inner hem o^1 is adapted to receive a cord which, when the sleeve is placed in position with the hem around the channelled flange n^1, permits the sleeve to be secured to the frame in a light-tight manner. The hem o^2 at the outer end of the sleeve is preferably provided with an elastic cord or the like which normally partially closes that end of the sleeve. When the opaque sleeve is thus secured in position, the hand of the operator may be inserted into the outer end and by passing the hand through the sleeve the plates or cards may be placed in position or removed from the holder and passed through the slit in the felt strip *m*.

The strip *m* is normally sufficient to prevent light entering the casing *a* when the tank is removed, and when the plate is to be placed in position the top of the holder *h* is pulled back, causing the same to pivot about the bottom of the rear-portion hereof which rests on the bottom of the camera, the inner surface of the hollow wall a^3 limiting the rearward movement thereof as shown in dotted lines in fig. 1. The cards or plates *p*, are placed in position against the inclined inner face of the holder which is

Fig. 4.

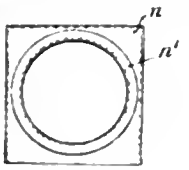

Fig. 5.

then pressed forwardly to the position shown in full lines. After the photograph has been taken, the hand is again inserted through sleeve *o* and after pulling back the top of the holder *h*, the front card (if more than one are carried by the holder) is removed and inserted through the slit m^1 into the tank *k* which has previously been supplied with combined developing and fixing solution.

The hand may now be withdrawn from the sleeve *o* and the latter is pushed into the opening at the rear of the camera. The tank *k* is retained in position within the hollow walls of the casing for a sufficient time to enable the developing and fixing of the plate or card to be effected, and when this operation is completed,

the tank is withdrawn, and by raising the fork k^3 the plate or film may be removed. Before the withdrawal of the tank takes place the opaque sleeve o is preferably pushed into the body of the camera to prevent any possibility of the light entering the camera through the slit m^1.—Edmond Francis Stratton, 1, Cedar Street, South Norwalk, Connecticut, U.S.

The following complete specifications are open to public inspection before acceptance :—

COPYING.—No. 183, 124. Device for copying the surface to be obtained from a photo-stereogram of a spatial form. Firm of C. Zeiss.

TELEGRAPHIC TRANSMISSION.—No. 183,135. Transmission of photographic images by means of the usual telegraphic, telephonic and radio-telegraphic apparatus. U. and P. Ellero.

New Apparatus.

Pentac f 2.9 Anastigmat Portrait Lenses. Made by J. H. Dallmeyer, Ltd., 11d, Regent Street, London, S.W.1.

THIS series of lenses has been introduced with the object of providing the portrait photographer with objectives of larger aperture than has hitherto been available in any type of lens. While small lenses, particularly those for cinematograph cameras, have been made, notably by Messrs. Dallmeyer, of considerably larger aperture than f/2.9, they have been of quite short focal length. In the present series focal lengths of 6, 8, 10 and 12 inches are available, representing a much more difficult optical problem. It may be questioned whether there is a considerable proportion of studio subjects for which so large an aperture as even f/3 can be employed, for very frequently a smaller stop must necessarily be used in order to secure sufficient definition in planes at different distances from the camera. Yet subjects do frequently arise for which the portrait photographer badly needs all the rapidity which he can obtain from his lens, and from that standpoint the new Pentac anastigmat represents, so to speak, a reserve of power which can often be advantageously drawn upon.

As the result of examining the lens which has been sent to us, namely, one of 8 inches focal length, we find that it covers satisfactorily the plate for which it is listed, namely, the 5 x 4. The 6-inch lens is made for quarter-plate; the 10-inch for half-plate; and the 12-inch for 7 x 5 inches. The prices are as follows :—6-inch, £18; 8-inch, £24; 10-inch, £32; and 12-inch, £40. For an additional cost of £2 10s. the lens may be obtained in a mount providing for a certain degree of diffusion of focus. The new objective represents a further power in the hands of the studio portraitist, and will undoubtedly find its application both by those who require to cut down exposures in daylight studios to the shortest possible time when dealing with such subjects as young children, and also by others who may be compelled to use gas or other artificial illumination with which the employment of an ultra-rapid lens is a sine qua non in reducing exposure to a time which is readily obtainable with other systems of artificial illumination.

CROYDON CAMERA CLUB.

Mr. W. C. Price gave a lecture on "The Formation of the Fine Art Trade Guild," an important association within the sphere of its operations, but unheard of by many members.

The Guild was founded in 1910, and comprises fine art publishers, painter-etchers, and others, and retailers. It was preceded by the Printsellers' Association, a body which did useful work, but lacked sufficient authority to enforce its decrees, and eventually it became absorbed by the guild.

It swept away many abuses which had crept into the trade, and by strength of membership was soon able to make binding laws, and inflict penalties for disobedience to them. On one occasion, Mr. Price said, a celebrated West-End firm flatly defied the Guild and was immediately expelled. In less than a fortnight, forced by necessity, an abject appeal was made for pardon and reinstatement. The firm was penalised by three months' isolation, and then re-admitted.

The main functions of the Guild are to uphold the dignity of the trade and protect the public from fraud of any description. Purity of medium is insisted upon, and woe to the publisher who gives, say, a mezzotint a little reinforcement with aquatint. The Guild will, therefore, not appeal to the photographic pictorialist of the medium-mixer type.

It safeguards the purchaser as to the number of proofs issued, limits their number, inspects and passes each proof, and stamps it. On the left-hand in earlier proofs; on the right in later. After "Letter-proofs," subsequent prints (in the eye of the Guild) are considered of no value, and are not stamped, but when the issue is completed the plate is destroyed. In old days many a time has a much worn plate been sent to the Continent to be refaced with steel, and inferior prints pulled from it, and imported in thousands, much to the detriment of the original purchasers.

The Guild has now many branches, and has turned its attention to the art education of assistants engaged in the trade. Lectures are given by prominent men, and a library is in course of formation. A most hearty vote of thanks was accorded Mr. Price for a lucid sketch of an interesting and powerful corporation.

Prior to the close of the evening the secretary, Mr. J. M. Sellors, announced he was going on a holiday, and was, therefore, forced to hand over control to the "office boy." He hoped for the best, and feared the worst. Several informal fixtures had been arranged. The member just alluded to would give an evening on "Manners and Deportment in the Saloon Bar," Mr. Vivian Jobling acting as barmaid. Mr. Harpur would expound on "Modesty," and the President on "Silence." This intimation considerably astonished those principally concerned.

A NEW STYLE OF SKETCH PORTRAIT.—The Sketch Portrait Co., of 18, Doughty Street, London, W.C.1, send us a specimen of a new style of sketch portrait which they are introducing in a very neat pattern of passe-partout framing. The portraits range in size from 10 x 6 inches to 19 x 14 inches, and are supplied at prices from 8s. 6d. to 30s. each. The specimen before us of 17 x 12 size is a remarkably effective piece of work in black and white, in which full use is made of cross-hatching both in the background and in parts of the figure, with the result that the portrait has very largely the effect of a pencil sketch, the photographic tones contributing, as it were, the fine shading which a draughtsman would produce with his pencil. The portraits are also executed in a similar style in sepia and water-colour, and we are quite sure that the freshness and novelty which they exhibit will recommend them to photographers seeking something different, yet of distinction, for their show window. The Sketch Portrait Co. is making a special offer to supply a set of three of these portraits from a photographer's negatives, one in water-colour, one in sepia and one in black-and-white, each of 17 x 12 inches size, carriage paid for 35s., and it is an offer which may advantageously be accepted.

Commercial & Legal Intelligence.

LEGAL NOTICES.—Notice is given that a general meeting of the members of the London Photographic Co., Ltd., will be held at 48, Langler Road, Willesden, N.W.10, on August 23, at 8 o'clock, for the purpose of considering the liquidator's report, showing how the winding-up of the company has been conducted, and its property disposed of.

Notice of intended dividend has been given in the case of James Alfred Derbyshire, artist, photographer, etc., residing at 1, Joddrell Street, Newtown, New Mills, and carrying on business at Goyt Studio, New Mills. Proofs must be lodged on or before August 8, with Archibald Yearsley, 27, Brazennose Street, Manchester, the trustee.

NEW COMPANIES.

ANGLO-FRENCH FILMS, LTD.—Registered July 21. Capital, £1,000 in £1 shares. Objects, to carry on the business of producers, manufacturers and exploiters of, agents for, and dealers in cinematograph films, phonographic records, cinematographic and photographic and kindred machinery, etc. The subscribers (each with one share) are:—G. E. Binsted, 168, Putney Bridge Road, Putney, S.W.15, solicitor's clerk; E. W. Howard, 8, Rye Hill Park, Peckham Rye, S.E.15. Registered office: 317, High Holborn, W. C.1. Private company.

News and Notes.

THE DERBY PHOTOGRAPHIC SOCIETY, which has been derelict since 1915, has been revived, and Mr. T. A. Scotton, of 179, Osmaston Road, Derby, has been appointed hon. secretary.

THE REFEREE, in its issue of Sunday last, exhibited the interest of its manager, Mr. H. C. Pharaoh, in photography, by publishing a special photographic article, by Mr. P. R. Salmon, on holiday photography. It is intended to make photographic notes a more or less regular feature of this popular Sunday newspaper.

LETO PHOTO MATERIALS CO., LTD.—It is announced by Messrs. Wellington & Ward, Ltd., that they have acquired the business of the Leto Company. The manufacture of Seltona will be carried on exactly as hitherto, but all communications, orders, etc., should be addressed to the firm of Messrs. Wellington & Ward Ltd., Elstree, Herts.

MESSRS. JOHNSON & SONS, Manufacturing Chemists, Ltd., of 23, Cross Street, Finsbury, E.C.2, have received a postcard with a Bristol postmark bearing an inquiry from a professional photographer or a photographic dealer, regarding tank developer for a 5-gallon tank. Unfortunately the card is without name or address, and Messrs. Johnson & Sons think that as the writer of the card is probably a reader of the "B. J.," he will see this paragraph and be able to disclose his identity.

MR. ARTHUR WARMISHAM, M.Sc., has been elected a director of Taylor, Taylor & Hobson, Ltd. Mr. Warmisham, during the years in which he has been with the Leicester optical firm, has introduced a number of important inventions. Among these are the well-known Taylor-Hobson Cooke Aviar lenses, which achieved so much success during the war for aerial photography. Mr. Warmisham also succeeded in producing a cinema projection lens, which is rapidly taking its place in the cinema trade on account of the much greater amount of light transmitted to the screen.

CAMERA.—Under this title an illustrated monthly magazine has begun publication in Lucerne, where it is issued by Messrs. C. J. Bucher. The new publication, which is in the German language, makes a strong feature of pictorial photography, and includes an 8-page art supplement of reproductions of the pictorial work of C. Kosel, of Vienna. Nevertheless, there are a number of technical articles, including one by Dr. E. Konig on his new desensitisers, and another by Dr. Lüppo-Cramer on the grain of plates. "Camera" is published at the price of 1.50 francs per issue, or 16 francs per annum.

ENGINEERING PHOTOGRAPHS.—At their private cinema theatre in Broadway, Westminster, Messrs. Vickers last Friday gave a private view of a series of films which are to be sent to the Brazilian Centenary Exhibition at Rio de Janeiro. These films, which have all been made by the firm's own photographic department, are in seven sections, and are selected to form a judicious blend of the technical and the popular. Two of them illustrate the processes of making steel at the River Don works at Sheffield and the manufacture of files, springs, magneta, guns and other articles: in another the firing trials of the guns are to be seen; another shows shipbuilding and marine engineering operations at the Naval Construction Works, Barrow; and two are concerned solely with aeronautics.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—Members are reminded that any proposed resolution for the adjourned general meeting, to be held on September 15, must be sent to the secretary six weeks before the meeting, in accordance with Article 20, viz.: 20. Any member entitled to be present and vote at a meeting may submit any resolution to any General Meeting, provided that at least the prescribed time before the day appointed for the meeting he shall have served upon the Association a notice in writing signed by him containing the proposed resolution, and stating his intention to submit the same. The prescribed time above mentioned shall be such that between the date on which the notice is served or deemed to be served and the day appointed for the meeting, there shall be not less than six weeks. Also, according to Article 12. "Every member may nominate any one member for election to the office of President and any other member to the office of treasurer, and every member may nominate four London and four country members for election to the Council. The nomination papers must be sent to the Secretary at least fourteen days before the annual general meeting, together with the written consent of the members nominated to serve if elected."

Correspondence.

*** *We do not undertake responsibility for the opinions expressed by our correspondents.*

CONTINENTAL NEGATIVE VARNISH.

To the Editors.

Gentlemen,—In the interesting letter dealing with the preservation of negatives (published on page 454 of last week's "B.J.") the writer, Mr. E. D. Shortt, speaks highly of a benzene-like varnish used by a Continental firm of view publishers for their negatives, and says that he has been unable to ascertain the formula for the varnish.

I, too, used a benzene-like varnish when employed in a Continental house, but it was by no means a simple and easily made varnish; indeed, we gave it up because of the difficulty of mixing and the too many constituents. However, as your correspondent seems to desire to renew his acquaintance with a benzene mixture I will give him the formula for the varnish we used. It was one my fellow workers and myself did not care for, though it had been used by the firm for a generation or more.

The benzene varnish is a cold one, and the formula stands as follows:—Benzene, 3½ oz.; acetone, 3½ oz.; absolute alcohol, 1½ oz.; sandarac, 300 grs. Mix the solvents, warm slightly on a water bath, and dissolve the sandarac while the combined solution is warm; filter, bottle and keep tightly corked when not in use. Although this contains as much acetone as benzene, it was known to us as a benzene varnish.

Mr. Shortt uses the word "benzine," but this, I should say, is a slip of the pen, and that benzene was intended. Benzine is, I believe, practically identical with petrol, which is rarely, if ever, used for varnishes, whereas benzene (or benzole) is a recognised constitutent of varnishes. A crystal of iodine dropped into benzene turns carmine coloured whilst with benzine a violet colour is obtained. And further, a drop or two of absolute alcohol will not mix with benzine but mixes at once with benzene.—Yours truly,

E. W. H. TAYLOR.

Liverpool.

To the Editors.

Gentlemen,—The "benzine" negative varnish your correspondent thinks so highly of is probably nothing more than the old-fashioned benzole gold size varnish (equal parts of each), which

has been known to old hands for generstions, and is still used by many of them, in spite of the introduction of newer snd improved varnishes for dry-plate work.

A mixture of equal parts of good commercial gold size and benzole (which is benzene and not benzine or benzilene) is one of the best of cold varnishes, in spite of its simplicity. Gold size, it may be said, is really a solution of copal or amber (resins) in boiled linseed oil thinned down with the best turpentine. It is met with in many degrees of purity, from the rather common oilshop variety to the best "copal varnish" supplied for artists of the brush. The varnish takes about half an hour to dry properly, but it appears to be the one your correspondent requires.—Yours faithfully,

E. A. Stokes.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

G.L.A.—We have never heard of the Rutherford engine in the connection you mention, or in fact in any connection, and after making inquiries among process people, who might be expected to know, cannot hear anything of it. If it was a patented engine, you could easily look up the name of the patentee in the annual indexes in the Patent Office Library, 25, Southampton Buildings, Chancery Lane, W.C.2.

G. W.—The average strength of solution of potass bichromate for rendering gelatine sensitive to light is from 5 per cent. to 6 per cent. We have not our previous letter at hand, but we hope we represented to you that it is by no means an easy matter to obtain substantial relief by printing on a bichromated gelatine film. We do not think that there is very much prospect of your getting results which will satisfy you.

R. H.—Local authorities make their own regulations in regard to the practice of outdoor portraiture in streets and on beaches. In most places the Town Council, or other authority, sells the rights to photograph on the beach, and, therefore, prohibits photography by anyone except the concessionaire. As regards other places, police authorities sometimes require the photographer to have a hawker's licence in order to canvass from door to door or to take portraits of passers-by. You had better apply to the chief police office in your town.

A. F.—Most lenses of this double anastigmat type cover, at the full aperture, a larger plate than that for which they are listed, and a still larger one if stopped down. Generally speaking, the lenses which give this facility are those which have not a maximum aperture larger than about *f*/7, it being possible, in a lens of this type, to provide for corrections and covering power over a wider angle than can be done when the construction is directed towards obtaining a large maximum aperture, such as *f*/4.5. We suppose that this is the information which you require.

O. D. B.—Under the circumstances you name we are of opinion that you would do well to keep to the incandescent gas, using the burner marked A on your list, and either the E or G plates. The allegation referred to has been officially denied since you penned your letter. It is stated that the amounts are checked four times before the bills are tendered, and if the public choose they can check the figures themselves. The meter card shows the number of feet consumed, and the scale on the back of the card or gas bill shows how to reduce to therms. The sum is easy. Multiply the number of feet registered by the calorific value of the gas supplied (in your case 500) and then divide by 100,000.

J. J.—For the best rendering of the inlaid mahogany work a panchromatic plate is necessary. You may choose any of the panchromatic plates on the market, and might well use a K2 or K3 screen. You will find there is an enormous improvement in the rendering of the woods and also of the grain of each one by this combination. The little book, "Commercial Photography," which we issue, contains a lot of information, but the best treatise on the subject is "The Commercial Photographer," by L. G. Rose, an American book published by F. V. Chambers, 636, Franklin Square, Philadelphia, Pa., U.S.A., price 4 dollars. So far as we know, it is not on sale in this country.

D. B.—The formula for the retouching medium you refer to is:—

Pale gum resin	200 grs.	230 gms.
Gum dammar	90 grs.	100 gms.
Gum mastic	20 grs.	23 gms.
Oil of juniper	1 gr.	1 gm.
Oil of turpentine	2-4 ozs.	1,000-2,000 c.c.s.

The gums are powdered and added to the oils, and finally enough pure asphaltum is added to give the mixture a dark amber colour when viewed through the depth of an inch. This formula is strongly recommended by Whiting in his "Retouching" as not liable to pick, rub off, or come off on after-varnishing. It takes a great deal of work.

W. F. G.—The formula for copper toning is:—

A.—Copper sulphate	60 grs.	7 gms.
Potass. citrate (neutral)	240 grs.	28 gms.
Water	20 ozs.	1,000 c.c.s.
B.—Potass. ferricyanide	50 grs.	6 gms.
Potass. citrate (neutral)	50 grs.	28 gms.
Water	20 ozs.	1,000 c.c.s.

Use equal parts of each. If prints are pinkish in the high-lights, use more citrate in the A or B solution. This process yields a range of tones from warm black to red chalk on bromide prints, the warmth of tone increasing as the solution acts on the print. The process does not intensify the prints; it is cheap and the results are permanent.

A. C.—It would be a rather long story to answer your question on depth of focus, and, perhaps, it will be satisfactory to you to wait for the appearance of a series of chapters on the subject which we have in type, and which should appear within the next few weeks. From one point of view depth of focus is independent of the focal length of the lens, and depends only on the actual diameter of the lens stop, but that basis does not serve invariably owing to the fact of the limited accommodation of the eye, which makes it necessary for the print taken with a lens of such short focus as 3 inches to be viewed at about the same distance (10 inches) as one taken with a lens of three times the focal length. This property of the eye upsets the doctrine according to which depth depends only on the lens aperture when the circumstances are such that prints from very small negatives are viewed without enlargement. We hope that the articles which are to appear will make clear many of the points which are somewhat obscure in the consideration of depth of focus.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3249. Vol. LXIX. FRIDAY, AUGUST 11, 1922. Price Fourpence.

Contents.

SUMMARY.

In a leading article we refer to a few of the pitfalls into which assistants often fall in applying for situations which they see advertised, and at the same time draw attention to the means they should take in collaboration with our publishers to avoid loss of specimens of their work. (P. 470.)

In a further paper on studio work, Mr. J. Effel deals in a novel manner with the point of view in portraiture, condemning the "full front face," and advocating more artistic treatment. (P. 471.)

One or two of the precautions which require to be observed in the use of toning with "liver of sulphur" are the subject of a paragraph on page 469.

Two simple ways of determining the correction of lenses for chemical focus are described on page 475. It is shown how, when the correction has been found for a particular lens under one set of conditions, the correction under every other condition can be calculated.

In a paragraph on page 469 we explain to what degree it is possible to form an opinion as to whether the copyright in an old photograph has ceased to exist.

Three new sensitisers for the deep red, which have been selected as having interesting properties, are dealt with in a communication from the Eastman Kodak Company's Research Laboratory. Two of the dues—Naphthacyanole and Kryptocyanine—are being placed on the market. (P. 474.)

A hint on economising plates—using sometimes a 15 × 12 cut in halves for long, narrow groups—is given on page 470.

In the use of a camera for copying, a great deal of time and labour may be saved by the provision of a scale, serving to set the camera extension according to the scale upon which an original is to be reproduced. (P. 470.)

In the present issue appears the first of a series of chapters on an old subject in photographic optics, viz., depth of focus. Despite all that has been written, there still exists, we think, some confusion between the two views which have been taken of depth, and therefore it may be useful to explore the first principles of the subject, as is done in the present chapter, and then to show how and why in some circumstances depth may be regarded as dependent only on the actual aperture of the lens stop whilst in other circumstances the focal length of the lens may also be taken into account. (P. 476.)

Where a number of prints are required, and particularly if a suitable artificial light is available, the running off of a batch of print-out prints is practically as expeditiously done as when using development papers. (P. 470.)

The Edinburgh Society of Professional Photographers have decided not to hold the proposed Fair in March next, but are considering whether a Congress and exhibition cannot be held in place of it. (P. 481.)

Customs duties when taking a foreign-made camera to the Continent are explained in a note on page 482.

EX CATHEDRA.

Single Solution Toning. While the tone which can be obtained upon various brands of bromide paper does not vary greatly when properly developed prints are bleached and sulphided in the usual way, a warm sepia being usually obtained, this is not the case when a single solution, such as hypo-alum or liver of sulphur, is employed. With some papers nothing beyond a cool purple, resembling that of a chloride print toned in the usual gold and sulphocyanide bath can be obtained, while others will tone readily to quite a warm or even a yellowish sepia. It is therefore very necessary, when experimenting with "liver" toning, to obtain several samples of paper, so that a suitable one can be chosen. Probably the greatest advantage of the single solution toning is that the process can be arrested at any desired stage from a warm black to a sepia. It should be noted that the rapidity of action and, to a certain extent, the colour is largely dependent upon the temperature of the solution. Some papers also tone much more quickly than others, a tepid solution acting in a reasonable time. In such cases any preliminary hardening becomes unnecessary.

* * *

Has Copyright Expired? The question of the existence of copyright in a photograph of obviously ancient date is one which now and again presents itself to photographers, for example, when an old portrait is brought in to be copied. While it is not always possible to say definitely, from such particulars as a customer may supply, whether copyright has or has not expired, a knowledge of the retrospective effect of the present Act upon the term of copyright created under the previous Act of 1862 will do something towards justifying a fairly reasonable conclusion. It needs to be remembered that, in respect to all works in which copyright subsisted when the present Act came into force on July 1, 1912, the effect of the latter Act is to assign to them a term of copyright of fifty years from the making of the negative. In this respect, therefore, the present Act is a great improvement on the former one, according to which copyright lasted for the life of the owner and seven years after his death. Under the old Act, it was indeed more difficult to ascertain the existence of an old copyright than appears on the surface, since the Courts held that the "author" was the actual person who arranged and took the photographs. Thus, the "author" might be, and often was, an assistant of the photographer whose name appears on the mount. Therefore, from these considerations, the first thing to do in seeking to arrive at an opinion as to whether there is copyright in a photographic portrait is to answer the question: Is it likely that the actual taker of the portrait was alive on July 1, 1905, that is, seven years before the present Act came into force? If it appears improbable that he could have been, then the inference is that copyright had expired

before July 1, 1912. If, on the other hand, it is conceivable that the "author" was alive on July 1, 1905, the existence or non-existence of copyright turns solely on the number of years which have elapsed since the making of the negative. If less than fifty, the copyright is still in existence; if more than fifty, it has expired. In the case of most photographs taken, say, thirty or forty years ago, any decision is little more than a guess.

* * *

Economising Plates. While the present price of plates continues, there is every necessity to avoid exposing the larger sizes wastefully. In many cases this can be done by cutting two plates from the next larger size, which, in the case of many subjects, give the necessary area. Many groups, especially flashlights of dinners, call for a long, narrow plate, a fact which our American friends have recognised by providing cameras to suit. Very often a plate 12 x 7½, or sometimes 15 x 6, will suit the subject; either of these sizes may be made by a single cut from a 15 x 12 plate. There is little difficulty in using these in the ordinary slides, all that is necessary being two strips of glass, one on either side of the plate, to keep it central. To obviate the risk of slipping, a strip of adhesive plaster or insulating tape may be rubbed down along the edges, or even a slip of lantern binding stuck on. If such sizes are taken into general use, a simple grooved carrier may be made, into which the plate may be slipped. With such an arrangement, flat films which are more easily cut can be utilised.

* * *

Printing Out. It has come to our notice that some of the younger generation of photographers, whose experience dates from a time subsequent to the general adoption of developing papers, have been deterred from using any printing-out process by the idea that a great loss of time is involved by so doing. This is undoubtedly the case if only a few negatives have to be dealt with, but if, say, two or three dozen can be handled simultaneously the difference is not serious. In the case of sepia prints, in which, besides developing, bleaching and sulphiding have to be resorted to, there is probably no saving in time as compared with a self-toning collodion paper, while the results are, as a rule, much better. There is, of course, always the uncertainty of the quality of daylight, but if a mercury vapour tube be used, printing-out becomes an easy task, whether self-toning, carbon or platinum paper be used. It is necessary to point out that unless used by reflection, which is expensive, the arc light does not give satisfactory prints, there being a tendency to general flatness. Half-watt lamps have been found altogether too slow for printing purposes.

* * *

A Scale for the Copying Camera. An accessory for the camera with which much copying is done may be made in a few minutes and will be found to save a great deal of time in adjusting the camera extension into position for approximately sharp focus. Assuming that the camera is, as it should be, one of the rear-focussing type, let a strip of wood of length a little more than twice the focal length of the lens, be fixed to the lens-front by one end, the rear end thus projecting beyond the camera back at about the normal extension. Let the camera be focussed on a distant object and a mark made on the wooden strip registering with some definite part of the camera back, such as the front edge of the frame. Let this mark on the strip be called A. Now let some piece of printed matter be sharply focussed, so that it is reproduced same size on the focussing screen, and let a second mark B be made on the strip of wood. It now only remains to divide the space between A and B into, say, sixteen equal parts, and to mark these divisions, 1-16th, 1-8th, 3-16th, etc., on the strip, starting from the point A, in order to obtain a scale which, for the particular lens, indicates the position to which the camera requires to be extended for sharp focus when copying on any of the scales marked, as described above, on the graduated strip. Thus, for reproduction of a 12-inch original as 9 inches in the copy, that is on a scale of three-quarters, the camera back is racked to the three-quarter mark and focus obtained by moving the instrument as a whole nearer to or further from the original.

"IN REPLY TO YOUR ADVERTISEMENT."

In consequence of the considerable number of small advertisements by employers requiring assistants and by assistants requiring employment, which appear week by week in our advertisement pages, we are often called upon to deal with debatable matters arising from those advertisements, and incidentally have frequently the opportunity of seeing the letters which are written to an employer by applicants for a situation. We may, therefore, be rendering some service to assistants if we bring together a few notes, the result of our observations in these affairs.

One of the first things we would do is to caution assistants against sending to employer advertisers who use a Box number specimens of their work or originals of their testimonials. In the past, to our certain knowledge, the readiness of assistants to send specimens of their work to unknown people has been much abused; so much so, that for a number of years past our publishers have declined to insert requests for specimens in advertisements of situations vacant which do not disclose the name and address of the advertiser. Nevertheless, despite the absence of the request, assistants do send their specimens and, therefore, have only themselves to blame if they are unsuccessful in getting them again. There is, of course, no reason to attach suspicion to an advertiser because he employs a Box number. He may have the best of reasons for not wishing to disclose his identity. On the other hand, the use of a Box number is a means which may be used by the unscrupulous for obtaining specimens for the window or showcase. There is a further cause of failure on the part of assistants to obtain recovery of their specimens, and that is one which is scarcely to be ascribed to the evil intentions of the advertiser. It is, that an assistant will omit to mark his name and address on the back of each specimen. He may send half-a-dozen such unmarked specimens with his letter of application, presumably under the happy impression that he is the only applicant. The advertiser, who perhaps has thirty or forty similar letters and batches of specimens in response to his announcement, can hardly be wholly blamed if, in such circumstances, specimens get mixed up, so that they cannot be returned to their proper owners. Another hint about specimens which we may give to assistants is that the prints should be nicely mounted. Many of the specimens which we have seen have been frayed and dirty prints, the state of which greatly detracted from work which, so far as the capacity of the assistant in the studio was concerned, was quite creditable.

As regards the letters which are written in reply to advertisements, let them be of the utmost conciseness, consistent with statement of the required facts. No need to begin with "In reply to your advertisement for a receptionist in Friday's 'British Journal,' I beg to

offer my services." The employer knows all that, and gets tired of reading it as the introduction of thirty or forty letters. Hence he is biassed, to some extent, in favour of the applicant who cuts it out. We are rather inclined to think that the best way of putting one's qualifications before an employer is to write a brief note simply stating the salary required and date when at liberty. Other particulars may be concisely given on a separate sheet, taking care to mark this latter with the name and address of the applicant. It is just as well to make these particulars into separate short paragraphs, each dealing with a separate qualification, *e.g.*, experience in different branches of work, names and addresses of past employers with dates of entry and leaving service. Particulars of the latter kind may with advantage be drawn up in a kind of diary form, showing how and by whom the applicant has been employed in a course of years. Such particulars as these, where the terms of service have been of reasonable length, are evidence of reliability, to which, of course, an employer will attach as much importance as technical efficiency. If assistants who find a difficulty time after time in obtaining even an answer from an employer's advertisement could compare the neatly written and plainly expressed letters of others with their own rambling and almost illegible applications they would obtain some idea of the cause of their ill success.

A few words may be said respecting assistants' advertisements for situations. These, to begin with, should define the special branch of work as definitely as possible, *e.g.*, printer, operator, retoucher. They should also give at least some idea of the geographical position of the assistant. We can well understand that for obvious reasons an assistant often will not wish to name the town in which he or she is situated, but the county or the distance from some large town might be stated, so that an advertiser has some idea of the facility or otherwise with which he can interview an assistant beforehand. Assistants also may at times turn to advantage the fact of being out of employment by offering to take a berth at a minute's notice in response to a letter or telegram. Just now, in the height of the holiday season, there is, no doubt, an opportunity for making a feature of such readiness in advertising for a post.

WITH A PORTRAITIST IN THE STUDIO.

[The following is a further paper of the series by Mr. J. Effel, written with the aim of giving a more intimate kind of instruction in the practice of studio lighting and posing than is perhaps ordinarily attempted in articles of this kind. The two previous papers appeared in the "British Journal" of last week, the first being an introduction to the series and the second dealing with the arrangement of the bust portrait. Further chapters in the series will be published during the next few weeks.]

III.—THE POINT OF VIEW.

If there is one thing more than another that stamps the work of the portraitist as commonplace and uninteresting it is the "full front face" picture. The man who offers the majority of his clients this class of goods has no right to grumble at bad business. To be quite charitable, however, it must be admitted that most of this "looking to the front" photography is produced in the belief that the public prefer those pictures to more ambitious efforts, and not a little because the photographer has not trained his eye to see anything but the obvious.

"Well, but what's wrong with the front face, and isn't it a fact that they ask for that sort of thing?" I hear someone say. Now, it is just to clear up this confusion that I am writing this chapter. Do not lose sight of the fact that I am more concerned with the consideration of the making of *portraits that will sell better* than I am about what might be described as "Photography for High-brows." I am an old studio worker, I have travelled widely and seen most phases of the business. I have intimate knowledge of dealing with the best people, and know how to cater for less intelligent patrons without loss of dignity. You will not find me talking of guineas to the man whose studio is in a purely working-class district and who simply *must* deal in postcards and conduct his business to suit the spending conventions of the wage-earning community. One need not offer red chalk carbons to a glossy bromide public. I do not think sufficient thought has been given to the small man by the leaders in the profession. We all admit that it is very much easier to photograph well-bred, well-dressed persons and children who will respond to our advances, taking reasonable time to the work, than it is to deal with those who, in addition to their awkwardness, are very frequently unable to appreciate beautiful and artistic work. After all, the West End man knows all I have got to teach and has everything in his favour. It is the worker in the middle class or cheaper studios that I am most concerned about "gingering up." Let me say this by way of comfort to the professional whose studio is an unpretentious one in an outlying suburb: there is no other business I know of where the small man can successfully compete with elaborate and central premises so much as in photography. One cannot imagine a lady forsaking the big store for the little draper round the corner, but for something distinctive and personal, such as a photograph, clients who have discrimination will go anywhere.

Probably you are wondering what the foregoing paragraph has to do with the iniquity of photographing sitters looking to the camera, so I'll be more direct and answer your questions. The human face is not a flat surface. I have compared it to a physical geography map. A photograph of the face is a representation on a flat surface of a more or less round object *as seen in monochrome with one eye*. If one could see a perfect face both eyes would be of the same size and shape, one ear would match the other, the nose would be straight and the mouth would not droop at one corner. Now, I think a face like that might be worth taking "full front" to show the regularity of the features, but, considering the limitations of the photographic lens, the nose, the face's most prominent feature, would not be truthfully rendered, unless by very skilful lighting. Assume, however, that we have got a good front face photograph of a perfect face. You will find that if a line were drawn down the centre of the picture, both sides would be exactly alike. Why then, I ask, should we photograph two ears and two eyes from exactly the one point of view, why should we foreshorten a good nose and chin, give but the one line of cheek and neck, and fail to indicate in the slightest degree the shapeliness of the head? There is no answer, unless you tell me that the public ask for photographs "looking straight at the camera." I have had that request nearly every week of my professional life, and, as a picture "that just looks at you" is very popular, I must explain how I reconcile my detestation of the front face with my ideas of giving clients what they like.

Customers only know what they want approximately. They use the terms "side," "front" and "full" to convey their meaning in a general sort of way. The photographer who

could argue with his sitter about the difference between "three-quarter face" and "full face," or, indeed, about any other technicality, would be an ass. When a lady tells me that she doesn't wish to be taken "too near the camera," I do not give her a lecture on the relativity of the focal length of the lens and the dimension of the sensitive plate. I know quite well that what she wants is a comparatively small figure. Not one person in a million would ask for a front face and then grumble if the head were turned slightly, and yet *that slight turn makes a world of difference*.

Let us turn back to the perfect face and the front view portrait of it. I showed that one side is but a repetition of the other and indicated that many beauties were completely hidden. Once, when out walking with my little daughter, I said, "Look over there at the pretty pond with the ducks swimming about." Margaret looked in the direction indicated, but saw neither pond nor ducks. Only when I put my head down to the level of hers did I notice that a small hillock completely hid what I wished her to see. A photograph from the child's standpoint would have shown us the landscape lacking in the interest I got from my slightly elevated position. Exactly so it is with a portrait. If the pond and the ducks

An unusual point of view disclosing a variety of "points"—the good profile, abundant hair, the beautiful curves of neck and arms. Note the simplicity of the scheme.

are worth disclosing, or, to drop the metaphor, if there are hidden beauties just round the corner, the camera or client should be altered to reveal them.

Always appear to gratify the wishes of your clients. If you leave a feeling that you have not taken a lady as she wished it is a certainty that your proofs will be severely criticised. Given a lady who has insisted on a front face, don't, for pity's sake, let her sit down facing the camera and then start turning her away. That will invite an argument right away. My procedure is as follows: "I 'size up" her better side and place the chair either slightly looking to the light or away from it, so that it is impossible for her to be "fair on" to the camera. Then, when the blinds have been arranged a little and my assistant has focussed roughly, I say "Now I must turn your head a little, for, of course, you wish to be taken looking at the front." It is then quite simple to select a pleasing point of view, and, the eyes always looking in advance of the turning, a "looking at you" portrait is perfectly easy. As a matter of fact, all the best portraits with the eyes looking to the front are what is known as "three-quarter" face pictures. Look at the portrait work of the old masters, look at the fine work of leading poster and advertisement artists, and, bearing in mind what I have said, I think you will be surprised at the wonderful variety possible with what would always satisfy the public as "looking to the front" portraiture.

Paradoxical as it may seem, a simple front face portrait calls for more knowledge than a "Rembrandt." It only requires the ability to focus and expose to make a photograph which will look like a schoolboy peering into a sweet-shop window. Something more is required by the public from the photographer who calls himself a "portrait specialist."

In practising selection aim to hide the ugly while showing the beautiful. Keep continually asking yourself, "What should I disclose here, what should I keep out of sight?" Our clients, as a rule, know nothing of Art and cannot give good reasons for their preferences and dislikes. It should be sufficient for us that they *don't* like our work. Nature punishes us for breaking her laws, but whether we have eaten unwisely, neglected our sleep, or carelessly exposed ourselves to cold, *we have to find out* to effect a cure and to guard against a recurrence of the trouble. Regarded superficially, there is but little difference between the front face portrait of an ignorant worker and that of an expert. Yet, put them to the vote of our ordinary customers, and the latter will win hands down. Why? Few will be able to satisfy us on that point beyond saying that there is "a something" about it that compels their preference. After all, it would be an evil day for us if the general public cultivated art criticism. Those who like beauty are far easier to serve than those who have a smattering of the technical side of our business. A well-known musician once put me right on the subject of the public. I had just told him that I was a music lover, but could play no instrument myself. "Then you are a lucky chap" was his unexpected remark, "for you can sit down comfortably and enjoy the art of a good performer—the soul of his music—while I can't help criticising his tone, tempo and technique. I always play to the music lovers, *never* to the musicians in my audiences. After all, old man, we are all members of the public on most subjects. Now, take your art, I'm just in exactly the same position regarding photography as you with music. I admire a picture—well, just because I *do* admire it, while you go nosing around it analysing and picking faults, because you are a confounded professional."

Don't take your portraits to satisfy photographers, but think very hard of pleasing your clients. If you are troubled with frequent re-sittings, or very small orders, it is up to you to find the reason, to find in what particular your work is lacking. Don't waste your breath reviling the public. Allowing for some annoying manifestations of right down stupidity—I have known a few masterpieces to be turned down—the fault is always with us, our work or its presentation. Take the rejected proofs, study them well, and then reconstruct them in your mind. Most likely the sitter told us what failed to please, or the fault may be quite apparent. Quite conceivably, however, you are at a loss to find out what is wrong. In such a case it is evident that the photographer is limited in his knowledge of the infinite variety and possibilities of his art. One who has seen little but front faces for years requires some extra knowledge, to say nothing of courage, to bring himself to look all round his subject for a pleasing point of view.

My reason for placing "the point of view" first in the factors that go to make up a successful portrait is that, like the skeleton to the anatomist, or the drawing to the painter, it is the structure upon which the complete composition is built, determining the general effect. "Yes, that's all very fine about selection," says a young studio assistant, "but now that you have ruled out the front face, what is to guide me and what rules have you for my guidance with all the different faces I have to deal with?" That is exactly the question I wish to answer.

We need not enter into an academic discussion on "What is Beauty?" for the Chinaman, the Kaffir and the Briton have different standards. Even with the white peoples there is considerable diversity of opinion, but it is sufficient for our purpose to mention those "points" about a face which we would all agree were good ones, to consider how to make the most of them in a photograph. A straight nose, large eyes, ears close to the head, regular teeth, abundant hair, rounded cheeks, lofty forehead, are universally admired. If ever you get that combination of features in one client you will scarcely be able to go wrong. But as nature is not often so lavish with her attributes of beauty, you must train yourself to search out the most pleasing aspects of your most difficult subjects.

We have all read poetry about the beauty of eyes, but I have

never read a single stanza praising someone's ears. I know a man has two ears, but I like to lose sight of that fact in most of my photographs. If Mr. Toujours Front-face will, for one week, take every sitter so that only one ear is seen he will see, in his own work, possibilities that could not be illustrated in any better way. In turning the head of a model, what are we looking for? Undoubtedly we should be regarding the outline of the side least shown, noting the contours of forehead, cheek and chin. With most subjects, however plain, these curves are a complete index to the shape of the face, and give the idea of roundness which the front face, with the ears as sentinels, succeeds in destroying. I have always found the second ear an excrescence on a beautiful outline. When it happens to protrude an unlovely lobe out of a chubby face (I only notice this in the negative), I give strict orders to the retoucher to obliterate the offence.

I seem to be approaching an ideal point of view by a process of elimination. This is not a bad method either, for when one has ruthlessly ruled out everything that is crude and inelegant, whatever remains must of necessity contain the artistic element inherent in the subject. The front face has flattened itself out, and I have taken one ear from you. What shall we do with the rest of the face? Remember that your first consideration in the point of view is the outline. Your eye probably needs training in this, as in other respects. It isn't at all satisfactory to pose a subject in the studio and then expose the plate from a foot lower than you saw it with your eyes. In searching for a good outline, do not merely turn the head of the subject. Tilting, ever so slightly, to right or left, backwards or forwards, frequently makes a wonderful difference, and, of course, raising or lowering the camera alters the drawing considerably. If you wish to take a man as if his chin grew out of his chest and his shoulders were hung on to his ears keep your camera very high. Although this style of portrait is acceptable to Arnold Bennett—when produced by Pirie Macdonald—the general public are not educated up to that standard yet. For good lines of chin, neck and shoulders a low camera is essential.

The eyes, nose and mouth are to be considered in conjunction with the outline. Fortunately the eyes may be turned, raised or lowered, but the same cannot be done with the nose, which may also be fortunate. Observe what change can be made in the nose by raising or lowering the chin, and take care when using a low camera that you do not disclose an ugly view of the nostrils. The mouth is invariably too big, and the only way I know of making it appear neater is by the process known to artists as "foreshortening," which I will treat exhaustively later.

A few hints or guiding principles in selection may be useful. Although I am taking the factors in composition seriatim, in practice one does not do that. What is called "posing" cannot be properly considered apart from "lighting," and so on. Well, then, let us think of a very stout man. Turn him well away from the light and seat him so that he cannot lean back. Get all the neck you can with low observation. Turn him so far away that you will get the extreme length of his snub nose without exposing his unshapely profile and double chin unduly. Avoid front light with this type of face. Some photographers adopt exactly the wrong method with this problem. If you fill in the hollows, *either with light or lead pencil*, you get a turnip effect. Use light sparingly and secure every bit of detail in the face. Here I'll give a tip that is worth noting. Ordinarily the lighting carries over the nose and slightly illuminates the cheek bone on the shadow side. With the fat subject keep the lighting abrupt, so that the drawing on the dark cheek is lost. Make a portrait on these lines and the eye of the superficial observer will be deceived. The light part is all that is seen, and the suggestion given that the face is very much less broad than it really is.

Let us now think of the opposite extreme, a thin face with very sharp features. From the tip of the nose to the ears are steep planes that could only be faithfully rendered if taken and viewed stereoscopically. Obviously, then, we have to keep well away from the front view. How much we may turn away is to be determined by what we think of the features. If the face is cadaverous and its owner still young, let in sufficient front light to fill in the hollows. If nose and chin are good Rembrandt lighting may be used with good effect. The broad rule in lighting is: faces with good projections may look *towards* the light, low projections should be turned *from* the light.

The severe profile is very exacting, although very beautiful when one has the right subject. Think of the head and hair in this respect as well as the face. Most men need a lot of instruction on feminine "points." I never have the faintest doubt about the better side of a lady's head, the hair dressing tells me that. And the one she thinks the better is the one she is paying me to photograph. Be very careful with the ladies' hair. Top lighting or fancy effects are apt to suggest greyness.

So far I have only been dealing with the bust portrait. As the new scholar at the Sunday school said, man's chief end is the one with the head on. The same selective process obtains where more of the figure is disclosed. In all compositions seek variety. Don't have meaningless repetitions. One day I had been pointing out to an assistant some faults of his in this respect. A little later I overheard him saying to the dark room lad: "A man has two of everything, but for heaven's sake don't let the boss hear you say so."

J. Eppel.

The Royal Photographic Society's house at 35, Russell Square, W.C.1, is being redecorated, and many alterations are being made in the library, artificial light studio and other rooms. Additional bookcases have been placed in position in the library, and an up-to-date and really useful card index of the Society's store of literature is being prepared.

The £3,000 All-British Competition Awards.—A complete list of awards made in this competition has reached us in the form of a poster attractively printed and specially designed for a photographic dealer's shop window. The list of about four hundred names and addresses is too lengthy to reprint in our columns, but space may be found for the winners of the six first prizes of £100 each. These were: W. Lightbody, Hamilton, N.B.; C. C. Davis, Portsmouth; A. Marshall, Bradford; G. F. Prior, Chingford; S. W. Shore, Finchley; and T. H. Mew, Sunderland. Mr. Prior also won the gold medal. The winner of the first prize (£50) in the Junior Section was A. D. Hitchen, Newcastle. The list is one that should be secured by all dealers. The names and addresses of the dealers who won prizes have also reached us. The cash prizes in each of the classes, 1 to 6, were as follows:—1st, £25; 2nd, £6 5s.; 3rd, £2 10s.; 4th, £1 5s.; and the winners were:—Class 1: 1st, J. Loboar, Hamilton; 2nd, J. C. Thompson, Southsea; 3rd, Godden, Streatham, S.W.; 4th, Thomas and Foster, Poole. Class 2: 1st, J. C. Thompson, Southsea; 2nd, Boots Chemists, Finchley, N.12; 3rd, F. Bannister, New Cross, S.E.14; 4th, Chrystold, Ltd., Bootle. Class 3: 1st, T. C. Bridges and Son, Bradford; 2nd, O. F. Moss, Emmanuel Road, S.W.12; 3rd, H. G. Thompson, Leicester; 4th, T. H. Fleming, Newcastle-on-Tyne. Class 4: 1st, City Sale and Exchange, Liverpool Street Arcade, E.C.2; 2nd, J. Fallowfield, Ltd., Charing Cross Road, W.C.2; 3rd, Ordered direct, no award; 4th, J. C. Phelp and Son, Walthamstow, E.17. Class 5: 1st, Horne's Camera Mart, New Broad Street, E.C.2; 2nd, A. P. Taylor, Eastbourne; 3rd, G. Coverdale's Sons, York; 4th, J. Fallowfield, Ltd., Charing Cross Road, W.C.2. Class 6: 1st, J. Walton, Sunderland; 2nd, Parkes Drug Stores, Holloway Road, N.19; 3rd, J. Baxter and Co., Grangemouth; 4th, Peacock and Co., Sittingbourne. Class 7 (Juniors): 1st (£7 10s.), Mawson and Proctor, Newcastle-on-Tyne; 2nd (£3 15s.), W. Middleton and Ashman, Bath; 3rd (£2 10s.), Mason's Photo Stores, Leeds; 4th (£1 5s.), Nash Kenyon, Southport. The second competition is now in full swing, and special literature concerning it is being published. Full particulars may be had from the Secretary, £3,000 All-British Competition, 4, Oxford Street, London, W.1.

SOME NEW SENSITIZERS FOR THE DEEP RED.

(Communication No. 147 from the Research Laboratory of the Eastman Kodak Company.)

In the course of work extending over a number of years, a great number of new dyes derived from quinoline have been prepared and tested for their sensitizing power. A number of compounds prepared in the course of this investigation have been described in a paper by H. LeB. Gray and G. Wiltekunst on "The 6-Alkyloxyquinaldines."[1] The purpose of the present paper is to describe three of the new sensitizers which have been selected as having interesting properties, two of which it is proposed to place upon the market.

1. *Naphthacyanole* (1,1' *Diethyl Di-β-Naphthcarbocyanine nitrate*).

This dye was prepared as follows:—

A solution of 5 grams of β-Naphthquinaldine ethiodide and 5 grams of quinoline ethiodide in 550 c.c.s. of boiling ethyl alcohol (95 per cent.) was treated with a mixture of 4 c.c.s.

Fig. 1.—Beta-naphtha-cyanole.

formaldehyde (40 per cent.) and 60 c.c.s. of 10 per cent. alcoholic potash. The dye separated out in the form of little green needles, which on account of their insolubility were converted into the nitrate. This was accomplished by suspending a small amount of the dye in glacial acetic acid, (75 c.c.s.), and adding 200 c.c.s. of 10 per cent. nitric acid, allowing the mixture to digest for a time (½ hour), and then filtering off the undissolved crystals. The solution was shaken thoroughly with 1 c.c. of 10 per cent. silver nitrate, and the silver iodide filtered off. The dye was precipitated immediately with ammonium hydroxide and re-crystallised from methyl alcohol.

This dye sensitizes powerfully both when added to the emulsion and when used for bathing ready prepared plates. A spectrum, shown in fig. 1, shows a strong maximum in the deep red at 690 μμ and a sensitizing power for the green appreciably less than that shown by pinacyanol. The dye keeps well, and is quite suitable for use in the place of pinacyanol where the extreme red sensitiveness is an advantage.

2. *Acetaminocyanole* (1,1' *Diethyl-6,6'-Diacetaminocarbocyanine Iodide*).

This dye was prepared as follows:—

A solution of 5 grams 6-acetaminoquinaldine ethiodide and 5 grams quinoline ethiodide in 200 c.c.s. of boiling ethyl alcohol, was treated with a mixture of 20 c.c.s. of sodium ethylate (1 gram sodium in 50 c.c.s. absolute ethyl alcohol) and 5 c.c.s. of formaldehyde. A blue green solution was formed, and green crystals separated on cooling. These were re-crystallised from methyl alcohol.

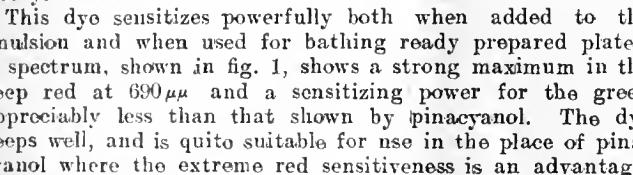

Fig. 2.—Acetamino-cyanole in emulsion.

The dye obtained was found to sensitize powerfully when added to an emulsion giving a maximum at 730 μμ. Its spectrum is shown in fig. 2. When an attempt was made to use this dye in water solution for bathing plates, a very curious result was obtained, the spectrum obtained being that shown in fig. 3, and corresponding obviously to an entirely different dye. Moreover, it was found that in the preparation of the dye, it was necessary to be careful to keep the water content to a minimum, as otherwise the dye had not the characteristic sensitizing maximum at 730 μμ, but gave a result similar to that obtained when bathing plates in water solution. The probable explanation of these anomalies is that the dye is hydrolysed by water, the acetyl radicle being hydrolysed off. While the dye, therefore, has some value when used for emulsions, since the plates prepared appear to keep their characteristic properties, it is not thought that it will be of general value owing to its instability.

A compound is described by Mills and Pope[2], which was prepared by the condensation of 6-acetaminoquinaldine ethiodide

Fig. 3.—Acetamino-cyanole: bathed plate.

and quinoline ethiodide with formaldehyde and alkali, and crystallises in minute green needles. It senstitizes at 6,300-6800 and more weakly at 5200-6300, and thus appears to be an entirely different compound from that described above.

3. *Kryptocyanine.*

This dye was prepared by the condensation of lepidine ethiodide.[3] On re-crystallising from chloroform small bronze crystals are obtained. On trial this proved to be the most remarkable sensitizer yet discovered. A great deal of time was expended in purifying it to prevent a fogging action on the emulsion, since, when tested in the usual concentration, 1 in 25,000, it gave severe fog, though sensitizing with great power with a maximum of 760 μμ. It was found, however, that the dye was being used in far too great a concentration, and by the use of only 1-20th of the amount required for pinacyanol excellent results were obtained. The spectrum is shown in fig. 4. For bathing solutions a concentration of 1 in 500,000 is recommended. The addition of either ammonia or alcohol was found to be a disadvantage.

Tests were made for the extension of the spectrum with kryptocyanine into the extreme infra red. It was found that although its maximum is at a considerably longer wave-length than that given by dicyanine, and although up to 850 μμ its sensitizing power is greater than that of dicyanine, yet

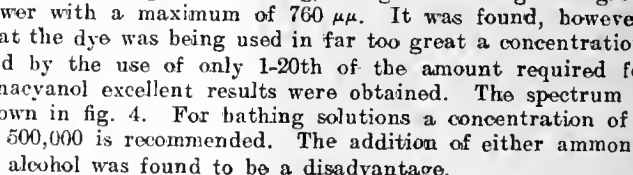

Fig. 4.—Kryptocyanine.

beyond this point dicyanine shows a greater sensitizing power, and above 900μμ Kryptocyanine is almost useless, while dicyanine employed according to the directions given by Dr. Meggers is still effective. Nevertheless, Kryptocyanine represents a very great advance in the preparation of photographic materials sensitive to the extreme red. Since it confers no green sensitiveness, and, indeed, the materials sensitized with it have very little sensitiveness below 680 μμ, infra

1. Forthcoming in Jour. Amer. Chem. Soc.

2. "Phot. J.," 40. p. 253 (1920).

3. "The Kryptocyanines, a New Series of Photo-Sensitizing Dyes," by E. Q. Adams and H. L. Haller, Jour. Amer. Chem. Soc., 1920, vol. 42, p. 2661.

red effects in ordinary photography can be obtained by the use of a strong yellow filter only, and employed in this way, it is possible to give very short exposures, one second at *f*/8 being quite satisfactory in bright sunlight. The results obtained are those characteristic of photography in the infra red, blue skies appearing dark, and green foliage very bright, so that a tree covered with spring leaves appears as if in blossom, and the grass on the ground as if it were snow.

It is probable that the dye will have applications in astronomy. At the present time, stars are classified by their colour index, this being the relation of the photographic magnitude determined in the violet to the photo-visual magnitude determined in the yellow-green, and determination of the extreme red magnitude at 770 $\mu\mu$ by the use of Kryptocyanine will probably extend the value of such studies. Undoubtedly numerous other applications will be found for this dye.

The Naphthacyanole and the Kryptocyanine will be added to the list of synthetic organic chemicals supplied by the Research Laboratory of the Eastman Kodak Company.

C. E. K. Mees.
G. Gutekunst.

THE CORRECTION OF LENSES FOR CHEMICAL FOCUS.

Many photographers probably possess a lens which gives satisfactory definition in ordinary use, but which will not make sharp enlargements, owing, generally, to what is called "chemical focus," i.e., the focus of the lens for the "chemical" rays which affect the sensitive emulsion does not coincide with the focus for visual rays by means of which the focussing was made. This is often the case with old lenses, particularly R.R.'s and portrait lenses and some of the earlier anastigmats. In the old days when enlargements were made by the light of oil and gas lamps, which was not rich in ultra-violet rays and often possessed a reddish or yellowish tinge to the eye, the optician brought the focus for the red and blue rays into coincidence. Nowadays, with the more efficient mercury vapour and arc lamps, which are rich in ultra-violet rays, correction for the lens has to be made for the yellow and ultra-violet rays. Consequently, some correction has to be applied to the old lens if sharp enlargements are to be made. The amount of this correction will vary with the type of lens, focal length and degree of enlargement. It will be shown in this article how, when the correction has been found for a particular lens under one set of conditions, the correction under every other condition can be calculated.

There are two simple ways of determining the correction; the first is to focus an enlargement sharply by the eye, mark the position of the lens, measure the distance and size of object and image, and then slightly shift the lens and test the focus on a piece of bromide paper. A few trials should furnish the correct position of the lens for sharpest focus pretty accurately. In general the lens will require to be moved towards the enlargement. The amount and direction of the displacement of the lens from its first position should now be measured.

Let u_1 and v_1 (fig. 1) be the distances of enlargement and copy respectively from the lens, of focal length f_1, and m_1 the magnification. These

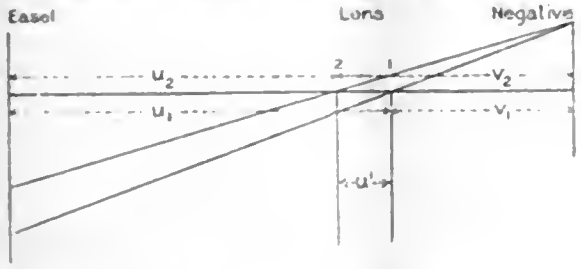

Fig. 1.

all refer to the visual adjustment; let the same letters with suffix 2 refer to the photographic adjustment, and let $u_2 = u_1 + u'$, etc. Then we have from the usual formulæ:

$$u_1 = (1 + m_1) f_1 \qquad u_2 = (1 + m_1 + m') (f_1 + f')$$
$$v_1 = (1 + 1/m_1) f_1 \qquad v_2 = (1 + 1/(m_1 + m')) (f_1 + f')$$

and as nothing has been moved but the lens $u_1 + v_1 = u_2 + v_2$, so

$$f_1 (2 + m_1 + 1/m_1) = (f_1 + f') (2 + m_1 + m' + \frac{1}{m_1 + m'})$$

$$\text{or } f_1 \left(1/m_1 - 1/(m_1 + m')\right) = f_1 m' + f' \left(2 + m_1 + m' + 1/(m_1 + m')\right)$$

Now all the quantities denoted with a dash are small compared with the same quantities with suffixes, being in the nature of correction terms, hence a sufficient accuracy will be obtained if we neglect products of two small quantities, so we may write:

$$f_1 \frac{m'}{m_1^2} = f_1 m' + f' (2 + m_1 + 1/m_1)$$

or:

$$m' = -\frac{f'}{f_1} \cdot \frac{2 + m_1 + 1/m_1}{1 - 1/m_1^2}$$
$$= -\frac{f_1'}{f_1} \cdot \frac{(m_1 + 1) m_1}{m_1 - 1}$$

and: $u' = u_2 - u_1 = m' f_1 + (1 + m_1) f'$

$$= -f' \cdot \frac{m_1 + 1}{m_1 - 1} \quad . \quad . \quad . \quad (i)$$

Now u' has been measured, so that we find the error in the focal length:

$$f' = -\frac{m_1 - 1}{m_1 + 1} \cdot u' \quad . \quad . \quad . \quad (ii)$$

If the lens is to be used at any other magnification or enlargement M, the formula (i) tells us the amount of correction to be applied to u_1, i.e., the distance the lens has to be moved after focussing, viz.:

$$f_1' \cdot \frac{M - 1}{M} \cdot u' = \frac{m_1 - 1}{m_1 + 1} \cdot \frac{M + 1}{M - 1} \cdot \quad (iii)$$

Note as to the sign. If u' comes out to be negative, it means that the lens must be moved nearer to the enlargement. In this case f' is positive, i.e., the lens has a longer focus for the chemical rays than for the visual, or, in the language of the optician, is "over corrected." Such will usually be the case.

A second method of measuring the focal error is more direct if a little more troublesome. For this a test object (fig. 2) must be prepared, consisting of lines ruled in two directions mutually at right angles, with regularly spaced lines, say, a tenth of an inch apart. It may be prepared in several ways: A clean piece of glass may be blackened with varnish mixed with lamp-black, or a plate may be fogged, developed, fixed, washed and dried; the lines can be cut with a sharp knife. Or an unexposed plate may be fixed, cleaned and dried, and the lines ruled on the clear gelatine film. The lines should be ruled parallel to the edges of the plate and one of the central lines, which will be horizontal in the enlarger, should be distinguished by making it double, or in any other convenient way. It will also be convenient to mark the upper part of the plate. The paper on the easel should be tilted, preferably at 45 deg., to simplify calculations, to the lens axis. If now the central horizontal line of the test object is focussed sharply on the inclined screen and the exposure made on bromide paper, it will be found, if the lens has chemical focus, that the central line is not sharp, but some other line is. Suppose, e.g., that the second line from the centre is sharpest, there is then an error in focus of .2 in., multiplied by the enlargement, which is found from the space between the vertical lines on the enlargement. If this is, say, .3 in., the magnification is x3, and so the full error in focussing is .6 in. To find the correction for any other magnification a different formula is necessary.

With the same notation as before,

$$v_1 = f_1 (1 + 1/m_1)$$
$$v_2 = (f_1 + f') (1 + 1/(m_1 + m'))$$

Here $v_2 = v_1$, so

$$f_1 (1/m_1 - 1/(m_1 + m^1)) = f^1 (1 + 1/(m_1 + m^1)).$$

With the same agreement as to approximation as before, this gives:

$$1 \cdot \frac{m^1}{m^2} \quad f^1 \cdot (1 + 1/m)$$

or:

$$m^1 \quad \frac{f^1}{f_1} \quad . \quad m(m+1) \quad . \quad . \quad . \quad (iii)$$

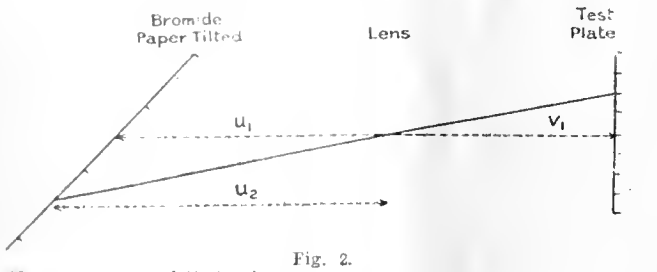

Fig. 2.

Now: $u = f(1 + m)$

$u + x = (f + f^1)(1 + m + m^1)$

where x is the "error in focus" found as above:

Subtracting, $x = f m^1 + f^1 (1 + m)$

Substituting for m^1 from (iii)

$$x = f^1 (m+1)^2$$

$$\text{or } f^1 = \frac{x}{(m+1)^2} \quad . \quad . \quad . \quad (iv)$$

the error in focal length.

For any other degree of enlargement, the correction for u is:

$$\frac{x}{(m+1)^2} \cdot \frac{M-1}{M+1} \quad . \quad . \quad . \quad (v)$$

The figure indicates the direction in which x, and therefore f, are reckoned positive ("over corrected").

Formula (iv) also indicates the adjustment to be made if the easel is moved to get correct focus, viz.:

$$\frac{x}{(m+1)^2} \cdot (M+1)^2 \quad . \quad . \quad . \quad (vi)$$

$$\text{or } -u^1 \cdot \frac{m-1}{m+1} \cdot (M+1)^2 \quad . \quad . \quad (vii)$$

according as x or u^1 is the quantity measured.

(iii) and (v) give the correction to be applied to the *lens* position, (vi) and (vii) the correction to the *easel* position. Either one or other may be used, not both simultaneously. To avoid all trouble about signs, it will be observed that the direction of the movement of adjustment, whether of lens or easel, is always the same direction, whatever the magnification.

It may also be necessary to mention that the front of the lens should always be turned towards the enlargement if the best possible definition the lens will yield is to be obtained.

H. L.

THEORY AND PRACTICE OF DEPTH OF FOCUS.

I

[The rules and formulæ relating to depth of focus have perhaps been the subject of a greater number of articles in the photographic Press for many years past than any other section of photographic optics; and certainly no question concerning the use of a lens has aroused so much controversy. In the present series of chapters the endeavour will be to put before the student an exposition of depth of focus based on first principles, and in terms of geometrical construction within the image space. Much of the confusion which exists in the literature of depth of focus arises from the mixture of two views on the subject. In most English writings depth is treated from the standpoint according to which a certain definite circle of confusion is adopted as permissible in photographic negatives or prints, large or small, which are to be regarded as sharp. On the other hand, among Continental writers it is generally held that the permissible disc of confusion is variable, according to the size of the photograph, or rather according to the distance from which it is to be viewed. There is nothing inconsistent between the two standpoints. Both have their advantages, and as will be seen from the present chapter and from a later one dealing with depth according to the more modern Continental view, both have their limitations for practical purposes. It will be seen that formulæ in accordance with the adoption of a variable disc of confusion may be directly derived from those worked out for a chosen diameter of disc. In this first chapter the phenomena of vision, consideration of which has not received the attention they deserve by English writers, are chiefly dealt with. Chapter II. will deal with the formulæ and practical significance of hyperfocal distance.]

In depth of focus we have a branch of photographic optics which has its obvious practical importance yet cannot be treated by rigid optical formulæ, since it is based on standards which in turn depend upon the acuteness of vision of the human eye and also upon the distances from which prints and enlargements are viewed. Thus, apart from the differences between the eyes of different observers, the purpose for which a photograph is required has to be taken into consideration. Plainly, the same rules cannot be employed for determining the permissible amount of unsharpness in a photograph (even though it may be a large one) which is to be closely scrutinised for its rendering of detail, as for one which is to be viewed from a distance suitable for appreciating its general effect and perspective. For this reason it is necessary to consider the conditions of viewing as much as those prevailing in the taking of the negative when seeking to determine the rules which can be adopted as a guide to the production of adequate sharpness of definition.

The subject divides itself into two parts, the first of which will be dismissed very much more shortly than the second. The first, which we call *depth of definition*, relates to the distance which the focussing screen or plate receiving a sharp image can be moved towards or away from the lens without exceeding the limit of permissible unsharpness. This depth, which is not of much importance in practice, is always a small distance, i.e., ranges from a fraction of an inch to a few inches.

The second part relates to distances in the subject photographed, that is, the distance which can exist between an object and one further from the camera whilst obtaining both in sufficiently sharp focus. The space between points at these distances is what is commonly understood by *depth of focus* (*depth of field* is a better term, sometimes used), and under the conditions of ordinary photography is large, ranging from a few feet to many yards.

Before dealing with these two aspects of the subject, it is necessary to consider briefly certain properties of the eye which are exhibited in the viewing of objects or of flat representations of them, e.g., photographic prints or enlargements.

Sharpness of Vision.

It is a familiar fact that the eye is unable to distinguish the form of a small object at a distance which is very great relatively to the size of the object. A shilling, which measures just under 1 in., if viewed from a distance of about 100 yds. is not recognisable as a circular disc, but appears to the average eye as a point. Thus we can imagine that at a distance of 100 yds. a painting composed of 1-in. discs of colour would appear to lose its disc structure owing to the separate discs becoming unrecognisable at this distance.

Fig. 1 illustrates this phenomenon of vision. It is a half-tone reproduction of a photograph made with a screen of ruling which yields blocks chiefly composed of dots of diameter about 1-16th of an inch. Looked at from the customary viewing distance of about 12 in. the reproduction is so broken up by the dot structure as scarcely to

disclose the subject. But if viewed from the distance of a few feet—about 12 ft., i.e., 2,000 times the diameter of the white dots—the dots cease to be recognisable as such and the details in the prints, so to speak, "join up" to a surprising degree.

Now the image formed by a photographic lens of a subject containing parts at different distances from the camera, bears a certain resemblance to these half-tone proofs, unless a very small stop is used. The lens, as we know, can bring to a sharp point focus only pencils of rays from an object at some one distance. Pencils from nearer or more distant objects are brought to a focus respectively behind or in front of the point image of the object focussed, so that the whole image, on a reduced scale, exists in space. The image obtained on the focussing screen is a cross section of this image, and hence the points of the subject nearer or further than the object focussed are represented photographically by the discs which result from the interception (by the focussing screen) of

Fig. 1. Illustrating limited sharpness of vision.

The discs forming the half-tone reproduction are about 1-16th of an inch in diameter, and at a distance of about 12 ft. cease to be recognisable.

convergent or divergent pencils or cones of rays whose meeting points or foci are respectively behind or in front of the screen.

Just as in the case of our half-tone proofs, a photograph is sharp if these discs are unrecognisable by the eye. This requires that the photograph shall be viewed at a distance which is great relatively to the size of the discs; or, the other way about, that the discs be small relatively to the distance at which the photograph is viewed. In other words, the appearance of sharpness in a photograph is dependent on the limited sharpness of vision of the eye.

According to the physiologists, this limited sharpness of vision is explained by the size of the minute cones which form the sensitive system in the retina. If an object is so remote or so small that its image formed by the lens of the eye falls wholly within the area of one of these cones, there can be no delineation (by the mechanism of the eye) of the form of the object. It is found that this is the case when an object is viewed from a distance equal to or greater than about 3,400 times the greatest dimension of the object. At this relative distance lines drawn from each end of an object to meet in the eye include the very small angle of 1′ (the 5,400th part of a right-angle). The angle requires to be at least 5′ in order that the object shall be sharply perceived. Hence objects which subtend angles at the eye from 1′ to about 4′ are perceived more or less indistinctly, which explains the paradoxical truth that it is the limited ability of the eye to see sharply which causes a broken up image (e.g., containing optical discs of confusion) to appear sharp.

In most of the writings on depth of focus a disc of confusion of 1-100th of an inch (sometimes 1-200th or 1-250th) is taken as the maximum permissible. These correspond with angles of about 3′ and 1′, if the photograph is viewed from a distance of 12 in., and, roughly speaking, correspond with fair and critical sharpness. But it follows from the property of the eye which we have just described that the value admitted for the maximum disc of confusion should vary according to the viewing distance, so that the angle subtended at the eye may be kept within the permissible limits.

NOTE.—For purposes of calculation, the arbitrary method of measuring angles in degrees, minutes and seconds cannot be conveniently used. It is necessary to express the size of the angle by the arc method (the so-called "circular measure"), according to which the measure of the angle is the part of the circumference of the circle included between two radii of the circle (when these radii include the angle at the centre)

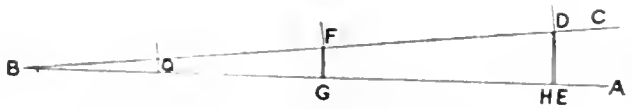

Fig. 2.—Illustrating arc or circular measure of an angle.

The ratio of any arc $D E$ (or $F G$) to the corresponding radius $B E$ (or $B G$) is the arc measure of the angle $A B C$. The angle Q in the figure is 5°. It will therefore be clear that in the case of such small angles as 5′ (one-sixtieth of that shown) the line $D H$ practically coincides with the arc $D E$.

divided by the radius. Fig. 2 illustrates the circular measure of the angle Q, included between the lines $A B$ and $C B$. If from B, as centre, the arc $D E$ is drawn, then the circular measure of the angle Q is the ratio of the arc $D E$ to the radius $B E$. In like manner it is equally the ratio $\frac{F G}{B G}$ where $F G$ is the arc of a circle, also having its centre at B.

If the angle Q is very small its size expressed in circular measure is practically the same as the so-called trigonometrical ratio, the tangent of the angle, that is, the ratio of the perpendicular to the base in a right-angled triangle. This is also illustrated in fig. 2, where $D H$ has been drawn perpendicular to $B A$. The ratio $D H : B H$ is then the tangent of the angle Q. In the drawing it will be seen that the perpendicular $D H$ differs slightly in length from the arc $D E$, and that the base $B H$ is very slightly less than the radius $B E$. The tangent of an angle is practically equal to the circular measure of an angle in the case of angles less than 5 deg. As the angles concerned in sharpness of vision are much smaller still, viz., from 1′ to 4′, the tangent may be considered equal to the circular measure: the values of the former (the so-called "natural tangents") may be taken from tables of logarithms, etc., such as "Chambers' Mathematical Tables." It will thus be clear that the measure of such very small angles is simply the dimension of the object divided by its distance, a relation which requires to be kept in mind in considering the depth formulæ to be given

Limited Accommodation of the Eye.

The second property of the eye which is directly related to depth of focus is its limited power of accommodation in viewing very near objects. Putting aside defects of vision, such as short-sightedness, the normal eye has extraordinary powers of adjusting the focal length of its fluid lens to objects at distances beyond a certain minimum, but in the case of the average adult, the nearest distance at which an object can be comfortably and distinctly viewed is from 10 in. to 14 in. This distance becomes greater from 50 years of age onwards, beyond which age the normal distance (which we may take as 12 in.) is preserved by the wearing of suitable spectacles. This limit of nearness for distinct vision is of importance in depth of focus, since it follows that both the very smallest photographs and larger ones, up to about 10 in. × 8 in., are necessarily held at the same distance of about 12 in. from the eye for comfortable viewing. Hence it follows that a 10 in. × 8 in. enlargement from a small negative requires to be of as fine optical definition as a contact print from the negative. On the other hand, in the case of enlargements from negatives of fair size themselves, it is almost always the case that they are viewed from distances proportional to their size, and hence may be of correspondingly coarser optical definition without apparent loss in sharpness.

We may now set down in the form of a table the sizes of the discs which appear as points (sharp definition) when viewed from the two selected distances of 12 in. and 30 in., and also of discs which represent lesser but still reasonable sharpness when viewed from these same distances, at larger angles 1′ 12″ to 4′.

TABLE I.

Angle subtended by disc of confusion.		Tangent * of angle	Circle of confusion indistinguishable	
Minutes and seconds.	Circular measure.		at 12 in.	at 30 in.
1′	$\frac{1}{3438}$ = .00029	.00029	$\frac{1}{286}$	$\frac{1}{114}$
1′–8″	$\frac{1}{3000}$ = .00033	.00033	$\frac{1}{250}$	$\frac{1}{100}$
1′–42″	$\frac{1}{2000}$ = .00050	.0005	$\frac{1}{166}$	$\frac{1}{66}$
2′	$\frac{1}{1724}$ = .00058	.00058	$\frac{1}{144}$	$\frac{1}{58}$
2′–51″	$\frac{1}{1200}$ = .00083	.00083	$\frac{1}{100}$	$\frac{1}{40}$
3′	$\frac{1}{1149}$ = .00087	.00087	$\frac{1}{96}$	$\frac{1}{38}$
3′–26″	$\frac{1}{1000}$ = .001	.001	$\frac{1}{83}$	$\frac{1}{33}$
4′	$\frac{1}{862}$ = .00116	.00116	$\frac{1}{72}$	$\frac{1}{28}$

* = size of object (i.e., disc of confusion) divided by its distance from eye.

From the above brief consideration of the limitations of average human vision, we can now turn to the rules which respectively apply to depth of definition and depth of focus, using these terms in the senses already defined.

Depth of Definition.

The formula for the distance through which the focussing screen may be moved without exceeding a given standard of sharpness of definition in the case of a flat object may be obtained from the following construction. In fig. 3 the image of a point O is formed at F at a distance v

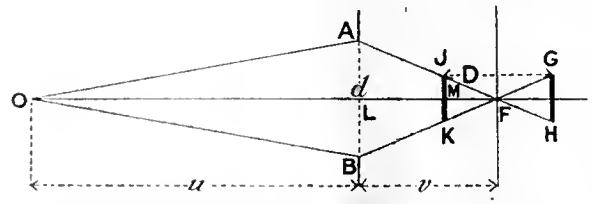

Fig. 3.—Illustrating depth of definition.

If a point image of a point O in a *flat* object is formed at F, and if the admissible disc of confusion is c, the focussing screen may be anywhere within the distance D = depth of definition.

from the lens diaphragm $A\,B$ of diameter d (strictly from the exit node of the lens). Let $G\,H$ and $J\,K$ be positions of the focussing screen in which the point image becomes a disc of the largest admissible diameter, c. The distance D is the depth of definition: and it is clear from the construction that the depth extends equally on each side of the focus F.

From the construction

$$\frac{A\,B}{J\,K} = \frac{L\,F}{M\,F}$$

$$\text{that is } \frac{d}{c} = \frac{v}{\frac{D}{2}}$$

$$\text{Therefore } \frac{D}{2} = \frac{c \times v}{d}$$

$$\text{and } D = \frac{2c \times v}{d} \quad . \quad . \quad . \quad . \quad (1)$$

If the object O is at a great distance relatively to the focal length of the lens, the image is formed at a distance f equal to the focal length of the lens so that formula (1) becomes:

$$D = \frac{2c \times f}{d}$$

Since f/d is the ratio representing the F No. of the lens

$$D = 2c \times \text{the } F \text{ No.} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

which shows that the depth of definition is the same for every lens having the same F No., and is independent of the focal length. It varies with the standard adopted for permissible unsharpness.

For example, adopting a disc of confusion of 1-100th of an inch, the depth of definition with an $f/4.5$ lens is

$$2 \times \frac{1}{100} \times 4.5 = .09 \text{ in.}$$

If the image is larger than the object, as in copying-enlarging, the depth is greater, since in this case v in formula (1) becomes equal to $f + Rf = f(R + 1)$ where R is the number of times of enlargement. Hence

$$D = \frac{2c \times f(R+1)}{d} = 2c \times (R+1) \times F\,\text{No.} \quad . \quad . \quad (3)$$

For example, adopting a disc of confusion of 1-100th of an inch when copying-enlarging nine times with an $f/4.5$ lens, the depth of definition is

$$2 \times \frac{1}{100} \times 10 \times 4.5 = .9 \text{ in.}$$

The considerations already set forth in respect to the relation of the value of the permissible disc of confusion to the viewing distance and also to the required standard of sharpness will have shown the value of c to be employed in the above formulæ. For example, for prints to be examined for detail from the average viewing distance of 12 in., the maximum value of c is about 1-250th of an inch, whilst for the same standard of sharpness in, say, a 20 in. × 16 in. enlargement to be viewed not nearer than 2 ft., c may be twice as great, say, 1-120th of an inch. For less critical degrees of sharpness, correspondingly greater values of c may be employed, as shown in Table I.

It must be repeated that the formulæ above given apply only to a flat object, as in copying a drawing or enlarging a negative. Moreover, they apply strictly to images formed on or near the lens axis, but, providing the lens is free from curvature of field, may be regarded as holding good over the angles covered by lenses in ordinary photographic work. G. E. B.

(To be continued.)

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

A HYDRAULIC AGITATOR AND SOLUTIONER.

A NOTE IN THE "PHOTOGRAPHIC JOURNAL."

THE apparatus described in the following note was evolved to meet laboratory demands for a simple stirring device. When liquids have to be kept in continuous agitation it is customary to use a small motor, with shafting and pulley wheels, to actuate a propeller or bent rod immersed in the liquid. This is an expensive and comparatively complicated way of doing the work, as often as not the propeller breaks the beaker or thermometer, and it cannot be used with narrow-necked vessels.

Referring to the diagram, fig. 1 shows a simple water pump, which, used in conjunction with the bulbs (R, S. T) of figs. 2, 3 and 4, has a variety of applications. The bulb (A) is fitted with a syphon (BK), a water inlet (H), an attachment tube (O), and two narrow U-tubes (CE) and (DF). In normal use for agitating liquids and suspensions in bottles, flasks, or beakers, the bulb attachment in fig. 2 is connected by a rubber tube with tube (O) of fig. 1. The tube (DF) is corked at (F). Water admitted at (H) rises in (A), displacing the air through tube (CE). When (A) is full, the water runs into (CE), sealing it, and also flows over the top bend of the syphon tube (BK). It now flows down the limb (K), which is in such a diameter that the water passes away faster than it is supplied at (H). In so doing it creates a partial vacuum in (A) which is relieved by a flow of air from (R), with the result that the liquid to be stirred rises in (R). When it reaches the constriction (S), the sudden check prevents air flowing to (A) and the momentum of the water column in (BK) momentarily increases the vacuum, so that the water in (CE) is sucked into (A), leaving the bulb open

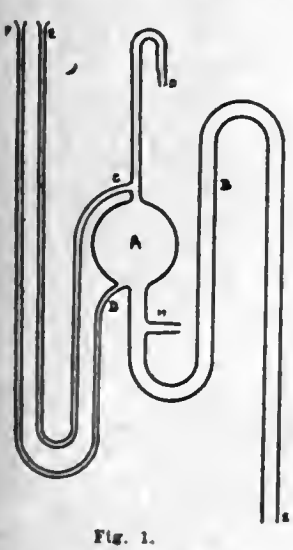

Fig. 1.

Fig. 2.

Fig. 3.

to the atmosphere once more. Air enters rapidly, breaking the water column in (BK) and allows the water in (R) to flow back into the reaction vessel. The cycle is then repeated.

The removal of the liquid from the reaction vessel has been objected to on certain grounds, and to meet the demand for an attachment to stir the liquid *in situ* the bulb in fig. 3 has been devised. The bulb is connected by (P') to (O), as above, and the cork moved from tube (CE) to (DF). Admission of water at once seals (DF), compressing the air in (A) and driving liquid through the holes in the base of (R') into the beaker. The syphon action then comes into play, emptying (A) and refilling (R') with solution. The tube (FD) is cleared when (R') is full, and the cycle repeats.

It will be seen that such a device, capable of delivering a series of air compressions and rarefactions, can be of great use to photographers. The tube (O) can be connected to a rubber bladder and the expansions used to rock a dish. The bulb attachment can be used to stir hypo and toning baths, as in fig. 4, a method greatly preferable to dish rocking.

To a photographer the most important application is for dissolving chemicals. For making up developers, dissolving hypo, metabisulphite, sulphite, etc., the device is invaluable. The chemicals are placed, with the requisite water, in their bottle, the solutioner (fig. 2) inserted in the top, and in a few minutes everything is dissolved. Developers can be made up rapidly without shaking or the use of hot water.

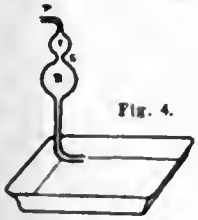

Fig. 4.

The apparatus can be constructed from glass and wood, cheaply and conveniently, and requires little water to actuate it. A patent has been applied for, and it is hoped to find many other applications for the device.

K. C. D. HICKMAN, B Sc.

Photo-Mechanical Notes.

Contact Reproductions by Reflected Light.

FURTHER details of the Manul process are disclosed in the patent (No. 156,692) taken out by Max Ullmann, and supplement those which were published in the "B.J.," of October 28, 1921 (page 645), and in the "B.J.," of July 14 last (page 420.) The new specification states that the invention relates to the manufacture of printing plates according to the process described in patent specification, No. 24,607, of 1913 ("B.J.," September 18, 1914, page 714), in which a negative film on a translucent plate is placed in direct contact with the opaque original and exposed through the translucent plate, the image therein being then transferred to the printing plate in the usual manner. When it has been desired to print an edition, from an ordinary litho-press or from a zinc rotary press, it has been necessary to interpose a counter-transfer printing in order to enable the illustrations or letterpress to appear reversed. Owing to this transfer printing and counter-transfer printing, the originals that are to be duplicated lose considerably in sharpness of definition.

The new invention renders it possible to produce negatives in such a manner that they can be used in the production of printing plates without transfer printing, both on the litho-machine plate and the offset press. It consists in a process for the manufacture of negatives from opaque originals, for the purpose of producing printing plates for photo-lithography, according to the British patent specification named (No. 24,607, of 1913), characterised by the feature that the dyed chromate-colloid film is bedded between transparent thin films, one of which allows the negative to be stripped from its support, and the other provides a protective coating. In carrying out the process the chromated colloid film, which has a thickness far below $\frac{1}{1000}$ m.m. is placed upon a plate which is first provided with a coating that will enable the film to be subsequently stripped off. After developing by washing out the unexposed parts and rendering opaque to light the film that has remained on the plate, the film is given a coating of gelatine poured on to its upper side, and after it has been dried, the film is separated from its support. The stripped film or negative is then used for preparing the printing surface.

The following advantages are claimed for the process:—

(1) It is possible to work without printing on to transfer printing paper and subsequent transfer printing on to the offset machine plate. The negative can be copied directly on to the machine plate with the help of the drawn-off negative. (2) By reason of the absence of the glass plate as a film support, it is possible to use the stripped negative right and left for copying, so that it is possible to copy the picture or the reverse picture as desired by means of the machine plate, that is to say, the negative can be used both on the offset printing press and on the direct printing plate or litho-stone.

The method of carrying out the invention is as follows:—Two glass plates are placed one on top of the other with the sides intended to receive the poured on coatings outermost, and they are pressed together by means of clamps. The plates are then dipped with their four edges into a rubber solution, so that a rubber border 0.25 cm. wide, is formed on each plate, and the edge surfaces of the two glass plates are coated with a fine film of rubber. The double plate is then dipped completely into beeswax dissolved in carbon tetrachloride. The double plate is thereby covered with a smooth perfectly clear film of wax. The dried double plate is next dipped into a vessel containing 3 per cent. collodion and a few drops of castor-oil, and placed upright to dry. After the drying the plates are separated, and a solution of chromate colloid poured upon them. The further treatment is the same as that of the simple glass plate having no coating to allow stripping the film negative as described in the patent specification already referred to. After the drying of the negative there is applied to the upper side a poured-on coating of an aqueous solution of gelatine containing a few drops of glycerine. After the pouring on has been effected, the glass plate is placed upon a cold foundation, and the gelatine is caused to dry rapidly. The drying is effected by means of warm air. The nega-

tives may be retouched in the dry state unless it is preferred to do the retouching on the metal plate. Then the film is cut through along the rubber borders, and the negative is drawn-off the glass plate and then cut to the proper size.

The following patents have been applied for :—

OFFSET PRINTING.—No. 20,698. Process for making printing plates for offset or lithographic printing, etc. C. Winkler.

COPYING PROCESS.—No. 20,699. Copying process for making printing plates. C. Winkler.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, July 24 to 29 :—

PRINTING APPARATUS.—No. 20,191. Photographic printing apparatus. H. R. Eason.

FILMS.—No. 20,373. Photographic films. E. C. V. Miller.

TELESCOPIC ATTACHMENTS.—No. 20,542. Telescopic attachments for hand-cameras. A. Warmisham.

STEREOSCOPY.—No. 20,346. Means for obtaining stereoscopic pictures. E. H. Wright.

CINEMATOGRAPHY.—No. 20,444. Manufacture of non-inflammable films for cinematographs, etc. F. G. Edbrook and F. Edwards.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

FILM DEVELOPING APPARATUS.—No. 154,212 (November 22, 1920).—A rectangular vessel 1 is subdivided by one or more partitions such as 2 to form separate receptacles 3—4 to contain respectively developing solution and water, and if desired an additional receptacle may be provided so that the film may be passed through two developing solutions of different strengths.

At opposite ends of the tank near the top means are provided for conveniently attaching for rotation the film spool 5 and the transfer spool 6.

A short stud 7 is fixed on the wall and engages the usual axial recess 8 in one end of the spool whilst the other end of the spool is attached to the end of a crank shaft 9 which

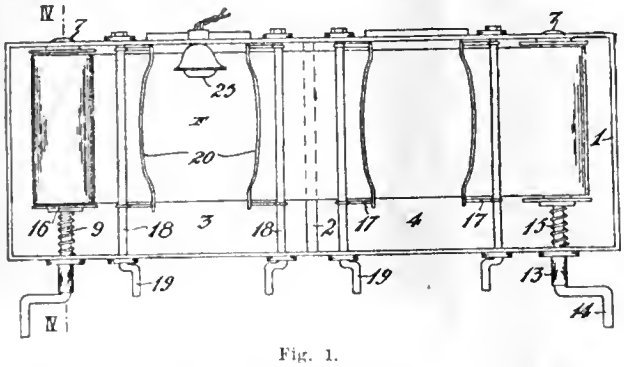

Fig. 1.

enters the axial recess 10 of the spool and is provided with a transverse pin 11 the projecting ends of which engage end recesses 12 formed in the end of the spool. The shaft 9 extends through the wall of the tank and a bearing sleeve 13 thereon and is provided with means to rotate the shaft such as a crank handle 14. A spring 15 is wrapped on the portion of the shaft between the tank wall and a washer 16 at the inner end of the shaft which maintains the connection of the spool with the shaft.

In order to release the spool the latter is moved endwise against the pressure of the spring to free first the stud 7 and then the inner end of the crank shaft and by reverse action the spool is rotatably fitted in the tank.

The end of the wrapper attached to the film spool 5 is passed along the tank and its end is attached to the transfer spool 6, means being provided for insuring the film F as it

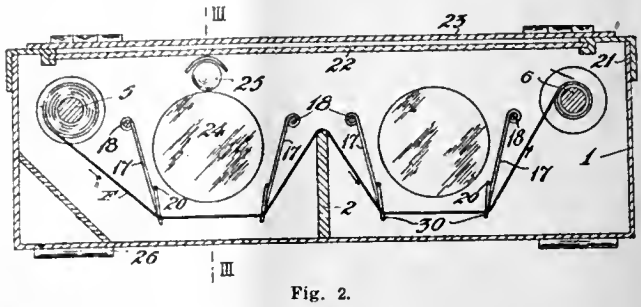

Fig. 2.

is drawn from spool 5 to spool 6 being immersed in the liquid in the receptacles.

The means for immersing consist of arms 17 arranged in pairs on shafts 18, one pair to a shaft. Each shaft is rotatably mounted in the side walls of the tank, one end of the shaft projecting through the wall and bent to form a crank handle 19

The arms bear upon the side edges of the film and the arms of each immerser may be connected by a curved bridge piece 20. The arms and bridge piece may be formed of a suitably bent single length of wire the ends of which are

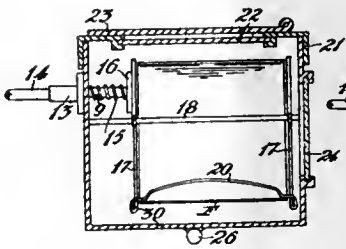

Fig. 3.

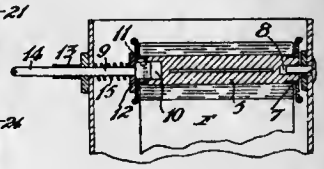

Fig. 4.

fixed to the shaft 18 whilst the downwardly projecting loops 30 act as guides for the film. It will be understood that by turning the crank arms a portion of the film, *i.e.* a single negative, may be pressed down till fully immersed in the developing solution or the water.

The cover of the tank may be a ruby tinted glass slide fitting guideways on the top edge of the tank, or a flanged metal cover 21 may fit over the tank, the cover having a ruby glass panel 22 and being provided with a hinged lid 23.

One side of the tank may be provided with a ruby tinted glass panel 24 to admit light on the negative in each receptacle so that by looking down through the transparent panel 22 of the cover the progress of development of each negative in succession may be observed.

Instead of the transparent side panels an electric ruby tinted lamp 25 may be provided on the interior side of the tank wall as shown in figs. 1 and 2. Henry Charles Frank Morant, Monbuek, Riversdale Road, Hawthorn, Victoria, Australia

SELF-PORTRAIT SHUTTER RELEASES.—No. 167,898. (June 1, 1920). The camera, which may be of any ordinary type indicated at 10, is provided with the usual flexible tube 11 having a bulb for controlling the operation of the shutter, but in lieu of such a bulb the apparatus includes a cylinder 12 which is in communication, by means of a nipple 13, with the tube. A reservoir 14 having a nipple 14^a, with which may be connected an ordinary bicycle pump for producing pressure within the reservoir, is in communication by means of a tube 16 with a pressure chamber 17, the communication being controlled by a valve 18 which is yieldingly held seated by means of a spring

19. This valve is carried by a lever 20 provided with an armature 21 arranged in relation with an electric-maguet 22, in circuit with a battery 23 controlled by a switch such as of the push button type indicated at 24, any suitable length of connection 25 being arranged between the switch and the battery and magnet, which are preferably arranged in a small compact space.

Within the cylinder 12, which is in communication with the pressure chamber 17, is a piston 27 yieldingly held in a repressed position by an actuating spring 28 which is compressed to cause a discharge of air from the upper portion of the cylinder to the shutter actuating means through the tube 11 by an

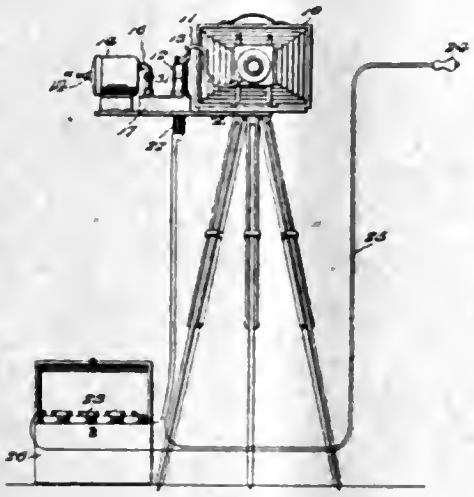

Fig. 1.

increase of pressure in the chamber 17 sufficient to move the piston in opposition to the spring 28.

The reservoir being charged with a suitable pressure of air, and the several connections having been made, the closing of the circuit through the battery and magnet by the operation of the switch 24 will cause the attraction of the armature 21 and the unseating of the valve 18, which, admitting pressure to the chamber 17, will result in the actuation of the piston and the discharge from the upper end of the cylinder 12 of a sufficient

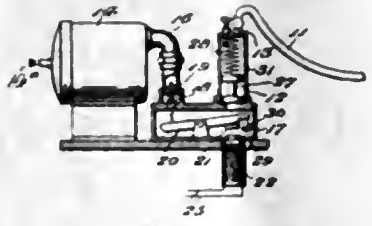

Fig. 2

quantity of air to actuate the camera shutter. If a snapshot is to be taken it is simply necessary to momentarily close the circuit and then permit it immediately to open, whereupon the pressure within the chamber 17 will escape through the outlet 29 and the spring 28 will restore the piston to its normal position and permit the camera shutter to close. On the other hand, if a time exposure of any desired duration is required, it is simply necessary to maintain a closed circuit through the magnet for the required length of time, the lever 20 being provided with a closure 30 for the outlet 29 when the armature is in its attracted position and the valve 18 is open.—Hans Benjamin Emmrich, Giddings, Lee County, Texas, U.S.

The following complete specifications are open to public inspection before acceptance:—

Apparatus.—No. 183,441. Optical apparatus for reflecting still or animated photographic images. C. van Soolen.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Lumograph.—No. 426,511. Pictures, photographs and printed matter included in class 39. Harold Bernardo Molins, 2, Evelyn Street, Deptford, London, S.E.8, manufacturer. May 25, 1922.

MARKS PLACED ON THE REGISTER.

The following marks have been placed on the register:—

Iconta.—No. 423,292. Optical, photographic, cinematographic, and projection apparatus included in class 8. Ica Actiengesellschaft 72-80, Schandauerstrasse, Dresden, Germany, manufacturers.

EDINBURGH SOCIETY OF PROFESSIONAL PHOTOGRAPHERS.

Meeting held at 116, Hanover Street, Edinburgh, on July 28. Present: Miss Grace D'Arcy, Messrs. J. Campbell Harper, George Balmain, A. Swan Watson, J. C. Bambrick, and E. D. Young. Mr. J. Campbell Harper, President, in the chair.

The Secretary read a letter from Mr. Harold Hood, of Middlesbrough, thanking the Society for sending a copy of its rules, and saying that he hoped to made good use of them in forming a similar Society for the North-Eastern District of England.

The President reported that he had called on Mr. McNally, of the Education Department, with regard to securing a teacher in place of Mr. Hislop, for the optics and practical chemistry class. Mr. McNally stated that he had no one in view, but that he would make every endeavour to secure the appointment of a trained teacher before the beginning of the session.

The secretary read a letter dated May 25, 1922, which he had received from the Secretary of the Glasgow and West of Scotland Society of Professional Photographers. He stated that he had consulted with the President on the terms of the letter, and had replied that without discussion the boundary line proposed appeared to be satisfactory, but that it must be left to the country photographers themselves to choose which Society they wish to join. This was approved of by the meeting, and it was resolved to allow the matter to be over until the next meeting.

The Secretary reported the response which he had received to his circular letters addressed to the photographic dealers and manufacturers inviting them to take stalls at the proposed forthcoming congress and fair. As the support promised from the trade was so unsatisfactory, the Society did not feel justified in holding the Fair. It was, accordingly, resolved not to proceed with the proposed congress and fair in March next, but that the Society should consider at its next meeting whether a congress and exhibition should not be held instead. The Secretary was instructed to notify those members of the trade who had agreed to take stalls, and also those

who were at present considering the matter, and thank them for their support and co-operation.

Mr. Young drew attention to a statement in this month's "P.P.A. Record," and also on the back of the P.P.A. Membership Card, where it is stated that this Society was affiliated to the P.P.A. The Secretary was instructed to write the Secretary of the P.P.A. and point out that such is not the case, and that the statement must have been made under a misapprehension.

A vote of thanks to the Chairman concluded the business.

Commercial & Legal Intelligence.

NEW COMPANIES.

YVONNES (LEEDS), LTD.—Private company. Registered July 27, with a capital of £700 in £1 shares. Objects: To carry on the business of photographers, lithographers, artists, picture dealers, manufacturers of and dealers in photographs, engravings, etc. The first directors are: H. Warrillow, British Queen Inn, Hunslet, Leeds; Miss W. M. Warrillow, British Queen Inn, Hunslet, Leeds; Miss F. G. Warrillow, British Queen Inn, Hunslet, Leeds. Registered office: 24, Albion Place, Leeds.

LIVINGSTONE ART CO., LTD.—Private company. Registered July 25, with a capital of £5,000 in £1 shares. Objects: To carry on the business of photograph enlargers and photographers, picture framers and importers, makers, sellers and dealers in pictures and picture frames and mounts, artists' colours, oils, paints and brushes, etc. The subscribers (each with one share) are: L. G. Howes, 90, Estcourt Road, Woodside, Surrey, secretary; W. W. Watling, 160, Crofton Park Road, Brockley, S.E.4, solicitor's clerk. W. R. Livingston is permanent managing director. Registered office: Sentinel House, Southampton Row, W.C.

News and Notes.

OWING to the Hampshire House (Hammersmith) Photographic Society's rooms being destroyed by fire, it has been necessary to make other arrangements and to change the day of meeting to Tuesday of each week, *pro tem.*

IRISH SALON OF PHOTOGRAPHY.—The Executive Committee of the Irish Salon of Photography announce that, owing to the disturbed condition of the country, they have, with great regret, decided to postpone, until further notice, their first exhibition, which was to have been held in August.

A NOVEL SUBJECT.—Probably the most-photographed man in London last week was one who cut the grass in Parliament Square with a scythe. The old-fashioned tool looked strangely out of its element, and many scores of amateur photographers, as well as several Press workers, seized the opportunity of making exposures on what was truly a novel subject.

A WITCH DOCTOR'S PHOTOGRAPH.—An interesting photograph of a witch doctor was reproduced in the "Daily Telegraph" of the 2nd inst. This extraordinary photograph was obtained with difficulty by a party of English explorers on a journey from the Zambesi to Khartoum. Witch doctors, or mystery men, in common with many Central Africans, have a great dislike to the camera, but the individual pictured was induced to pose in full regalia, with his stock-in-trade arranged for consultation.

P.P.A. CONGRESS NOTE.—The Council of the Professional Photographers' Association of Great Britain and Ireland, Ltd., desire to remind all members that it is imperative they should bring their membership cards with them to the Congress, as the cards must be shown on all occasions when requested. Members who have not paid their subscription for 1922-23, and are not in possession of their membership card, are not entitled to vote at the annual general meeting, or to have free admission to the Congress, lectures or excursions. Members who desire to bring a professional friend to the Congress can obtain from the secretary, Mr. Alfred Ellis, a special card (price five shillings), giving all the privileges of membership during the Congress week.

A COURT PHOTOGRAPHER is reported by the "Evening News" to have said: "Every woman, old as well as young, should come to be photographed wearing a dress of light colour. If pince-nez or spectacles are usually worn, they should not be taken off for the photograph." "Does this apply to huge, round, tortoiseshell goggles?" he was asked. "Ah," was his reply, "I'd better make those the exception to the rule. For they are often worn as a fashion, not quite as a necessity. I'm afraid they would not add to the beauty of the photograph."

MR. PIRIE MACDONALD.—We clip the following paragraph from "Abel's Photographic Weekly": Mr. MacDonald is going to England in the fall as official delegate from the P. A. of A. to the British Congress of the Professional Photographers' Association of Great Britain and Ireland, and will present a silk U. S. flag to that Association on that occasion. Mac will then run over to Paris—wager he flies over—and will present a similar flag to the French Photographic Association, or Chambre Syndicale Francaise de la Photographie, as it is officially termed.

AMERICAN ADVERTISING.—"Abel's Photographic Weekly" states that among the photographers' trade cards seen at the Seattle Convention was one used by H. G. Nelson, of Elma, Wash., which had printed upon the back this very apt quotation from Elbert Hubbard:—"Faces fade, and the people we once knew, some of them, are gone for ever. Children grow up and go away. The old house is torn down. The pets die or disappear. The time to take the picture is when you see it. The historic value of things, fixed in the form of a photograph, is beyond price."

THE PARAGON CAMERA IN TIBET.—Messrs. W. Butcher and Sons, Ltd., received by last week's mail from Tibet a very interesting photograph and letter from Capt. J. Noel, the official photographer to the 1922 Mount Everest Expedition. The letter, which was written on May 5 at the Main Base Camp, Rongbuk Glacier, Tibet, reads as follows:—"Dear Sirs,—I have pleasure in telling you your Paragon camera is serving good use with the Mount Everest Expedition It is an excellent camera for the simplicity yet completeness of its controls and movements. I find the lens turret and back control panel very special features. I enclose you a photograph of the camera and myself at the Base Camp of the Expedition below Mount Everest at 17,000 feet, on the Rongbuk Glacier, and I hope you will like the photograph.—Yours faithfully, J. NOEL."

THE IMPERIAL HANDBOOK FOR 1922 has reached us, and a very beautiful production it is. It is as full of useful information as the proverbial egg is of meat, while the illustrations are far above the average. It is close on thirty years since the first Imperial Handbook was published, and every year, without a break, the booklet has made its appearance, each issue being eagerly seized upon and perused by all classes of photographers. The 1922 production contains many well written articles dealing with the firm's roll-films, "D.S." backing, and other specialties, also special illustrated articles on "Record Work," "Studio Lighting Out of Doors," "Process Plates for Ordinary Work," "Byways in an Old Town," "Panchromatic Plates," and "Photography in Lamplight." Copies may be had gratis from dealers, or direct from the Imperial Dry Plate Co., Ltd., Cricklewood, London, N.W.2.

BEACH PHOTOGRAPHERS' BAD SEASON.—A photographer who has a stand on the sands at one of the most popular South Coast health resorts, writes as follows: "The paragraph in the "B.J." telling of our bad luck this season, mainly because of the inclement weather, is only too true, but we live in hopes for a good August and a better September, so that we may make good our losses, but it has been a difficult matter for us and our few sitters to 'look pleasant' when high winds and drizzle were about. July was one of the wettest summer months on record. The rainfall during the month was nearly an inch and a half above the normal. As a contrast to the sunny July of last year, there were only 140 hours of sunshine, compared with 257 in 1921 and the normal 201. The total rainfall during the month was nearly four inches. It was a dull month all round. Depressions converged on us from all directions. An average of 4.5 sunny hours a day in July is quite exceptional, and it was the wettest July for years."

THE CAMERA AND THE CUSTOMS.—Many photographers have been led to believe that a man who takes a foreign-made camera to the Continent may be faced with a demand for Customs duties on his return to England. This is an error (says the "Daily News").

The Board of Customs in their reply dated July 24 to a query from us to say that "it is their practice to waive payment of duty in the case of a camera imported by the owner on his person or in his luggage, if properly declared and produced to an officer of this Department examining baggage, provided the officer is satisfied that the article has been in the passenger's private use for a substantial period. An oral declaration of ownership is usually accepted, but if the camera shows no material sign of use a declaration is required on Form 104." Form 104 is the ordinary Customs form for an Owner's Declaration in respect of personal baggage, and when used to cover the return to England of a camera which the owner took out with him, it merely requires him to declare that he actually took it out of the United Kingdom on the date of his departure.

PHOTOGRAPHIC ANALYSIS OF MOVEMENT.—Particular attention is now being paid to "slow-motion" photography, and many interesting examples are being exhibited. A writer in the "Star" states that Mr. W. Pycraft, F.Z.S., has been able to prove a theory that he has long held, but which he could not prove. This is that the air is an "ocean," or "sea" for birds, used by them in the same way as the sea is used by fish. Slow-motion pictures taken of a bird in flight, a fish swimming, and a turtle's flippers in motion, show that all the movements are similar. Ordinary film negative contains 16 pictures to the foot, and the ordinary cinematograph camera, it is pointed out, "takes" at the rate of a foot a second. The ultra-rapid camera for slow-motion pictures takes at 250 pictures a second (or about 15½ feet). The result is that a motion which would be shown in 16 pictures of ordinary film, needs 250 pictures of the ultra-rapid camera to show it. Each particular motion thus slowed down can be minutely analysed and studied. The writer also mentions Mr. Bruce Woolfe, who has taken slow-motion photographs at the Zoo of a kangaroo jumping and of a seal diving. Another picture is of a toad eating. Toads eat by darting out a tongue and drawing in insects, etc., on it. Each dart takes about a sixteenth of a second, so that by the ordinary film camera one picture goes to each dart, and all one can see is a slight blur on the negative. With the special camera every movement of this tongue can be distinctly followed. So also is it with a snake's fangs. To watch the forked tongue with the ordinary eye one would think that this darting is an indiscriminate waggle. The camera shows that this forked tongue always moves the same way. Scientists before had suspected many of these things. They could never prove them.

THE "FREE-SITTING" AGAIN.

To the Editors.

Gentlemen,—As a regular subscriber to the "B.J." for many years I have read of the attacks that have been made upon the free-sitting photographers, including, of course, your recent note ("B.J.," June 23), and one later referring to it ("B.J.," July 28), and as far as I can understand none of the free-sitting photographers has had the courage to pen a line in defence of his methods; all appear to have taken the attacks "lying down," and to have gone on as usual in their own sweet way.

I am interested more in the scientific than in the professional side of photography, and as a looker-on I claim to be able to see most of the game as it is played by professionals, and I must confess that I have a great deal of admiration and sympathy for the free portrait man, who has plenty of initiative, an unbounded faith in human nature, and does not mind speculating: "Faint heart never won fair lady" being his motto.

Even the greatest opponents to the free-sitting I believe admit that it is in certain cases a perfectly legitimate plan of working. What professional worker would object to give Miss Ethel M. Dell a free-sitting? Not one. Her portrait was, and still is, in great demand, but it does not exist, and he will be a lucky worker who first secures one. There are, of course, many other celebrities who have never been photographed, but I mention Miss Dell because of the lady being at the moment in the public eye. If this point be granted—as I feel sure it will be—then where are we to draw the dividing line between what you state to be the legitimate and the illegitimate? Here is the difficulty, and the free-sitting game has got into disrepute because some photographers are said to have overstepped the mark.

There must be differences of opinion as to who is and who is not a celebrity, and a man may go to bed at night a nonentity, only to awake in the morning to find himself famous—or, at any rate, a suitable subject for the illustrated papers. I need not, however, labour this point, as there is a stronger one in favour of the free-sitting man.

The strong point in his favour is speculation, and there is so much and so many against him that it is difficult to believe that he can win, but I suppose he does at times, otherwise the free-sitting would become a thing of the past. Much money must be spent in circularising likely people, and the making of the pictures must give work to several hands—who, I suppose, have to be paid—and all this is done on the chance of getting an order. I often wonder what the percentage of orders really is, and judging from the comments I have heard from those who have accepted free portraits I should say it is exceptionally small. But does the free-sitting man worry his clientèle if no orders come along? I do not think so. He writes off the sales to the sitters, and waits for the demands of the Press for which the portraits were taken. If there is no demand then the photographer has speculated unwisely and loses, but we hear of no grumbling because he has only himself to blame. What grumbles are heard come from those professionals who failed to speculate, doing business only when called upon to do so. If then there be no demand from the Press, or from the sitter himself, for copies, no harm is done to brother photographers who carry on business in the orthodox manner.

People who really want their photographs taken usually go to a studio and pay for them, and they do so, as a rule, before the free-sitting man reaches them.—Yours faithfully,

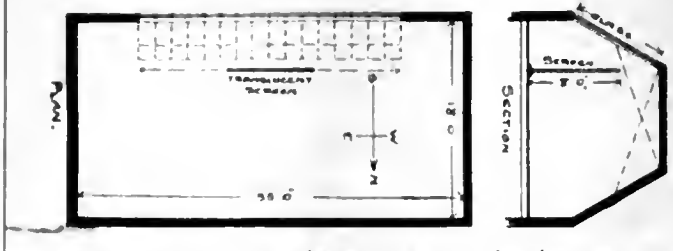
London, N. H. M. ROBINSON.

A SOUTH LIGHT.

To the Editors.

Gentlemen,—Apropos your Editorial note on the above, in the issue of the "B.J." dated July 28, may I add that the solution of this problem by the late Valentine Blanchard, which is, I think, still the best way out of the difficulty, is fully described, with plan and section, in my monograph on "The Studio," which forms No. 182 of "The Photo Miniature" (New York: Tennant and Ward).

I am also sending you herewith a diagram of a modification of the idea, of my own design, in which the black solid lines represent the opaque portions of the walls and roof of a single slant studio, the shaded portions of the glass being of rough cast plate and the shaded movable screen of tracing cloth or other translucent



material. As in Mr. Blanchard's studio, "The sitter cannot see the side of the screen on which the sun's rays fall, so that there is no sunlight to dazzle the eyes, and as the sun travels westward the screen can be drawn to the east, to give more light if necessary; while working with the sitter at either end of the studio the screen can be moved about according to the time of day, and yet give the sitter all the light required."

Anyone who will try an arrangement like this in a south lit studio will find that, in addition to being able to cut down exposures, he will be able to obtain many luminous yet delicate effects that are difficult, if not impossible, under other conditions.—Yours faithfully,

DRINKWATER BUTT, F.R.P.S.

2, Margravine Studios, Baron's Court, W.6.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

L.A.—We have not heard of the Photo Autocopyist Company for a long time and do not know whether the business is still being carried on. They were formerly, as you say, at 64, Queen Victoria Street, E.C. Messrs. A. W. Penrose and Co., 109, Farringdon Road, London, E.C.1, have, or had, a somewhat similar process. It might be worth while to write to them.

H. C.—If you do not use direct light we think that a saturated solution of potassium bichromate is reasonably safe for use with ordinary plates; that is to say, if the lamp is arranged on a wide shelf above the working bench, so that all dishes, plates, etc., are in the shadow of the shelf. But in order to make the light safe for the exposure of plates to direct rays, it is necessary to add dye to it, e.g., rose bengal or fast red. It is not very satisfactory to use this mixture, because the dye is gradually oxidised by the bichromate, and, in fact, we are rather at a loss to understand what particular advantage you expect to gain by using this rather cumbrous method of immersing a bulb in a coloured solution. We think one or other of the ordinary types of lamp working by reflected light is very much better.

F. S.—Three focus means that the front and rear glasses of the complete lens are of different focal lengths, so that altogether you get three focal lengths. Usually one of these is double the focal length of the complete lens and the other one about one and a-half times the focus of the whole lens. We should imagine that the lens is some kind of anastigmat, but the description is not enough for us to say. Apparently the diaphragms are marked according to the U.S. or Uniform System, much used in America, but it is rather strange that the full aperture is U.S.8, which is equivalent to f/11.3. It almost looks as though the lens had been tampered with in some way, and the fact that it does not give sharp focus when focussed sharply on the ground glass seems in accordance with this.

C. H. K.—(1) The following is a formula recommended by the makers of metol :—

Water (distilled)	20 ozs.
Metol	130 grs.

Dissolve the metol and then dissolve in the order given.

Soda sulphite cryst.	3 ozs.
Potass. carbonate	1½ ,,
Potass. bromide	18 grs.

This stock solution keeps well; for normal exposures, it is mixed with three to four times its bulk of water; for over-exposures, with about twice its bulk of water; and for under-exposures, with about six times. For over-exposures where increase of contrast is required, add 10 per cent. potass. bromide solution. (2) We think you can obtain match-boxes with any required design on them from the Glossoid Co., 8, Mason's Avenue, London, E.C.2.

C. M.—Optical goods (including cameras) brought into this country from Germany pay a duty of 33⅓ per cent., in addition to the reparations duty of 26 per cent., which has to be paid to the German authorities before goods may be taken out of Germany. We understand that a very strict examination is made of passengers' luggage, both at the German frontier and when re-entering England, in respect to optical and photographic goods. We do not think for a moment that the fact that the camera has been used personally between the time of its purchase and its entry into England will be any ground for exemption of payment of the duty either in Germany or here. Under the Safeguarding of Industries Act the duty is, in fact, levied for the purpose of restricting importations, both retail and wholesale. We daresay that you have seen quoted, during the last few months in the "B.J.," instances where very heavy fines have been inflicted on people who have attempted to smuggle single cameras into the country.

P. H.—We do not know a formula for the true-scale composition which we can recommend, for a somewhat extensive correspondence with engineering photographers, who are using this process, has shown that no composition made up according to formulæ which have been published works nearly as satisfactorily as the compositions bought from a firm such as B. J. Hall & Co., Ltd., Chalfont House, Great Peter Street, Westminster, London, S.W.1. (1) The blue print is kept in contact with the composition for about 15 seconds. (2) We do not think it is practicable to treat the composition so as to prevent parts from printing dirtily. This should be done on the blue print before it is applied, namely, by stopping out such parts by painting them over with thin, quick-drying spirit varnish. No doubt something can be done on the composition itself by carefully sponging with a damp sponge or rag. You will find the best instructions for the working of the process in the manual by B. J. Hall, "Blue Printing and Modern Plan Copying," published by Sir Isaac Pitman & Sons, Parker Street, Kingsway, London, W.C.2, price 6s. net.

P. P. J.—In our issue for May 28, 1915 (page 359), W. Ethelbert Henry published the formula for the white-image developer manufactured and sold for some years past by his firm, the Vanguard Manufacturing Company. On an ordinary gelatino-bromide plate, or dry ferrotype plate, it develops similarly to collodion—both as to image and rapidity of action, the main trouble (to the uninitiated) being to judge when development is complete. The developer is used at full strength, and can be returned to the bottle for repeated use without discolouration. The formula, reduced for users on a small scale, is as follows:—

A.—Dry sodium sulphite	3½ ozs. av.
Hot water to make	16 ozs. fl.
While hot, add—	
Quinol (hydroquinone)	120 grains.
B.—Ammonium chloride	3½ ozs. av.
Ammonium bromide	40 grains.
Hot water to make	16 ozs. fl.
C.—Strongest liquid ammonia	2 ozs. fl.

Add B to A, and then add C. Filter when cold.

The following are the instructions for the use of the developer, which, we believe, is still supplied by the Vanguard Manufacturing Co.:—"The plate must receive a full exposure, and must then be developed with this solution without the addition of any water whatever, the plate must then be fixed in an ordinary clean hypo bath. The developer should be returned to the bottle after use, and it will be found to remain in prefectly good condition for a very long time without the slightest discolouration. When first used, the operator will have some difficulty in noting the appearance and development of the image, owing to the fact that the developer causes a white deposition of metallic silver. It can, however, be followed to some extent by viewing the plate occasionally by looking through it towards the light. After one or two trials, there will be little difficulty of this kind."

SUMMARY.

In a further paper of the series, "With a Portraitist in the Studio," Mr. J. Effel deals in an instructive and entertaining manner with the problem of the bust portrait and also with the three-quarter length picture. (P. 488.)

When every care has been taken in the making and mounting of photographs, deterioration may often take place within a comparatively short time through the bad conditions under which the photograph is kept. In a leading article we refer to some of the chief causes which may give rise to such deterioration after photographs have passed into customers' hands. (P. 486.)

In the second chapter on depth of focus the different senses in which the term "hyperfocal distance" has been used are considered. It is shown how the formula for hyperfocal distance is obtained on the basis of a fixed permissible disc of confusion in the negative and how this formula assumes a simpler shape if the permissible disc of confusion is taken as a certain small fraction of the distance from which a print or enlargement is viewed. These formulæ likewise tell the F. number or actual diameter of stop which is required, according to one view or the other, for a given hyperfocal distance. (P. 492.)

Working details of a novel method of cutting rectangular masks with but one cut of a knife are given on page 487.

Although photographic printing processes are often roughly classed as "permanent," and otherwise, a very great deal depends upon the degree of care which is taken in the making of the print. (P. 486.)

Considerable opportunity for the exercise of judgment in determining exposure is required, even when using a meter, particularly as regards making allowance for the scale of tones, some useful hints regarding which will be found on page 491.

There still seems to be the need for cautioning those sending negatives through the post against the flimsy packings which are still often used. In a paragraph on page 486 we briefly describe the form of packing which can be relied upon to ensure the safe transit of negatives.

Vest-pocket negatives which are to be enlarged upon a considerable scale call for more than ordinary preparation in the shape of retouching of defects on the film side and elimination of scratches on the glass side. (P. 485.)

For several reasons no useful purpose is served, in our opinion, by prescribing any particular quantity of hypo as sufficient for the fixation of such and such a number of prints. (P. 485.)

The desirability of a British Empire Patent was one of the problems discussed at a recent Government conference. A scheme was put forward for the establishment of a central office. (P. 499.)

EX CATHEDRA.

Scratched V.P Negatives. Despite the great efficiency of cameras of the vest-pocket size as regards obtaining sharply focussed pictures, the user of them, who comes to making enlargements from the little negatives, encounters difficulties due, not only to minute imperfections from dust, etc., on the emulsion film, but also to scratches on the glass side. For the former, perhaps the best plan is to coat the whole surface with retouching varnish and to go over the negative, with the aid of a magnifier, with a retouching pencil. As regards the glass side, owing to the thinness of the glass generally used for vest-pocket plates, scratches will very frequently show in the enlargement. They can, however, be eliminated by cementing a clean glass plate to the negative with Canada balsam. Negative and glass should be well warmed, a drop of balsam put on the back of the negative, the cover glass carefully brought into position, and pressed down so as to drive out air-bells. The two glasses then require to be held under firm pressure, as can conveniently be done by means of an ordinary lantern-slide binding clamp, for the balsam to set and harden. While under this pressure the glasses should be brought to a moderately high temperature in front of a fire or in an oven.

* * *

Hypo for x Prints. Every now and again we are asked by correspondents to tell them the quantity of hypo which should be allowed for the fixation of so many prints. While economy in the use of chemicals is not to be deprecated, stinting of the fixing bath is, we think, the worst form which such economy can take. Moreover, we do not think it is possible to name a quantity of hypo sufficing for the proper fixation of a given number of prints, since the conditions under which the fixing bath is used vary so greatly. It is true that in the past several people have prescribed the quantity of hypo for a given area of paper. MM. Lumière did so some years ago, and an American professional has recorded his experience of using hypo in the proportion of one ounce per 330 square inches of paper. But such figures are not applicable with safety to regular commercial conditions, for in arriving at them more than customary care is taken to ensure each separate print being fully exposed to the action of the fixing bath, whereas, in commercial practice, such is often far from being the case. Further, papers vary in the proportion of silver salt which they contain and also the temperature factor considerably affects the useful work which a given bulk of hypo solution will do. And if these causes of variation were not enough, there is a further one which is often overlooked altogether. This is the continuous dilution of the hypo solution which goes on by the introduction of prints undrained from the developing solution or wash bath and the corresponding abstrac-

tion of hypo by removal of prints with a goodly proportion of fixing bath adhering to them. From both these causes the strength of the fixer may be very substantially reduced without the user realising the fact. On all these accounts there is only one good rule for practice, namely, to use plenty of hypo and preferably to pass prints through two fixing baths in succession. In the making of prints which command a fair price the cost of a triple or quadruple quantity of hypo above that which is theoretically necessary is insignificant.

* * *

Packing Negatives. It might perhaps be thought that photographers for generations have been sending glass negatives through the post with such frequency that secure packing had become a question of instinct. Yet it is our experience and, we believe, also that of the enlarging firms, that negatives are very frequently dispatched with the most inadequate protection against the operators of the defacing stamps in the postal sorting offices. Anybody who has occasion to send a negative by post ought to try to realise the hammer blows to which parcels are subjected on the tables of a postal depôt. Against these destructive efforts, there is only one kind of effective measure, and that is to shelter the negative in a rigid casing, the outside walls of which will take the shock of the defacing stamp. A cardboard box, such as that in which plates are supplied, if wrapped in a few layers of corrugated paper, will no doubt afford sufficient protection in nine cases out of ten, but in the tenth instance the negative, even when carefully packed in this manner, may be broken in transit. On the other hand, it may be taken as reasonably certain that a negative packed in a wooden box with a resilient flat packing, such as corrugated paper, above and below it, is in a condition to defy the postal officers to do their worst. Corrugated paper is better for this purpose than crumpled newspaper, since it affords a flat elastic bed for the negative, and does not provide the occasion for local strain on a sudden shock to the whole box. Cotton-wool or fine wood shavings are probably as efficient. If several negatives of different sizes are being sent together in one box, care should be taken to place all those of a size together, so as to prevent the smaller from bearing unevenly on the larger. The two lots should, moreover, be separated by one or other of the kinds of packing we have just mentioned.

* * *

Permanency When we are asked to say whether the prints on such and such a paper or by a given process of toning are permanent, we are inclined to take a leaf out of the book of a butler in one of the plays of Mr. Henry Arthur Jones. The butler was pressed by a suspicious husband to swear the truth of what he had said about her ladyship's movements. He discreetly replied that he had spoken "the absolute truth in the circumstances." The application of which is that permanence is a quality of photographs which can only be described relatively, that is to say, in relation to the care taken in the working of the process, in relation to the conditions under which the print is kept and to other factors. Assuming that the respective processes are worked in the best manner, one may group them for permanency according to a schedule which includes a range from carbon and platinum, through development prints with and without toning, to the print-out and self-toning papers. Probably nothing short of wilful destruction is capable of destroying the image on a carbon or platinum print. There was the instance some years ago of a platinotype print having been recovered intact and practically as good as when made from a sunken vessel where it had lain immersed in sea water for several months. The permanency of development and P.O.P. prints, on the other hand, is more largely dependent upon the care taken in making them. Although theoretically a developed silver image is less subject to chemical alteration than one which is printed-out and toned, we would not be prepared to say that the bromide prints of one photographer are more permanent than the P.O.P.'s of another. In fact, we could point to many cases where bromide prints have shown disfiguring markings after a few months, and to others where P.O.P.'s have retained their freshness for years.

THE CARE OF PHOTOGRAPHS.

Considering the very large proportion of portrait photographs which are now made on emulsion development papers, it is a matter of some regret that photographers should not employ more persuasion than we think many of them do at the present time towards ensuring the preservation under the most favourable conditions of the prints which they supply to their customers. The fact cannot be disregarded that the silver image of a development print is bound to suffer a certain amount of change within a few years unless means are taken to delay the processes which give rise to that change. Inasmuch as prints suffer by constant exposure to the air of rooms where gas or stoves are burning, producing slowly a partial sulphurisation of the silver image, the first step in the preservation of photographs is to protect them, as far as possible, from the action of the air. The second measure consists in keeping them in as dry a condition as possible, since any action of the minute quantities of sulphur compounds in the air is accelerated by a moist condition of the prints. A conjunction of both unfavourable conditions may give rise to marked deterioration of prints within a comparatively short time, the original brightness of the photograph being defaced by a species of bloom of semi-metallic appearance. In some cases, which apparently are not as infrequent as might be thought, photographs exposed in an unprotected state on damp walls have actually suffered disaster by being eaten into white patches by insects. The protection against these causes of deterioration is proper framing of the print before it leaves the photographer's hands.

Quite apart from the considerations of tasteful presentation of his work, or of the profit from the supply of frames, there is every reason for the photographer to prevent his work being framed in accordance with the method which is largely followed by the cheaper class of picture framers. The latter cannot be expected to take the care which a photograph from its nature requires. It is rare to find that any steps are taken to exclude air, and very frequently the backing board and the brown paper covering for the back of the frame are put in practically saturated with moisture, so that conditions are made as favourable as possible at the very start for any deterioration to which the photograph may be liable. It is scarcely necessary to point out that the glass should be secured to the rebate of the frame by means of strips of paper, so as to prevent the access of dust and air. In like manner the jointed backboard should be sealed into the frame by gummed strips, so that the picture is in practically an air-tight case, and these paper junctions should be given every opportunity to become dry before the final paper backing is applied. It is an excellent plan, whenever possible, to bind the picture and glass together in passe-partout fashion before insertion in the frame. For the backing, a sheet of stout

manilla paper may be fastened with good glue, and may be caused to stretch taut by a very moderate degree of damping. A further precaution against the access of this moisture to the contents of the frame is to lay a sheet of waterproof paper upon the backboard before applying the final brown paper covering.

The principles which apply to ordinary framing require to be observed equally for miniatures which are put into lockets or rims. Here again air and moisture need to be excluded, by sealing the miniature within its rim with strips of goldbeater's skin, as was invariably the practice in the old days. If goldbeater's skin is not readily obtainable, although most chemists keep it, the thin paper sold in rolls for mending books and music will answer nearly as well for all but the smaller sizes. While we are upon this subject of the delivery of work in the best conditions for permanence, we may add a word on the treatment of originals sent to a studio for copying. These, to say the least, should invariably be replaced with every care for their future preservation, when it has been necessary to remove from a frame or detach from a cover glass, yet it has been our experience to find old and valued portraits put back into their frames or cases with the edges unbound and thus exposed to more deterioration in a few months than they had previously undergone in years.

MASK CUTTING SIMPLIFIED.

[The following is the text of a paper read at a recent meeting of the Croydon Camera Club, where it was accompanied by a demonstration. The Society's reporter described the method as an "ingenious stunt," as indeed it is, and illustrated working details will, no doubt, be welcomed by all cutters of rectangular masks.]

In the masking of prints and lantern slides, rectangular masks of a specific size of opening are frequently required; but the accurate marking off and cutting of such masks (with clean, sharp corners) is a task which is often found to be both difficult and irksome.

By the application of the simple paper-folding method described below, it becomes, however, a comparatively simple operation to mark off and cut a rectangular mask of any

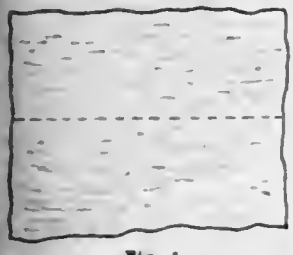

Fig. 1.

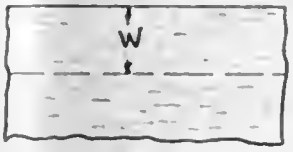

Fig. 2.

given size of opening in less than a minute, and by a single stroke of the knife.

The method can best be described in stages, illustrated by diagrams, as follows:—

1. Take a piece of paper of suitable size and fold it along the dotted line, fig. 1.

2. Rule a fine line parallel with the folded edge at a distance W, equal to half the width of opening required, fig. 2.

3. Turn over the paper and rule two lines at right angles to the folded edge and distance D apart, this distance being the difference between the length and width of the opening required, fig. 3.

4. Fold over the paper as shown in fig. 4, so that the two

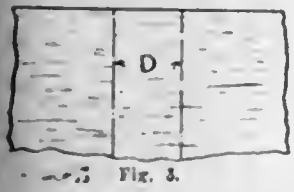

Fig. 3.

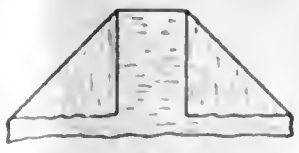

Fig. 4.

portions of the previously folded edge coincide exactly with the lines drawn as in fig. 3.

5. Reverse the now twice folded paper showing again the line ruled as in fig 2, and then cut along this line with a sharp knife against a straight edge X, as shown in fig. 5. A guillotine will, of course, be preferable if at hand.

6. Now unfold the paper and the result will be a mask as in fig. 6, in which the dotted lines show where the folds in the paper occurred.

In the case of either negatives or slides the mask can be readily attached to the film side by a touch of secotine

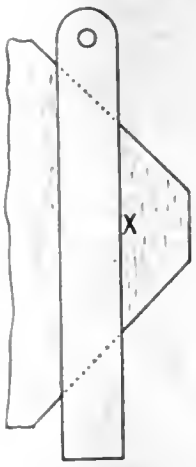

Fig. 5.

diluted with water, and the surplus paper trimmed off afterwards.

If, however, an equal margin of mask is required all around

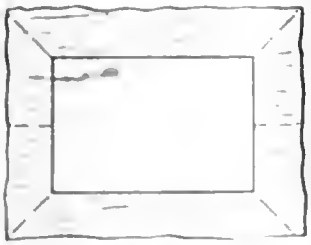

Fig. 6.

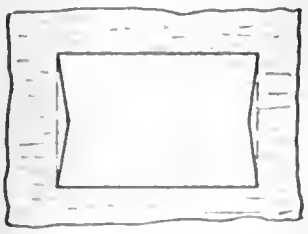

Fig. 7.

the opening it is only necessary to make a second cut with the knife after operation No. 5, leaving the width equal to the actual margin required.

The only risk of inaccuracy in that method of mask cutting lies in the folding over at right angles in operation No. 4; unless this is done carefully the ends of the rectangle will not be quite straight. If, however, care is taken never to

fold the paper too far over, an error will result as shown in fig. 7 (exaggerated for purposes of illustration), which can be quickly rectified by cutting along the dotted lines. This error is only likely to occur in large masks, and even if the adjustment is sometimes necessary the resulting time-saving is still considerable.

To facilitate the marking of the right-angle lines a set square will be found convenient, or failing this, the simple device of a piece of thick paper with one straight edge and folded accurately along this edge, thus forming a true right

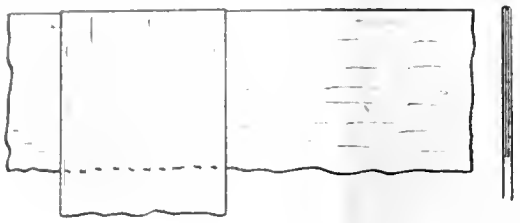

Fig. 8.

angle. In this case the mask to be marked off may be placed between the fold as shown in fig. 8.

The operation of marking off the width line in fig. 2 can be facilitated by the use of a simple rule gauge shown in fig. 9, in which the distances from the rule edge to the steps are marked at twice their actual distances, thus giving a direct measure for the width of mask. Accuracy in the making of such a gauge, using a piece of stout paper, can be ensured by folding it double and cutting both sets of steps at once. This folded gauge can then be used in place of the folded paper shown in fig. 8. The gauge shown in fig. 9 is of suitable proportions for lantern slide masks, the steps being actually 1-16 inch each.

In conclusion, it may be mentioned that this method of

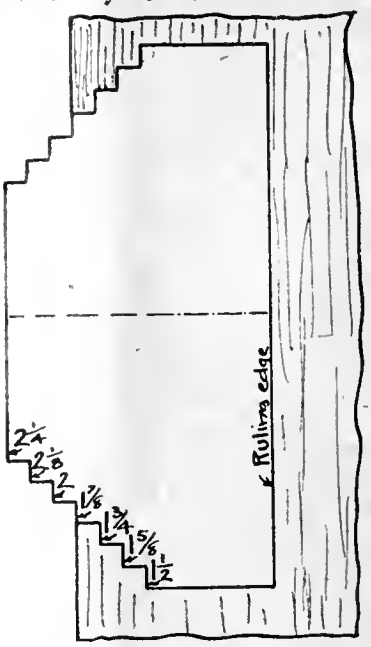

Fig. 9.

cutting masks works quite well with paper of any thickness up to that of fairly stiff drawing paper.

VIVIAN JOBLING.

WITH A PORTRAITIST IN THE STUDIO.

IV.—THE BUST PORTRAIT AGAIN.

[The previous papers of the present series by Mr. J. Effel have dealt (I) with the bust portrait and (2) with the point of view respectively in the "British Journal" of August 4 and August 11 last. In the present paper, Mr. Effel returns to the subject of the bust, and also deals with the three-quarter length portrait.]

I'm glad, George, that you have read that little paper of mine on "the point of view," and that you would like me to go over it in the studio. I think the usual way of leaving an assistant to fill in plates, change backgrounds, and stand about when pictures are being made, without telling him the reason for everything does him little good. One may see a good man doing certain things regularly for years without being any wiser. What you want to know is *why* they are done. Then when you have found out the secrets, you want adequate opportunity to test your newly acquired knowledge. Practising on sitters—the only chance for most assistants—is most reprehensible. When you are helping me in the studio with the sitters I'll try to make it clear to you, as I go along, what I am aiming at. But what you do not understand you must always ask me about when the studio is free.

I see you have a rough print of that head we took of Mr. Black. We will consider it presently. Before doing so, however, I am going to play the schoolmaster, and go back to our former lesson. What did you learn? To select the better side, to consider what should be disclosed, and what should be hidden, to determine the lighting of the face, to understand the direction of the eyes. Yes, that's about all, and then my little paper has amplified those points.

On the whole I am pleased with this picture of Mr. Black. He looks pleased with himself. The very last thing to notice before exposing is the first thing a portrait is judged by—the expression. Look at the twinkle in the eye, the characteristic puckering of the mouth, when I was chaffing him. And yet a few seconds previously he was bored stiff. There is a Chinese proverb which says that a shopkeeper who would succeed must have a smiling face. Certainly, the operator-photographer should suggest cheerfulness. I can give no rule, no formula, that will enable you to make a stranger feel quite at home when there is a camera about, and yet if you cannot do that all the rest is in vain. "Expression" does not necessarily mean a grin. Nothing but a good knowledge of human nature, wide interests, and catholic sympathies, with an inexhaustible stock of good temper, will carry you to the highest class of portrait work. I believe in creating a good impression (or rather maintaining the good impression that was begun in the reception room), keeping up the impression all the time I am occupied with the client and finishing off on the same note. I have read a good deal of "uplift" American talk, advising the photographer to cultivate conversation suitable to the individual who is being taken. This is so much nonsense. Mr. Lloyd George needs no advice on political matters from me; I would not venture on a point of theology with a bishop, nor, while studying the contours of Mr. Chesterton, would I indulge in literary criticism. All the same, if that genial writer favoured me with a sitting, I might draw him about prohibition. I bring that in with an object. There are few persons who are not susceptible to flattery of some kind. A man who is before the public in any way likes you to know the fact; probably the less importance he is to society the more he dislikes being ignored. It comes to this, George, that the supreme study for the photographer is psychology. I had a

very morose church dignitary to photograph recently. I had seen in the local press that he had just returned from the South of France, where he had been in quest of health. I congratulated him on his improvement, and, knowing something of the Sunny South, I soon had him talking away cheerfully about his holiday. I got a few splendid negatives of him when he was completely off his guard, and the order has been most satisfactory. Talk of the right sort—it varies with every client—is a valuable asset.

Don't think, George, that I'm giving you too much philosophy, the so-called "practical" side of photography is comparatively easy. You may pose, light, expose and all the rest of it, and yet only give us the clothes, and the *outside* of the subject. The one essential point of a portrait that will give satisfaction is that it must be characteristic of the client. Just look up the "B.J." of March 17 last, and regard the portrait of Mr. Wastell, the President of the Royal Photographic Society. This picture is an admirable illustration for what I have been saying. Note the good outline, the tilt of the head, the fine drawing achieved by the lighting, and, above all, the "character" of the man. One need not be told that this subject possesses a sense of humour.

This portrait of Mr. Black is equally successful. Now I want to draw your attention to this point: two three-quarter face portraits may be taken of the exact same view of the face, both may be quite good, and yet in one case the eyes look to the front, in the other away from the camera. This is determined by the relative position of the shoulders. With Mr. Black we wanted to give him breadth, so you find he is looking away slightly in the way his head is turning. On the whole, there is not much interest in a man's shoulders, and, if a one-plate sitting, I would say get the eyes to the front. Few faces have just one tolerable point of view, and if two positions are being taken it is as well to make a considerable difference, even if more apparent than real, by altering the scheme. It is still the custom with careful workers to duplicate an important negative. A clever French photographer got me out of that habit, and I pass you on his advice. Never take two negatives *exactly* the same. Assuming the same position of face, have the body, and consequently the eyes, different. A slight modification in the size of head will also make a difference. The chances are that you reject one, but there is always another position to submit—probably after the first order has been put through. Of course, conceivably, one may have a subject that would allow of no alteration, save in exposure, but that's an extreme case. Get it into your head that it is sheer folly to expose four plates, which can only yield two poses, when, with very slight modifications, three or four may be proofed.

Now, do you see any faults in Mr. Black's picture? Do you notice anything that could be altered with advantage? There are a few minor points which we will take up later, but there is a serious fault in the lighting—a fault which I committed knowingly. You can't see it, George? Well, I'll give you a valuable five minutes, that will make you see things differently, and better.

You will have gathered that I think ears are usually unlovely, and that I prefer to hide one of them. That doesn't quite satisfy me though. The remaining one is always bold, and if not restrained, insists on forcing itself to the front, as it were. Now, hold out Mr. Black's portrait, think what I have been saying, and notice the face full of delicate detail, and the ear far too well illuminated. If you will just run down and ask Mr. Black if he can spare a few minutes, we will reconstruct the picture.

I'll leave you to it, George, to reproduce the pose and the lighting. I don't wish you ever to copy slavishly the work of another photographer, but it is splendid practice to take a picture, and build one up in the studio exactly like it, without wasting a plate. Only when you know exactly how to manipulate the blinds and camera for every different effect can you be said to have a grip of the technical side of good portraiture. Yes, I think that's about how we had him before.

Now, don't you see the ear? Well, we'll soon settle that. Fetch me down that little dark screen, the "black reflector," as I heard it called. Watch the effect as I waggle it backward and forward until I get a good shadow on the ear. Skilfully used, this screen is an enormous help. Not only does it tone down undue prominences, but it helps materially to "set back" the cheeks, improving the modelling, and rounding off sharp lines of dress or coat. Keep the screen as close to the side of the sitter as ever you can. Now, if you just expose a plate on this—never mind the expression—you will be able to file the two prints, making a good record of the lesson.

I left you to focus and space both of these heads yourself. I have to show you several little things about these seemingly simple operations, which make a great difference to the complete effect of the composition. But these points had better be taken in conjunction with the practice of vignetting (in front of the lens) and other camera manipulations.

V.—THE THREE-QUARTER LENGTH PORTRAIT.

Except for children, three-quarter length pictures should generally be the most numerous in the output of a studio. In the case of men, there is precious little of pictorial interest from the knee downwards, and in our fickle climate ladies, otherwise perfectly dressed, frequently wear shoes which are more for service than beauty. Good subjects for full-lengths are very rare, and as the three-quarter cuts out the ugly and the unnecessary parts, and gives more prominence to the head, it is deservedly popular.

Our clients generally tell us whether they prefer to be sitting or standing, but there is seldom any dictation, and the position or attitude is entirely at the discretion of the photographer. Now, George, I want you to get something new, something different into your work, and the first thing I would point out to you about "posing" is that there should be scarcely any. I am sorry to see that you have learnt all the stock tricks *which we all use at times*, and that there is too much of the hand on the pedestal for standing figures, and the book on the knees for sitting ones, to give your work distinction. Yes, yes, a man does lean on a pedestal, and a lady has been known to sit with a book on her lap; it is just because everyone leans on things or reads books, that these positions must be carefully watched. What we want to see a sitter doing is not what every other human being does, but what only one individual in the world does, or quite a simple action in that slightly different way peculiar to the sitter alone. The more your faculty of observation is cultivated, the quicker will you be to apprehend subtle differences and to show such knowledge in your work. Still, when you simply *have* to fall back on one of the old stock poses, make a feature of the lighting, and take great care over the expression.

Mind you, George, I don't want you to run away with the idea that I have a contempt for the methods of the old photographers. Behind the stereotyped posing of the early cabinet photographs, there was frequently a wealth of artistic knowledge. I can honestly say the same of the work of a few "cheap men" in the business, men who have, although making no great pretensions, all made comfortable incomes out of photographs that are a little different from "the usual thing." I look upon the making of portraits as the literary man regards the writing of a story. One who can only write about the fair hero, the dark villain, wedding bells, and the well-worn situations has no chance of success. Similarly, the photographer who serves up year after year the "conservatory" or the "library" (with the same stone accessory), never draws a blind, and seldom changes a case, is something of an optimist if he hopes to get a living out of such work. Now, I'll stop philosophy for a bit, and proceed to the prac-

tical. Bring Joe out of the dark-room, and we'll use him as a model.

Now, Joe, my lad, just stand down there. Look at him, George, both hands in his own pockets! That shows his inexperience and youth, doesn't it? Keep as you are, Joe. Now, what fault have you with this, George? Quite right, he is far too wooden, and the composition is the same at each side. Ah, no, no, don't move the sitter. Why do that, when you can get the same result by moving the camera? Get it firmly into your head, George, that the last thing you should do with a sitter is to "handle" him. If you have a fine, wide room like this to work in, shove the camera about from side to side to alter the point of view. Just here, note the broad principle of lighting involved in the relative positions of sitter and camera. Working diagonally across the studio, with the camera against the side light, the subject is more broadly lit, the scheme is "softer" than the normal. Reverse the procedure, of course without disturbing the blinds, and the composition will have more contrast and something of the "Rembrandt" appearance. I speak of working "across the light" and working "against the light" to indicate where the camera ought to be placed, taking an imaginary line down the centre of the studio as the normal "operating" platform. Well, given a scheme that is just a trifle too flat, working *against* the light will put more shadow and contrast into the picture, while harsh lighting may be softened by working *across* the light, and *every change in the camera's position to right or left means a modification of the lighting.* Always bear that in mind when shifting the camera, instead of disturbing the sitter.

Yes, that's better, now that we get the body a little to the side, and each arm discloses a different set of contours. I see the blinds weren't closed after the last sitter. Substantially the lighting is just about right. Young faces are best, as a rule, without any "effects" in lighting. I think, however, no doubt inspired by the thought of quick exposures, that most of us use too much light on our pictures of children. True, the rounded little faces should not be in a low key, but care should be taken in conserving roundness that we don't get the snub nose and the puffy cheeks reduced to the one plane. Now look at Joe. He's got plump, youthful cheeks, but if I were to let in more front light it would broaden his face, and give the impression that he had a gumboil. You've got that focussed? See that you vignette him off above the knees, George, for the outline of unpressed trousers is best subordinated. A lad of this age and disposition may be encouraged to smile, an expression tolerable in a care-free youth might look quite undignified in a man of mature years. There now, I've exposed that, George; we'll go over it critically in the negative. Don't move away, Joe, I will need you for a few minutes yet. Which leg does a man stand on, George? Seems a funny question, doesn't it; but few persons know how to stand properly, and fewer know by regarding a picture whether the subject is standing on the right or the left leg, or if the weight is distributed equally between the two; and yet, although it is a very simple matter, the student must be in no doubt, otherwise he will continually be at sea in his full-length and three-quarter pictures.

Well, then, a man only stands on one leg at a time, unless a soldier on parade. The leg on which the weight of the body is thrown should be rigid, the other more or less bent. Actors and others who have to consciously study their appearance know how gracefully the body may be carried by thinking of the feet, and photographers should certainly know the rules of deportment.

At the beginning of this morning's talk, George, I counselled you to "pose" as little as possible, and I always try to make the sitter give me the key to the position. As Joe wasn't a bit nervous, he just stood right at once, hands in pockets, the body inclined slightly forward, the head almost straight above the rigid leg. See, he has shifted on to the other foot now, and if we were to take another plate the picture would have a leaning-back tendency—that is, of course, if we didn't alter the head as well. Well, a human being stands on one leg at a time, but does it matter which? Is it arbitrary, or has it any significance?

A clever artist with whom I once lived used to say that he had a definite rule in the matter. "Make a woman stand on her fore leg, and a man on his hind one, and you can't go far wrong," was his advice. Joe was standing on his "fore" leg, but he's not a man yet. There is a great deal in the rule of my artist friend. With the rigid leg in front and the body inclined forward, movement and youth are better suggested than when the subject seems to have sunk back tired on the opposite limb. Now, although the standing problem is of paramount importance with full-length pictures (I shall come back to it again), even in three-quarter lengths the placing of the feet determines the ease or otherwise of the portrait.

A hands-in-pockets picture like this presents few difficulties, but let us just think over a few points common to this and similar three-quarter lengths. An ordinary dark suit possesses little aesthetic beauty, so the aim should be to keep the clothes and background in low key. I need scarcely tell you that a light background shows a dark figure to advantage, and *vice versa*, but one must always be on the alert in practice, and settle each problem on its merits. A world of difference may be made by changing from a very dark to a very light ground, but one must think of the portrait and background as a complete composition. Selection and choice in this respect must be guided by the old test question of disclosing or subordinating. We can go into the "losing and finding" of outlines better with full lengths, so we will defer that to further consideration.

Take your hands out of your pockets, Joe, and sit down somewhere. Look at him, George, in that big chair like a tired old man. That would never do. It only needs a book, and a cathedral light to make a clergyman of him. Stand up again, my lad, straddle one leg over this sofa as if you didn't care a hang about anyone. That's the goods; now take out your cigarette case. No, that packet of fags won't do; I'll lend you my case. Look at that now, George. See how easily he is "posed," how simply the hands are employed, and yet how natural the whole thing is. If Joe ever reads a book, none of his friends see him at it, and certainly I often see him sitting up on tables and benches, when I might be better-pleased if he was doing an odd bit of work, and it doesn't need a Sherlock Holmes to tell that he is addicted to fags. Well, George, in this case, we occupy the hands without any difficulty, and get something like a portrait of a youth. Thank you, Joe, you have done very well. I hope you have been paying some attention to what I have been saying, for I hope soon to take you into the studio with me.

Now, George, you can have those few boxes of plates which I stopped using on account of their slowness. Provided you are always trying hard, and promise to give up the book and pedestal, the front face, and the two-legged portrait, you may experiment away until I further restrict your artistic endeavours

J. Effel.

Photography and Crime.—The important part played by photography in all great criminal cases nowadays is, of course, well known and appreciated, but most people will be surprised to learn (says last Sunday's "People") that the cost of the Bournemouth murder trial in this connection from first to last amounted to between £1,800 and £2,000. This sum included, in the first place, the cost of photographs of the scene of the murder and of the unfortunate victim, and the circulation broadcast of facsimiles of the decoy telegram sent by the murderer, together with specimens of his handwriting.

JUDGMENT AND THE EXPOSURE METER.

[Even when the instructions for the use of an exposure meter are strictly followed, considerable opportunity still remains for the exercise of judgment in determining the exposure to be given under various working conditions. The respects in which due allowance requires to be made are very usefully dealt with in the following article from the "Camera," particularly as regards making allowance for the scale of tones in the subject.]

The difficulty of estimating the correct exposure to give, under varying conditions, is sufficient to account for the number of aids offered in the forms of exposure-meters and tables, but to obtain the maximum help from such guides the user should be acquainted with the factors which affect exposure, which are:—

1. Actinic strength of the light illuminating the subject.
2. Contrast range between lightest and darkest parts of the subject.
3. General tonality or "key"—*i.e.*, whether most of the material is light or dark.
4. Pronounced colour, especially in the immediate foreground.
5. Distance of important parts from the lens, if much nearer or further away than usual.
6. Size of lens-stop employed during exposure.
7. Speed of the plate or film, and its sensitiveness to different colours.

The strength of the light is pretty accurately measured in meters like the Watkins and Wynne type, by noting the time taken for a section of the special sensitized paper supplied to darken to the same shade as the "Standard tint" attached to the dial, this being known as the actinometer time, but in the case of ordinary exposure-tables, or calculators designed on the same principles, where the power of the light is listed under such heads as "intense sunlight," "diffused," "dull," etc., the user must depend upon his own judgment as to just what conditions fit these terms, and opinions are liable to vary considerably if some systematic definition is not applied, the best visual guide being the intensity of cast-shadows in direct sunlight, together with the colour of the atmosphere.

Intense sunlight may be said to exist when the air is very clear and objects in the foreground cast sharp, deep shadows, which present great contrast with the lighted portions of the subject. The term "good" or "bright" sunlight fits when a very slight colourless haze subdues the sun's rays a little, making the shadows somewhat less intense, but still well-defined at their edges. Such headings as "diffused sunlight" and "hazy sun" are applicable when cast-shadows are faint and blurred in outline. "Cloudy-bright" expresses the condition when the sun is shut off from view by broken masses of cloud, preventing direct shadows being cast, yet affording a fair amount of indirect illumination reaching the subject. "Dull" or "cloudy" indicates an entirely overcast sky of a grey blue, while "very dull" should be applied when the sky is of a dark leaden shade, also in the case of twilight scenes, during a snowstorm and when rain is falling steadily. When the atmosphere is more than usually tinged with yellow or orange, for the time of day, the indicated exposures on printed tables can safely be doubled at least, even though orthochromatic plates or films are employed, and even more allowance is essential to prevent under-timing, if ordinary emulsions are being used, owing to their slight sensitiveness to such tints.

Our second, third and fourth factors—contrast, proportion of light and dark tone in component parts and colour vary with the character of the subject and lighting. The intensity and concentration of the latter determines the degree of contrast between the lighted and shadow portions of each object, but the local tone or colour of each part also causes a range of tones besides those due to accidents of light and shadow, and it is a combination of the two, as a rule, which produces the effect observed. A view, containing material of almost uniform local tone-value, appears flat in a dull light, because of the absence of those accents due to the play of light and cast-shadow, whereas one made up of objects of contrasting local tone, say a white house amid a setting of dark foliage, will present a considerable amount of gradation under the same conditions. For these reasons material having a longer scale of local tone than usual will be likely to exhibit extreme contrasts in intense light, particularly when portions of the lightest coloured objects receive the full effect of the sunlight, while parts of the darkest objects remain in shadow. Here is where the direction from which the light comes may entirely alter the tonal scale.

When the scale of contrast is moderate, and the greater part of the subject-matter in an outdoor view is light in tone, it may be classed under such heads as "open landscape" or "landscape with light foreground," even though the principal object is within 10 ft. or so of the lens, but when extremely deep shadows or dark objects fill a noticeable amount of the picture-space, or much of the material is composed of the less actinic colours, such as brilliant yellows and reds in autumn foliage, the same exposure may well be given an open scene as that allowed a "landscape with heavy foreground."

Since beginners are sometimes in doubt how to classify material under certain of the headings commonly used in exposure-tables, the following suggestions are given:—

Average Landscape.—A moderately open section of scenery without any dark masses of foliage nearer than about 50 or 75 ft. from the lens, but with enough material of this sort, or something similar in tonal quality, to fill from a third to one-half the total area of the picture. A street-scene, with light, open foreground and low buildings, also views of a building at a sufficient distance to show the whole of the structure, would come into the same class in the matter of exposure.

Open Landscape.—One with a clear foreground, such as a grassy meadow, and only a limited amount of dark tone in the middle distance, say a 100 yards away, which can practically be disregarded in timing the exposure. Most river and lake scenes in which water occupies most of the foreground area, can be classed the same, also shore views, with dark rocks in the foreground.

Snow, beach-scenes and *shipping* are usually listed as needing but one-fourth the exposure of an average landscape, but this applies only when such subjects have a clear, open foreground, or one containing very light-toned objects, it being assumed any dark material which may be included is at a sufficient distance to cover but a small space in the picture. An exposure, which would be sufficient for snow-covered hills or a distant vessel, will not register detail in the shadow portions of nearby tree-trunks or a ship's hull painted in dark colours, even though the surface of snow and water does reflect light into the shadows, thus reducing their depth; consequently, in dealing with subjects of this type, one should be guided by the area and general depth of the shadow tones rather than the brightness of the high-lights.

Regarding the fifth factor, that of distance between lens and subject, when greatly in excess of the range presented in the different subjects already mentioned. Other things being equal, very distant objects, such as a mountain peak, taken with long-focus or telephoto lenses, which cut out the immediate foreground, because of the narrow view-angle covered, require less than normal exposure owing to the refracted light and semi-opacity of the intervening atmosphere lessening the intensity of dark parts and reducing the general contrast. Very near objects call for extra exposure, not only because of the practical absence of the conditions just mentioned, but the fact that the lens must be racked out considerably beyond

its normal equivalent focus to secure a properly defined image, which, for the time being, reduces the effective speed of any given stop used. Thus, if the distance between lens and plate is once-and-a-half the normal focal length, a stop marked $f/8$ is really working at an effective aperture of only $f/11$, which, as every practical worker knows, calls for twice as long an exposure. Such conditions are always encountered when photographing small objects to a fair-sized scale.

Our sixth factor, the size of lens-stop, is taken into account in all exposure-guides, but subject to an allowance for the change in effective value under the conditions just set forth.

The last factor, speed of plate or film, is a measurable one, within the small percentage of variation in speed of different batches, and every standard brand is assigned a certain speed-number by the makers of meters and tables. Some workers, however, prefer fuller or shorter timing than others, so when the desired results are not obtained by following the listed speed of the plate used, one has merely to choose a lower or higher number to suit personal requirements.

In using meters of the actinometer type, it is important to measure the power of the light correctly, and as the method of doing so varies somewhat with different instruments, the maker's instructions upon this point should be carefully read and kept in mind.

Some people seem to experience difficulty in determining the exact instant when the sensitive-paper reaches the shade of the standard tint on the dial or face of a meter. This is readily overcome by holding the meter at about arms' length and observing the depth of the tint, instead of looking for a perfect match in colour, since there is often a slight discrepancy in the latter, which should be disregarded. In timing the darkening of the test paper it is advisable to hold one's watch alongside the meter, where both can be seen without shifting the eyes, cover the unexposed section of paper with one thumb until the second-hand of the watch reaches the starting point on the dial, then begin the exposure of the paper, and as soon as it reaches the correct depth note the number of seconds taken. Somewhat less care is needful in weak light, since the paper then takes much longer to darken and there is less chance of error creeping in.

A matter which has nothing to do with the correctness of the timing, indicated by a meter, yet may make it inaccurate from a practical view-point when giving shutter exposures of rather short duration, is the light passing efficiency of the shutter, also whether the marked speeds are approximately true, which is not always the case. In fact, the higher speeds of between-lens shutters seldom come up to their rating, but such differences as may exist in shutters, kept in good working order, is offset by the fact that even the best of shutters, working at the diaphragm opening, cannot be 100 per cent. efficient in light passing power for the duration of the exposure, as an appreciable portion of the time is taken up by the opening and closing of the shutter-blades, the practical effect of which upon the volume of light is equivalent to using a smaller lens-stop. As the blades of the best shutters move very rapidly at whatever speed the shutter is set, it is evident that their efficiency is highest on the slower speeds, since the blades then have an opportunity of remaining wide open for a longer time than is the case at a higher speed, where there is only sufficient interval of arrested motion between opening and closing to permit the mechanism to act. The result is that a shutter, which may be 80 or 90 per cent. efficient in light passing power on such slow speeds as 1/5 or 1/10 second, will probably not be better than 60 per cent. at 1/100 or 1/150. As before stated, this loss is very well balanced when the actual higher speeds are not up to their markings, but when using a shutter, whose speeds are known to be accurate, it is a good plan, whenever possible, to figure upon giving more time, or using a larger lens-stop than the meter-reading calls for on brief exposures to guard against loss of shadow detail from under-timing.

WILLIAM S. DAVIS.

THEORY AND PRACTICE OF DEPTH OF FOCUS.

II.

[In the preceding of the present series of chapters the phenomena of vision, which enter into the question of depth of focus, were generally considered. Depth of definition—that is to say, the distance through which the focussing screen can be moved forwards and backwards from a position of critical focus when photographing a flat object—was the subject of short treatment, from which it was shown that this "depth" is always proportional to the working relative aperture of the lens irrespective of its focal length. The present chapter is devoted to the so-called hyperfocal distance, a term which unfortunately has been used in several different senses by writers on depth. In Chapter III. we shall come to the formulæ relating to the furthest and nearest distances (from the lens) to which depth extends when focussing on a given distance with a lens of given focal length and diameter of aperture.]

THE factors which enter into depth of focus are most simply displayed in reference to a condition of everyday importance in hand-camera photography, viz., the degree to which an object (focussed when at a very great distance) may approach the camera without itself becoming perceptibly unsharp in the photograph, and, of course, without sacrifice of sharpness in more distant parts of the subject by altering the focussing.

The term *hyperfocal distance* is used by writers on this subject, but unfortunately in three different senses. It is therefore necessary to show these differences and to explain the meaning which we will attach to this term.

If an object at a great distance (the so-called infinity) be sharply focussed, it is found that, without altering the position of the lens, a comparatively near object is still "in focus," that is, it is rendered without perceptible unsharpness. By the description "in focus," or "without perceptible unsharpness," is meant the reproduction of a point in the nearer object as a disc of admissible diameter. It is the distance of this nearer object from the lens which, by most English writers, is called the *hyperfocal distance*. We will, therefore, adopt this use of the term, and denote it by the symbol H.

Next, let the sharpest focus be obtained on an object at such a distance that objects up to the extreme distance are rendered without perceptible unsharpness. It will be found that the difference between hyperfocal distance and the distance of sharp focus when obtaining infinity without perceptible unsharpness is very small.

Lastly, suppose we find how much nearer to the lens an object may be brought (after focussing on an object at the distance for "focus" at infinity) without becoming perceptibly unsharp. As will be shown, it may be brought almost exactly half the hyperfocal distance towards the lens.

By French writers, and also by some English, the term "hyperfocal distance" is applied to this half-distance. We will call it *distance of nearest "focus" when obtaining equal "focus" at infinity.*

We can now proceed to derive the formulæ for these three distances.

Hyperfocal Distance.

In fig. 4*, $A\,B$ and $C\,D$ together represent the largest pencil of rays from an infinitely distant object point, which passes through the diaphragm $B\,D$ and comes to a focus at Z. $B\,P$ and $D\,P$ represent the image-forming rays bounding the largest pencil from a nearer object having its focus beyond Z, namely, at P. $K\,K$ represents the focussing screen. If, then, the convergent pencil, which has its focus at P,

* For the sake of clearness in this and the succeeding diagrams the aperture of the stop and the disc of confusion are shown on a greatly exaggerated scale.

has a cross-section (of diameter, $G\,G = c$) on the ground glass equal to the maximum disc of confusion, the axial distance of the nearer object from the diaphragm is the hyperfocal distance as above defined.

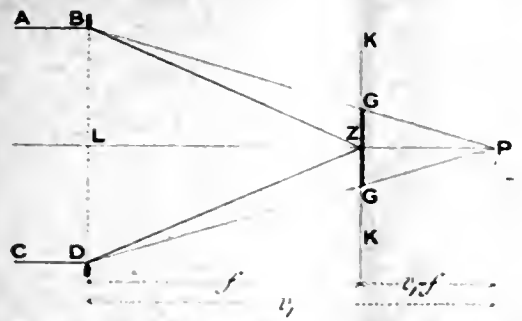

Fig. 4.—Illustrating formation of image of an object at the hyperfocal distance. A pencil of rays $A\,B\,C\,D$ from an infinitely distant object comes to a focus on the focussing screen $K\,K$ at Z. If the cross-section $G\,G$ (in the plane of the focussing screen of a pencil from a nearer object (having its focus at P) is equal to the admissible disc of confusion, the object is at the *hyperfocal distance* $= \frac{fd}{c}$, where f is the focal length of the lens and d the diameter of the stop $B\,D$.

We will use the following symbols for the quantities concerned:—

f, focal length of lens.

d, diameter (effective) of diaphragm.

c, diameter of admissible circle of confusion.

u_1, u_2, u_3, object distances.

v_1, v_2, v_3, image distances.

Thus, in fig. 4, u_1 is the distance of the nearer object from the diaphragm and v_1, the distance of its image.

From the geometrical construction (the similar triangles $B\,D\,P$ and $G\,G\,P$)—

$$\frac{c}{d} = \frac{v_1 - f}{v_1}$$

Since v_1 and u_1 are conjugate focal distances,

$$\frac{1}{v_1} + \frac{1}{u_1} = \frac{1}{f}, \text{ i.e., } v_1 = \frac{u_1 f}{u_1 - f} \text{ and therefore } \frac{c}{d} = \frac{f}{u_1}$$

and u_1, or H, $= \frac{fd}{c}$ . . . . . (4)

In words, *the hyperfocal distance is equal to the focal length multiplied by the diameter of the stop, and divided by the diameter of the admitted disc of confusion.*

Now of these three quantities in the formula, the focal length and stop diameter are determined by the particular lens in use and, within limits, each can be singly and separately varied. On the other hand, the diameter of the disc of confusion is a quantity which, according to the older views on depth is arbitrarily chosen, say, 1/100 or 1/250 of an inch for fair and critical definition. According to the more modern view, it should be a certain small fraction of the camera extension (which, in this case, is the focal length) corresponding with the angle of sharpness of vision.

If we retain the same standard of definition for large and small pictures, then, plainly, the distance of nearest "focus," when focussing on infinity, is separately proportional to the diameter of the stop and to the focal length of the lens. If either of these is halved, the hyperfocal distance is also halved. But, on the other hand, it is in accordance with the conditions of vision that, when using a longer focus lens and getting a larger picture, we can therefore allow a proportionately larger disc of confusion, because the print should be viewed from a greater distance. If, then, in this order of ideas, a larger disc of confusion is allowed proportionally with an increase in the focal length, that is, if c is always to be in the same proportion to f, this distance of nearest focus is singly and solely proportional to the actual diameter of the stop. This was the crux of the controversies which raged years ago, when this latter view of depth was put forward by Mr. W. E. Debenham, some years before it was advocated in a more scientifically developed form by German opticians. In a later part of these articles we shall endeavour to show that formulæ devised from either the modern or older view require modification according to the particular circumstances prevailing in the taking of the negative and viewing of the print.

Formula (4) may be put in other forms. Instead of including the actual effective diameter of the stop, the ratio $\frac{\text{focal length}}{F.\ N^\circ}$ can be used, so that the formula becomes

$$\text{Hyperfocal distance} = \frac{f^2}{F.\ N^\circ \times c} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4a)$$

In words, *the hyperfocal distance is equal to the focal length multiplied by itself, divided by the F. N° and also by the admitted diameter of disc of confusion.* If a standard of 1-100th of an in. be adopted this becomes

$$H = \frac{100 f^2}{F.\ N^\circ} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4b)$$

Thus, adopting a disc of confusion of 1-100th in., the hyperfocal distance when using a 6-in. lens of *f*/8 aperture is

$$\frac{100 \times 6 \times 6}{8} \text{ in.} = 450 \text{ in.} = 37 \text{ ft.}$$

On the other hand, if it is held that the disc of confusion should be, say, 1-2,000th of the focal length, formula (4) obviously becomes

$$H = 2{,}000\ d \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4c)$$

that is, the hyperfocal distance is 2,000 times the actual effective diameter of the stop. In a later chapter it will be shown how very simply this last formula follows from considerations based on conditions of vision.

Distance of sharp focus when obtaining infinity in "focus."

This is the nearest distance of an object which can be focussed with critical sharpness at the same time that objects in the extreme distance are rendered by definition consisting of discs of confusion of the maximum admitted diameter.

Adopting the same lettering as in fig. 4 a pencil of rays from an object O at some finite distance u_2 is brought to a point focus P_1 on the focussing screen $K\,K$ (fig. 5). If, now, the pencil of rays $A\,B$, $C\,D$, from an object

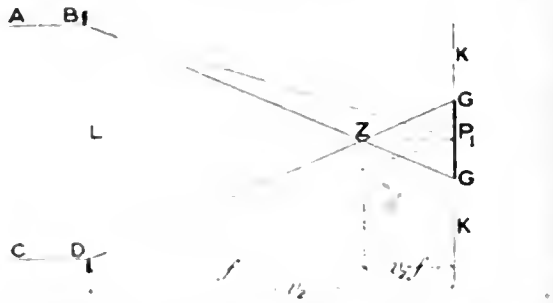

Fig. 5.—Illustrating formation of image of object at distance of sharp focus when obtaining infinity in "focus." P_1 is the sharp image on the focussing screen $K\,K$, of an object at such a distance that a point in an object at infinity is rendered on the focussing screen as a disc $G\,G$ of the admitted diameter c. The distance of the object is $\frac{fd}{c} + f$.

at infinity, forms a disc of confusion $G\,G$ of the maximum admitted diameter in the same plane as the sharp image of O, the distance of O from the stop is the distance, as just defined.

From the construction (the similar triangles $B\,D\,Z$ and $G\,G\,Z$

$$\frac{c}{d} = \frac{v_2 - f}{f}$$

As before $v_2 = \frac{u_2 f}{u_2 - f}$

whence u_2 (distance of the object) $= \frac{fd}{c} + f$ . . . . (5)

that is, the distance is greater than the hyperfocal distance by one focal length of the lens.

It is the theoretical distance on which to focus in order that all objects up to the extreme distance may be without perceptible unsharpness, according to the standard adopted for the disc of confusion, but it differs so slightly from the hyperfocal distance that the latter serves equally well.

Formula (5) may be written:—

$$\frac{f^2}{F.\ N^\circ \times c} + f \quad . \quad . \quad (5a)$$

If, however, we adopt as the standard of the admissible disc of confusion, 1-2,000th of the distance from which the print is, or should be, viewed, that is 1-2,000th of v_1 in fig. 4, there is no difference between this

distance and the hyperfocal distance: each is equal to 2,000 times the actual effective diameter of the stop.

$$u_2 = 2{,}000d \quad . \quad . \quad . \quad . \quad . \quad . \quad (5b)$$

Distance of nearest "focus" when obtaining equal "focus" at infinity.

The distance of an object in critical focus, which permits objects up to infinity to be rendered without perceptible unsharpness, has an important property. From fig. 5 we have found the value it has in order that depth may extend to the extreme distance. Let us now see how far depth extends towards the camera. In fig. 6, as in fig. 5, let

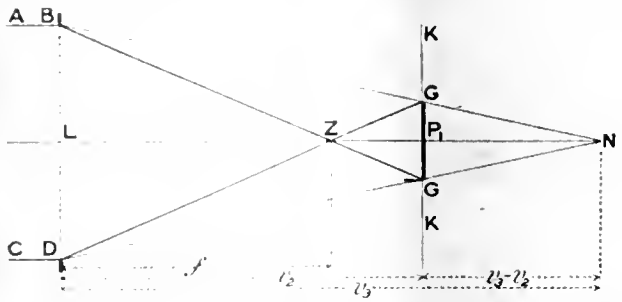

Fig. 6—Illustrating formation of image of object at distance of nearest "focus" when obtaining equal "focus" at infinity.

N is the image of a nearer object at such a distance that the cross-section in the focussing screen of its pencil of rays is also equal to the admitted disc of confusion *G G*. The distance of the object is therefore exactly half $\frac{fd}{c} + f$.

an object point at infinity form a disc of confusion on the ground glass of the maximum admissible diameter *G G*. An object at the distance of $\frac{fd}{c} + f$ is then in critical focus. (For the sake of clearness rays from this object are not shown). Let *O* be an object at such a lesser distance u_3 that rays from it also form on the screen discs of confusion of the maximum admitted diameter. The image of *O* is therefore at *N*, and the distance from *N* to the diaphragm is the conjugate image distance of the required object distance.

From the construction (the similar triangles *B D Z* and *G G Z*)—

$$\frac{d}{c} = \frac{f}{Z P_1}$$

$$\text{i.e. } Z P_1 = \frac{fc}{d}$$

Similarly from the triangles *B D N* and *G G N*

$$P_1 N = \frac{c v_3}{d}$$

But $Z P_1 + P_1 N = v_3 - f$

whence $v_3 - f = \frac{fc + v_3 c}{d}$ and $v_3 = \frac{f(d+c)}{d-c}$

But $v_3 = \frac{f u_3}{u_3 - f}$

Therefore $u_3 = \frac{fd}{2c} + \frac{f}{2}$ . . . . . (6)

This is seen to be exactly one half the distance of sharp focus. In other words, when focussing on this distance, depth extends backwards to the extreme distance and forwards through half the distance focussed on. It is plain from the diagram that this is the greatest extent of depth obtainable and hence in theory the distance according to formula (2) is the best focussing setting for a fixed focus camera. The difference between it and the hyperfocal distance, is, however, so small (one focal length) that the latter serves just as well. Objects up to one-half the hyperfocal distance are then obtained without perceptible unsharpness according to the standard of disc of confusion adopted.

If, as already set forth, a variable standard for the admissible disc of confusion in the print be adopted, e.g. 1-2,000th of the viewing distance, the distance of nearest focus when obtaining equal focus at infinity is 1,000 times the absolute diameter of the effective stop.

The results obtained from the foregoing constructions will perhaps be more easily followed if we put them down in a table.

TABLE II.

1.	Formula. 2.	For disc of confusion of 1-100th of an inch formula is: 3.	For disc of confusion of of 1-2,000th of viewing distance formula is: 4.
1. Hyperfocal distance, viz. distance of nearest "focus" when focussing on infinity	$\frac{fd}{c} = \frac{f^2}{F.N^\circ \times c}$	$\frac{100f^2}{F.N^\circ}$	$2{,}000d$
2. Distance of sharply focussed object such that objects at infinity are in "focus" (practically equal to the hyperfocal distance) . .	$\frac{fd}{c} + f = \frac{f^2}{F.N^\circ \times c} + f$	$\frac{100f^2}{F.N^\circ} + f$	$2{,}000d$
3. Distance of nearest "focus" when obtaining equal "focus" at infinity (practically half the hyperfocal distance)	$\frac{fd}{2c} + \frac{f}{2} = \frac{f^2}{F.N^\circ \times 2c} + \frac{f}{2}$	$\frac{50f^2}{F.N^\circ} + \frac{f}{2}$	$1{,}000d$

For practical purposes, the odd f and $f/2$ in the horizontal lines 2 and 3 are negligible. The formulæ in these lines then become equal, respectively, to the hyperfocal distance and half the hyperfocal distance.

The Two Properties of Hyperfocal Distance.

To repeat, the above table is a reminder of the two properties which, for practical purposes, are possessed by the hyperfocal distance:—

(1) It is the nearest distance of objects rendered with the maximum admissible disc of confusion when focussing on the extreme distance.

(2) It is also the distance on which to focus sharply in order that objects in the extreme distance shall be rendered no more unsharp than the admitted disc of confusion. When so focussing, objects distant half the hyperfocal distance from the camera are also rendered with the maximum admissible disc of confusion.

It is hoped that figs. 4, 5 and 6 exhibit these properties as well as can be done by diagrams based on the image-forming rays conjugate to the actual distances concerned.

The Stop for a Required Hyperfocal Distance.

It may sometimes be required to ascertain the stop to be used in a lens in order to yield a given hyperfocal distance. If, according to formula (4*a*) based on a disc of confusion of 1-100th in., the hyperfocal distance is equal to 100 times the square of the focal length divided by the *F.* No., if follows that the *F.* No. required to give any hyperfocal distance *H* is equal to 100 times the square of the focal length of the lens divided by the required hyperfocal distance, that is:

$$\text{Required } F.\text{ No.} = \frac{100f \times f}{\text{Required } H} \quad . \quad . \quad . \quad . \quad . \quad (4d)^*$$

For example, the stop to be used to give a hyperfocal distance of 50 ft (= 50 in. × 12 in.) with an 8-in. lens and maximum unsharpness of 1-100th in. is:

$$\frac{100 \times 8 \times 8}{50 \times 12} = \frac{6{,}400}{600} = f/10.7$$

At this aperture objects up to 50 ft. from the camera will be in "focus" when focussing on infinity; and objects from infinity to 25 ft. when focussing on 50 ft.

The example serves to illustrate an elementary rule of depth of focus, viz:—

By stopping down the lens (after having focussed on an object) in order to bring infinity into "focus," depth of focus is thereby also extended half the distance of the object towards the camera.

This is only another way of saying that by stopping down the lens to the required degree the distance of the object becomes the hyperfocal

* According to the view that the disc of confusion should be a small fraction, e.g. 1-2,000th of the image (i.e. viewing) distance, the actual diameter of stop required for a given hyperfocal distance of *H* is *H* divided by 2,000 (see Formula 4c).

distance and exhibits the property No. 2 mentioned above. It is a particular case of a general rule in depth of focus of importance in photographing near objects. Consideration of the rules governing this distribution of depth on the far and near sides of the object in sharp focus must be reserved for another article. G. E. B.

(To be continued.)

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION. CONGRESS PROGRAMME.

We give below a few extracts from a communication which has reached us from the P.P.A.:—

Mr. Reginald Haines reports good progress with the Congress programme. The items have a very wide range of interest, and from the rough drafts we are able to give a few advance details. The committee has endeavoured to make as much change from the old style of Congress as possible, inasmuch as the Gallery is the finest and most suitable obtainable in London. From a social point of view it offers every comfort.

The trade exhibits are shaping well, and by what we hear from Mr. Wakefield the room will be unique in its appearance, and offers great facilities of getting right away with the business. There seems to be great enthusiasm amongst the trade exhibitors to give the members something of real interest.

In arranging the programme every consideration has been given to the trade exhibits. Every firm who is exhibiting will be one with us, and we sincerely hope members will appreciate these firms to the extent of always dealing with them. They have come forward and co-operated with us in this unique birthday celebration. Without giving full and definite dates and times these items will be of interest.

Monday Morning (Sept 11).—On the first day all members will be expected to go to the Gallery and sign the register, receive their badge number (registration fee 1s.), and here they can receive any information desired and obtain a complete programme and catalogue for 6d. Beyond these two small official charges all other expenses will be personal. The official opening will take place some time during the day, it depends entirely upon the personage who officiates at the ceremony. The President will deliver his address of welcome after the official reception in the Gallery by the President and Council.

Tuesday (Sept. 12).—The morning will be devoted to visits to several places of interest not yet fixed. After this a friendly lunch will be arranged at the Gallery at 1.30. In the afternoon there will be a very important lecture, and the evening will be devoted to Mr. Juan C. Abel, the general secretary of the A.P.A.

Wednesday (Sept. 13).—It is suggested to visit the National Portrait Gallery, and have the portraits described by one who knows. In the afternoon the trade stallholders intend interesting every member with their new apparatus and methods. In the evening Mr. MacDonald, the great "photographer of men," who again seeks his subjects in New York, but is proud to be a Scotchman, will give us a real treat. He is a man brimful of ideas useful to us all.

Thursday (Sept. 14).—A very interesting trip is being arranged to Windsor Castle by river and motor for this day. The costs will be very moderate. Special facilities are being granted. The evening will be perhaps the most unique feature of the Congress—the entertaining of assistants. It is hoped that at least 300 will be in attendance at this our birthday party to the young life of photography. Music and refreshments will be provided, and a real jolly evening is expected.

Friday (Sept. 15).—The details for this day are not quite fixed, but, among other events, we expect to pay an official visit to the London Salon of Photography. We feel sure this will interest many photographers who have never realised the power of pictorial photography. The annual general meeting must, of course, not be forgotten. It will be the most important official meeting of the Congress, and should be attended by every member. At the meeting the new President will be elected, and the evening devoted to the annual dinner at Prince's Gallery.

Saturday (Sept. 16).—The Royal Photographic Society have invited us to visit their exhibition on this day. This is indeed a welcome sign of the brotherhood of all photography and its vast number of workers.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Princes Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

Patent News.

Process patents applications and specifications—are treated in "Photo-Mechanical Notes."

Applications July 31 to August 5:—

Sensitive Materials.—No. 21,363. Photographic plates, films, etc. T. Thorne Baker.

Instantaneous Photography.—No. 21,253. Obtaining photographs from moving objects. H. L. Cooke.

Aerial Photography.—No. 21,031. Aerial photography. M. N. MacLeod.

Reflex Cameras.—No. 21,474. Reflex cameras. R. G. Matthews.

Cameras.—No. 21,053. Cameras. A. E. Norton.

Developing Apparatus.—No. 21,038. Frame for development of photographic films, plates, etc. Pathé Cinéma Anciens Etablissements Pathé Frères.

Camera Adaptor.—No. 21,244. Adaptor for photographic cameras. E. Snell.

Stereoscope.—No. 21,437. Stereoscope. A. E. Stanley.

Cinematography.—No. 21,223. Cinematograph, etc., projection apparatus. E. N. and J. E. Thornton and R. W. Wood.

Projection Apparatus.—No. 21,227. Apparatus for optically projecting from films. E. N. and J. E. Thornton and R. W. Wood.

Cinematography.—No. 20,851. Cinematographic, etc., screens. H. Dewey.

Cinematography.—No. 21,224. Spool cases for cinematograph, etc., projection apparatus. E. N. and J. E. Thornton and R. W. Wood.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

A Reflector for Studio Lighting.—No. 182,508. (June 14, 1922.)—This invention consists of a whitened, or light tinted, tunnel-shaped reflector, curved, rounded, or polygonal in transverse section as to its side and roof and of sufficient dimensions to permit of the posing or arrangement within itself of the persons or objects to be photographed. The reflector may consist of a framework covered with sheets of canvas, thin wood, metal, or other suitable material, or it may be of any other construction em-

bodying the features claimed as novel in the application. The end of the tunnel behind the sitter is more or less occupied by curtains or a background, the opposite extremity having arranged across it an end-screen or reflecting surface, light in colour and calculated to throw back upon the sitter any needed light that might otherwise escape from the tunnel unused. Such end-screen may actually close in the tunnel end, as shown in fig. 2, in which case it should be furnished with an opening for convenience

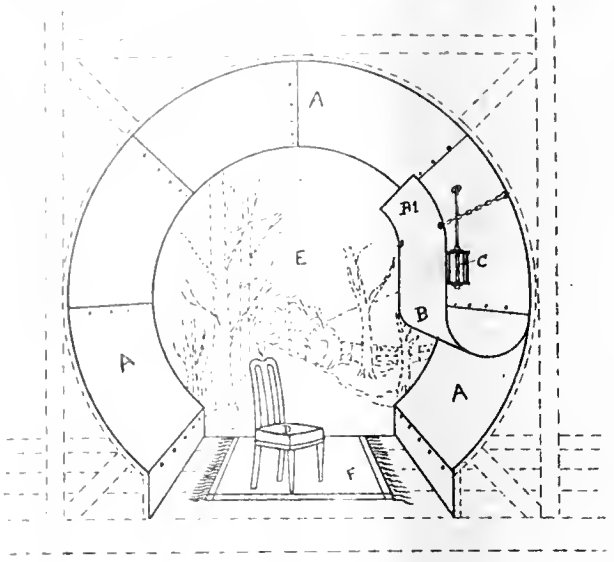

Fig. 1.

of access, or the screen may be arranged at a sufficient distance from the tunnel to admit of persons readily entering the latter. The front-lighting effects produced by the end-screen can be modified by the familiar expedient of having dark curtains slideably arranged in front of the latter in order to reduce or eliminate at will its capacity for reflection.

The source of light, which may consist of one or more arc lamps or of any other approved illuminating appliances, is placed within the tunnel or arranged outside the latter so as to light up the interior of the same through suitable openings or through portions of the tunnel formed for this purpose of a translucent substance. It has been found in practice that the best results are obtained when the illuminant is placed within the tunnel at one side of the same, the sitter being shielded from the lamps' direct rays by a light-coloured screen, opaque or slightly translucent in character according to the effect desired, and curved as to its

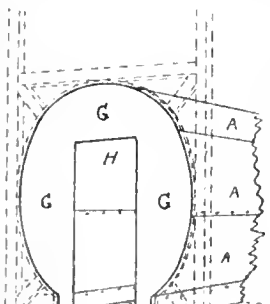

Fig. 2.

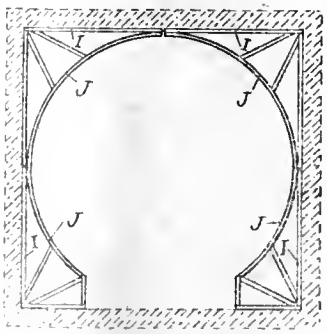

Fig. 3.

free upper portion in a direction roughly parallel with the roof of the tunnel, as shown in fig. 1. Where this arrangement is adopted small parts of the tunnel wall in proximity to the lamps may be made removable to afford access to the lamps for cleaning purposes.

An easily portable form of the tunnel-shaped reflector consists of a set of four rectangular frames, having curved inner surfaces suitably covered with light-coloured fabric, the whole being of such dimensions and transverse section that, upon the frames being fixed, respectively into the angles made by the side walls of a room with its ceiling and floor, as shown in fig. 3, and being used in conjunction with such front lighting reflector-screen as has been already described, the result is to convert that portion of a room so treated into a tunnel-shaped reflector similar in operation to that which is the subject of this application.

Fig. 1 is a front view of a form of the tunnel-shaped reflector A, A, A, with the end-screen removed to show the relation of the above-described lamp screen, marked B and having curved upper portion B1, to the illuminant C and the sitter's chair D. A background E and rug or carpet F are also shown. Fig. 2 is an external view of that extremity of the tunnel facing the sitter, showing an end-screen, G, G, G, in position, an opening H being left for convenient access to the interior of the tunnel. Fig. 3 is a transverse section of a room fitted with four portable rectangular frameworks I, I, I, I, having curved inner surfaces, J, J, J, J, covered with light-tinted fabric and combined to form a tunnel-shaped reflector, as described.—Arthur Thomas Jones, 29, Willingdon Road, Wood Green, London, N.

The following complete specifications are open to public inspection before acceptance:—

Film Cartridges.—No. 183,802. Photographic film cartridges and protective leading strips or backings therefor. Kodak, Ltd.

Reproduction Process.—No. 183,817. Photographic reproduction process. E. Doelker.

New Apparatus.

The Azol and Vedol Thermometer. Sold by Johnson and ons, Ltd., 23, Cross Street, Fiosbury, London, E.C.2.

Thermometers are now largely in demand, because of the ever-increasing number of advocates and users of the time and temperature system of development, and the new pattern introduced by Messrs. Johnson has advantages which will be quickly recognised by all those who are in the habit of developing by time and temperature methods. The firm have for many years issued the most helpful time and temperature tables with their well-known Azol and Vedol developers, tables which have many admirers, as they do much to assist photographers to produce a properly-developed negative.

The thermometer has been specially designed for dark-room use, and when not in actual use for ascertaining the temperature of a developing solution it serves as a useful and ornamental accessory for the dark or any other room. The accompanying illustration gives a good idea of its appearance. The thermometer proper is encased in a stand of polished celluloid, which is easily cleaned and not affected by developing solutions. The conical base enables the thermometer to stand perfectly rigid in flat dishes, and is perforated to permit the solution to come into contact with the mercury bulb, which is so low down that the temperature of even very small quantities of solution contained in measures or flat dishes can be easily and accurately determined. Should, however, it be desired to use the thermometer independently of the celluloid stand, the cap at the top can be unscrewed and the glass tube removed for the time being and then replaced.

The scale goes from zero to 120 degrees Fahrenheit, and the boldly printed figures can, if necessary, be read in the usual red light of the dark-room. The mercury tube is housed so comfortably in the celluloid stand, and so well protected by it, that it may be knocked over or packed up without fear of breakage. It is a most useful accessory, one we have had in constant use during the past week, and remarkable value at 3s. 6d. We need hardly say that although issued for use in conjunction with the Azol and Vedol tables the thermometer serves equally well for others, and for all other purposes in which a thermometer is required.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

MONDAY, AUGUST 21.

Southampton C.C. Informal Meeting.

TUESDAY, AUGUST 22.

Hammersmith Hampshire House P.S. Bromoil. J. Iowatt.
Hackney Phot. Soc. Carbro. E. Baldwin.
Bournemouth C.C. Trimming, and Wet and Dry Mounting of Prints. T. O. B. Norman.

WEDNESDAY, AUGUST 23.

Southampton C.C. Outing to Salisbury.
Exeter Camera Club. Outing to Killerton Park.

SATURDAY, AUGUST 26.

Bournemouth C.C. Outing—Lulworth Cove.
Bradford Phot. Soc. Outing to Leathley.
City of London and Cripplegate P.S. Outing to the Inns of London.
Edinburgh Photo. Soc. Outing to Threipmuir.
Hackney Phot. Soc. Outing to Buckhurst Hill.
Partick Camera Club. Outing to Darnley.
Sheffield P.S. Outing to Stoney Middleton.
South Glasgow Camera Club. Outing to Gleniffer Braes.
Willesden Photo. Soc. Outing to Chenies.

SUNDAY, AUGUST 27.

Hammersmith Hampshire House P.S. Outing to Chesham.

CROYDON CAMERA CLUB.

Mr. A. E. Isaac last week gave a lecture entitled "A Paint Box," which resolved itself into a detailed and interesting review of the composition and permanency of pigments used by artists.

Part of the evening was devoted to a discussion on soft-focus lenses. In the opinion of one speaker the prices asked for the majority, if not for all, on the market were simply ridiculously high. It could hardly be contended that the curves of such lenses required any great precision in grinding. Also, their construction was usually simple and the number of elements few.

Mr. Salt pointed out that diffused definition varied not only in amount, but also in character, which, unfortunately, could not be defined in another sense. A professional member of the club, acting on his advice, had recently purchased a long focus landscape lens, working at f/8 for diffused portraiture, and was delighted with the results obtained. Lenses of this type were made in the past by Taylor, Taylor & Hobson, Wray, and others, and are often on the market at reasonable figures. Practical experience in the studio had demonstrated they were relatively fast—quite fast enough for all ordinary purposes—and the deeply recessed single-lens, being protected from stray light, afforded brilliant but softly modelled pictures.

In reference to diffusion devices now largely employed by the separation of elements in normally highly corrected objectives, Mr. Budd said that on testing some both spherical and chromatic aberration appeared. The softening effect of the former could be seen on the focussing screen; allowance, based on experience, had to be made for the latter.

The previous week had no fixed programme, and may be described as "conversensational." Mr. Ackroyd narrated some experiences in Germany. When joining a char-a-banc trip around Cologne a free-lance photographer snapped the party, and had postcards finished on their return in an hour or so. The cards were supplied for 15 marks apiece, at the time equivalent to 1½d. During his visit the mark fluctuated wildly, and in one case, between lunch and dinner, the exchange rate varied 500 marks to the pound sterling.

The subject of "dark rooms" being incidentally raised, Mr Handel Lucas said he was aghast at the conditions prevailing in a few swanking studios. Damp and filthy cellars not infrequently formed the environment of unfortunate assistants during their working hours, whose health was bound to suffer, and sometimes permanently. Only by combination among them, he thought, could this sad state of affairs be altered for the better, for sanitary inspectors were never on the scene.

Mr. Hibbert said he had never heard of a London County Council inspector entering a photographer's. The assistants were "between the devil and the deep blue sea," for the average assistant's place was easily filled. Mr. Berry was of opinion that the assistants themselves were often responsible for the dirt abounding in some dark-rooms. "You ought to see my dark-room!" proudly confirmed Mr. Taylor. Mr. Sutcliffe, he added, had pointed out in the "Yorkshire Post" that the quality of amateurs' photographic work was almost invariably in inverse ratio to the facilities at command.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A meeting of the Council was held at 35, Russell Square, W.C.1, on Friday, August 11, 1922, when there were present Messrs. A. Swan Watson (President), Alexander Corbett, R. N. Speaight, Arthur Bennett, Frank Brown, W. B. Chaplin, A. H. Ll. Chapman, Gordon H. Chase, Tom Chidley, C. F. Dickinson, W. E. Gray, George Hana, William Illingworth, H. C. Spink, F. G. Wakefield, W. H. Wedlake, and H. D. Halksworth Wheeler, with Alfred Ellis (secretary) and Jenkyn Griffiths (Editor of the "Record"). Mr. Alexander Corbett in the chair.

The secretary read various correspondence which had been carried further as a result of instructions at the last meeting. One matter related to the question of fire insurance, as to which he gave particulars of the terms offered to the Association by two companies. Mr. Illingworth proposed that the Council should accept the offer of the Fine Art and General Insurance Company, and should suggest to the members that they insure with that body. This was seconded, and agreed to. The secretary suggested that the commission of 15 per cent., which was allowed by the company on business done with members of the Association, should go, not into the general funds, but into a social benevolent fund for helping any members in time of need. To do this was permissible under the Articles of Association. To the same fund might be allocated any donations which occasionally came to the Association. Some discussion took place as to whether it would be well to call the proposed fund a benevolent or an emergency fund, and it was agreed, on the proposal of Mr. Hana, seconded by Mr. Wakefield, to call it for the time being an emergency fund.

Among the correspondence arising out of the minutes was a letter from a member complaining that he had given an advertisement to a canvasser for a calendar, which proved not to have anything like the circulation promised by the canvasser, and which did not include a photograph which the canvasser had promised to include. On the suggestion of the President, it was agreed that a paragraph be inserted in the "Record" warning photographers against giving advertisements on promises as to circulation, etc., made by irresponsible canvassers.

The secretary reported that he had arranged with Messrs. Cook and Sons to reserve any hotel accommodation which might be required. Mr. Thomas Bell, of Kodak, Ltd., had agreed to send out with his firm's correspondence 5,000 one-page leaflets asking for new members for the Association. The secretary read a leaflet which he had prepared, and it was approved; it was to be attached to the application form for membership. The President proposed a vote of thanks to Kodak Ltd., for their offer, which was seconded, and carried with applause. Mr. Wakefield said that a complimentary ticket for the exhibition would accompany a proportion of the leaflets.

The secretary stated that the Press agent for the exhibtion had received a letter from the Art Editor of the "Times," asking whether there was to be a section for Press photographers, and saying that he would like to exhibit photographs taken by his own staff. The secretary, after ascertaining the opinions of the chairman and others, had replied that there would be provision in the commercial and technical part of the exhibition for a special section for Press photographs, to which the general and illustrated Press would be invited to send exhibits. The Council unanimously endorsed this action and gave authority to the secretary to proceed with the arrangements, including the offering of medals and the appointment of judges, who were to be well-known men engaged in journalism. The secretary also stated that he had got out a special ticket to entitle the professional friends of members to all the privileges of membership of the Congress (apart from the annual general meeting) for a sum of 5s. This was approved, as were some notices to be published regarding the exhibition. A proposal to issue invitations to certain distinguished persons to attend the opening ceremony was left to the Propaganda Committee to deal with.

Mr. Speaight reported that pictures for the exhibition were coming

in at a fairly rapid rate, especially from abroad. Great interest appeared to be shown in the exhibition by photographers in various parts of the world. In reply to questions, he said that work was being accepted as the work of a firm, not of individual members. Space would be found on the exhibition for the proper classification of colour work if necessary. As to what might be included, the governing condition was that everything must have a photographic basis. Autochromes were not acceptable this year, owing to the difficulty of making arrangements for viewing them, but on a later occasion this might be found possible. He also wished to point out that the judges were not the hanging committee; they simply selected the works on which medals were to be bestowed.

Mr. Chaplin reported on the arrangements for the Windsor outing. Lord Esher had graciously given permission for the party to be conducted through the State apartments and for the group to be taken on the East Terrace. The East Terrace was seldom opened to the public, while permission to photograph a group on the Terrace had been given only four or five times during the last 25 years. It was agreed that Mr. Chaplin should take the group from the East Terrace.

Mr. Wakefield explained the arrangement of stands at the exhibition; all save one had been let. He had had 5,000 tickets printed, and the greater part of them distributed among the exhibitors. The secretary also raised the question of the spending of the sum which had been allocated for advertising, and it was agreed that he should see the Press agent, Mr. Somerville, on the question as to the best way in which this should be spent. Mr. Speaight proposed a hearty vote of thanks to Mr. Wakefield for his very exceptional labours in connection with the exhibition. It had meant the writing of innumerable letters, and an immense amount of business; incidentally also, the postponement of his holiday. The vote of thanks was heartily supported from the chair, and equally heartily carried.

The managing Editor reported on the second issue of the "Record," which had been delayed owing to the printers' strike. He also raised the question of publishing a list of members in the "Record"—a list which would cover 16 pages. The secretary suggested that instead of the list being published in the "Record," it should be published separately in a production the same size as the Handbook, and sold to members at a charge of sixpence, which was agreed to. It was also agreed that the names of members be classified according to towns.

The draft report of the Council, record of attendances, and notice of adjourned annual meeting were considered and approved. On a reference in the draft report to the action of the railway companies on the matter of rates for luggage, Mr. Gray wished it made plain that the concession applied to all companies, not to the Great Western alone, although the correspondence had been with them. It was agreed also to add to the attendances of members of Council the fact that a great many sub-committee meetings had been held, and Mr. Wakefield suggested that in future a record of attendances at sub-committee meetings should be kept. These emendations having been made, the President said that a better report could not have been written. It was likely to impress the members and the public with the extraordinary amount of work which was done by the Council.

The chairman raised the question of the reported granting of exclusive photographic rights to a particular firm of photographers in connection with the 1924 National Exhibition at Wembley Park. It seemed to him an unjust thing that this should have been allocated to one firm, apparently without open tender. The concession included also the selling of photographic goods. It was agreed, on the chairman's proposal, seconded by Mr. Speaight, that the secretary should write to the promoters of the exhibition and ask for details as to the photographic rights.

It was agreed to hold a Council meeting on September 1, and another on the afternoon immediately preceding the annual general meeting. The procedure at the Congress was also discussed, in particular the exact programme for the first day, and the President said that he proposed to take as his presidential address the subject of "Some European Portrait Painters, and Some Tendencies in Modern Portraiture by Photography," which would be illustrated.

The secretary indicated, without actually reading, the correspondence in which he had been engaged during the month. It related to such questions as reproduction fees and commercial prices, insurance inquiries, co-operative advertising, collection of debts, copyright infringement, and this by no means exhausted the list. His replies in all cases was approved.

The following new members were elected:—Mrs. Bentley, Miss Taylor, Mrs. Potts, Mr. Fielder, Mr. Hanson, Mr. Cooper, Mr. Birtles, Mr. Davies, Mr. Bain, Mr. Sayner, Mr. Jenkins, and Mr. H. N. Cooper; also one member rejoining, Mr. Puddicombe.

The business of the Council then concluded, having lasted four hours.

Commercial & Legal Intelligence.

NEW COMPANIES.

Ernest H. Mills, "At Home" Studios, Ltd.—This private company was registered on August 2, with a capital of £3,000 in £1 shares (1,500 "A" and 1,500 "B"). Objects: To carry on the business of photographers, miniature and portrait painters, engravers, makers and repairers of and dealers in cameras, enlarging and optical lanterns and cinematograph projectors, picture and photograph frames and albums, film and plate sellers, developers and printers, photograph enlargers and reproducers, dealers in photographic accessories and requisites, art dealers, studio and lantern and other demonstration room proprietors, etc. The permanent directors are: Hon. Mrs. M. T. Phillips-Roberts, 115, Gloucester Place, Portman Square, W.1.; J. T. Phillips-Roberts, 115, Gloucester Place, Portman Square, W.1, actor. Qualification of permanent directors, 100 shares. Registered office: 185, Piccadilly, W.1.

News and Notes.

Eastman Kodak Company of New Jersey.—The directors of the Eastman Kodak Co. of New Jersey have declared quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of $1.25 per share, of no par value, of common stock, payable on October 2 to stockholders of record on August 31.

Houghtons, Ltd., have issued a very attractive window bill or poster as an advertisement of their Ensign cameras and films. The poster, which is beautifully coloured, measures about 30 ins. by 19 ins., and represents the figure of a very pretty girl (in a red head-dress, white jumper, and blue frock, stockings and shoes) carrying an Ensign camera. Any dealer who has not yet received a copy would do well to communicate with Messrs. Houghton.

Historic Lenses.—We are informed that Mr. Will Day has been successful in obtaining for his collection of apparatus relating to the cinematograph industry, which will shortly be on view at the South Kensington Museum, the original Dallmeyer R.R. lens, which was used extensively by Edweird Muybridge in his experiments in connection with the production of a moving picture. Mr. Day has also obtained the first Dallmeyer cinematograph projection lens which was manufactured in 1904.

Mr. H. J. Kraushaar has been elected a Fellow of the Incorporated Sales Managers' Association of the United Kingdom, the election carrying with it the right to use the letters F.S.M.A. Mr. Kraushaar has been advertising and sales manager of the firm of Thomas Illingworth and Co., Ltd., of Willesden, for about twelve years, and a member of the Association since 1913. We congratulate him on receiving this honour from an Association which is doing so much good work in the world of commerce.

Parcel Post to New Zealand.—A correspondent who is attached to the dispatch department of one of the leading photographic firms, writes as follows: "There has been a tiresome restriction concerning the size of parcels that may be sent by post direct to New Zealand, and it has been announced by the Postmaster-General that the restriction is imposed not by the postal authorities, but by the steamship companies which carry the parcel mails on the direct route. Although the dimensions of post parcels sent by the direct route to New Zealand will remain 4 ft. for the combined length and girth, the Post Office has now arranged to accept parcels measuring up to 6 ft. combined length and girth, for conveyance

via Australia, at postal rates that are only slightly higher than for parcels sent direct. The limit of weight will be 11 lbs.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.—We learn from the current issue of the "B.P.S. Journal" that Lieut.-Colonel P. Docker has resigned the hon. secretaryship of the Birmingham Photographic Society, and that Mr. J. E. Breeze, of 178, Broad Street, Birmingham, has been appointed to the post. Mr. Docker was hon. secretary prior to the war, and relinquished office, temporarily, on joining His Majesty's Forces. On his return, when the fortunes of the Society were at their lowest ebb, he resumed the secretarial duties with characteristic energy, and the flourishing condition of the B.P.S. to-day is mainly due to his efforts. Mr. Docker has recently been appointed to the command of the 8th Battalion Royal Warwickshire Regiment, and the duties in connection therewith make it impossible for him to any longer fill the post he has so long occupied with such success.

EMPIRE PATENT RIGHTS.—The report of the conference of representatives of the Patent Offices of the Dominions, which was held in London during June last, has been issued by the Stationery Office, price, post free, 1s. 1d. The conference, which was held to consider the practicability of instituting a system of granting patents which should be valid throughout the British Empire, agreed that a British Empire patent, or, in other words, a patent which would be operative throughout the Empire, would be desirable, provided it in no way affected the autonomy of the Dominions and India, or the rights and facilities which an inventor at present enjoyed in those countries. With this object they decided on a scheme for the establishment of a central office for the reception and examination of applications for, and the grant of, patents. Until it should be possible to introduce the full scheme a provisional scheme was adopted. The conference was of opinion that whether or not the schemes suggested were found to be practicable, it was of the highest importance that both the procedure and practice in respect of the grant of patents should be uniform throughout the Empire.

"OPERATOR" OR "POSEUR"?

To the Editors.

Gentlemen,—I would like to express the great pleasure I had in reading Mr. Effel's treatise on portraiture. After being closely acquainted with many studios of various calibres and styles, I think his dissertation is the best thing I have come across, though I fancy it may give rise to some controversy. All for the good of the profession however.

There is one thing I must comment on. The need for a new term to replace "operator." Might I suggest the word "poseur," meaning one who poses and pronounced like "pozer," but with emphasis rather on the last syllable. This would be more appropriate and sound better than operator, which is only suitable for the man who manipulates the camera. If Mr. Effel, whom I have not the pleasure of knowing, will take up this word, or any other, and use it exclusively in his present series, it may be the means of breaking down the conservative, glued-in position of the unwanted term.—Yours faithfully,

J. R. H.

Liverpool.

SYSTEM IN HALF TONE OPERATING.

To the Editors.

Gentlemen,—Replying to Mr. Bull's letter in your issue of July 28, I appreciate his remarks, and agree with him entirely as to the necessity for further careful work for quantitative results to be obtained, and I would suggest that Bolt Court School is the right place for such work to be carried out.

I have done my best to point the way in which half-tone operating can be simplified, and I consider that there my duty to the trade ends, my own firm having first call upon whatever may be the outcome of my experimental work.

Either I did not explain myself clearly or Mr. Bull has not quite caught the spirit of my article of July 14, when he states that I say that the visual diffraction halo is the *cause* of the difference in working separations with coarse and fine screens. What I have tried to convey is that these halos are indicators from which the difference can be calculated. How this diffraction pattern affects what happens in the focal plane is still to be discovered, and if Mr. Bull, with his greater scientific knowledge, cannot see any explanation, I would not venture at this stage to suggest one. The formation of the dot is a complex problem, and cannot be explained by any simple formula. There are three principal factors to account for, the dioptric projection of the lens, the pinhole image of the diaphragm projected by the screen opening, and the disturbing influence of diffraction at some stage of the operation, and these factors do not all act proportionally throughout the whole scale of gradation.

I have read up everything I can find on the subject, but cannot find anything which accounts for the difference in screen separations, and as the visible halo does provide the missing factor, I am content to make use of it.

There is one thing which reacts for or against progress in any industry, and that is the attitude of the industry concerned, and it so happens that vested interests and tradition are not strongly in favour of progress in the photo-engraving industry. The law of the survival of the fittest will probably solve the problem eventually.—Yours faithfully,

E. A. BIERMAN, F.R.P.S.

THE CAMERA AND THE CUSTOMS.

To the Editors.

Gentlemen,—There have been several references in your pages to the question of what one may or may not do in the matter of bringing cameras, etc., into this country from the Continent in general and Germany in particular.

It may therefore interest you and your readers to know that last Friday, the 11th inst., the Foreign Office issued some warnings to travellers entering or passing through Germany with regard to German laws.

With certain exceptions they may take no articles out of Germany unless they have received export licences for them.

The exceptions are:—

Articles brought by them into Germany.

Second hand articles purchased in Germany and required for use during the journey.

New articles bought in Germany and required for use during the journey.

Travelling souvenirs and the usual travelling presents, valued at less than 1,000 marks. All such articles must be voluntarily declared.—Yours faithfully,

A TOURIST PHOTOGRAPHER.

PHOTOGRAPHING FLOWERS.—When photographing blooms cut from the garden, you oftimes find between focussing and exposure they have drooped quite a lot (says a writer in the "B.P.S. Journal"). Flowers will last longer in water and will not droop if the following notes are followed. Gather rosebuds in the evening, just as they are about to unfold; they will open perfectly indoors next day. Sweet peas keep erect longer and also retain their perfume and delicate shades if picked in early morning before the dew has left them. Many people think Shirley and other poppies will not keep well in water; if gathered first thing in the morning these flowers will not droop and will last quite a time if the ends are charred in a flame before putting in water. It seems a funny treatment, but you need only try it to find how satisfactory it is. Flowers like daisies, such as marguerites, asters, chrysanthemums, dahlias, etc., do not expand well in water; these should be gathered when fully opened and the sun is absent. Gladioli and lilies should be picked in late afternoon. These should not be put into water at once, but placed aside for about twenty minutes, then put into water, and they will pick up wonderfully. Gladioli will last a fortnight and bloom from the bottom bloom right to the topmost point; pick off the spent blooms as they wither.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

S. E. J.—The list price of the Cadett shutter of the size you mention was about 25s. You must base your own selling price on this.

C. B. A.—(1) Our contributor informs us that the lens used was a No. 3a of 8 ins. focus, covering a half-plate; the size of the flange is 1¾ ins.

H. G. W.—The value of the lens in question depends upon its quality. It cost from £8 to £10 twenty-five years ago, and would perhaps fetch half that price now.

Y. A. S.—The amount of iron necessary for a barrel of 25 gallons capacity is said to be 7 lbs., which should be suspended in the centre of the barrel. The greater the amount of surface exposed to the solution the better; that is to say, a plate of iron is preferable to a block, and hoop iron is specially recommended.

B. J. P.—The firm inform us that they are unable to quote for or supply materials for the making of opalines. The process is now out of date, and Fallowfield, we understand, cleared out their stock about ten years ago. We are informed that the materials are no longer obtainable from any source. Why not take up the more up-to-date passe-partout?

M. M.—Your trouble is apparently due to the fading out of the red pigment, which has left the white too prominent. We would advise you to write to Messrs. Winsor & Newton, who are always glad to be helpful in such cases. Rose madder is the most permanent of the pink reds, but it is not by any means safe. The firm would probably suggest colours which would stand exposure to light well, even if not quite so effective at first.

D. J. W.—You can certainly use the ferrotype plates or postcards in an ordinary camera, and the results should be even better than with the special apparatus. The developing and fixing is usually done in one solution, which you can buy ready for use. You hardly require a dark-room, a box with a sleeve so that you can transfer the plate from the slide to the developer which could be contained in a jam pot is all that you would require.

H. H. Y.—If your lens is that originally supplied with the camera it is a cheap single achromatic with an initial aperture of f/10. The numbers of the stops do not agree with any standard system. Generally speaking, we should advise you not to waste money on altering the lens, but to buy a quarter-plate rapid rectilinear in Unicum shutter. This, with a focussing scale and view finder, would enable you to make exposures in the hand.

K. E.—Messrs. Dallmeyer have an instantaneous shutter suitable for a No. 4 Series I Stigmatic, viz., the Packard-Ideal shutter. This is made up to 5-inch opening and can be had time only, say ¼-second and up, or with instantaneous adjustment which would, in the large size, work from about one-fifth to 1-20th of a second. We have had considerable experience of these shutters, and can recommend them as quite reliable. For details of size and price see pages 768 and 788 of the current "B.J. Almanac."

S. C. L.—It appears that your heat is not great enough to get the silver fluid hot enough for all the dross to separate. A method which requires rather less heat is to roast the sulphide on an open pan over a fire until it reaches red-heat and is fused into a smooth mass. Powder this, and to every fourteen parts add sixteen parts of a flux composed of carbonate of potash, 3 parts, and carbonate of soda, 2 parts. Half-fill the crucible with the mixture and expose to a red heat. Pour into an iron mould which has been polished with plumbago.

A. D.—We do not think that brass taps would be detrimental to the solutions, but fear that the hypo solution would be detrimental to the taps. Why not buy stoneware taps, which you could procure from Doulton & Co., Ltd., Lambeth, London, S.E.1. Marine glue, composed of asphaltum and indiarubber, or a mixture of red and white lead in linseed oil, are good cements for the joints; as little of this as possible should be put in the joint before screwing up. The tanks will stand better if they are not varnished in any way. A lead lining is advisable for the hypo.

M. E. T.—You can remove most of the tarnish from the bromide print by rubbing gently with cotton wool soaked in methylated spirit. If you then apply a polish of 1 oz. white wax dissolved in 1 oz. benzole, just as you would polish furniture, it will protect the surface in the future. Of course, any spotting or working up must be done after the spirit and before the wax. Messrs. Eveling & Tress, Ltd., 4a, Rathbone Place, Oxford Street, London, W.1, or S. Bruley & Co., 94, Charlotte Street, Fitzroy Sqnare, London, W.1, will furnish cut-out mounts to order.

G. W.—The most suitable lamps for projection work are the small ones used for motor headlights, as in these the filament is concentrated, but these are only made to work on the low voltages given by the car's generator. We have used 10 ordinary half-watt lamps of 120 c.p. by putting a piece of ground glass as near the lamp as possible; this destroys the image of the filament. If you do not mind the little extra attention needed, the small enclosed "Westminster" arc lamp, which is made specially for lantern work, is highly satisfactory. It is especially valuable for somewhat dense negatives.

S. A.—The change of illuminant has nothing to do with the poor colour of your postcards. This is caused by insufficient development, either by reason of too short a time or the use of a weakened developer. To get a good black development should not be for a shorter time than 90 seconds, the exposure being regulated to suit this time. Amidol developer does not remain active for long after mixing; three days is practically the limit. It is sometimes recommended to keep a stock solution of sulphite and add the amidol as required. This is quite the wrong way, as the sulphite solution will not keep well.

L. T. B.—The tone depends largely upon the quality of the negative and the make of paper used, and we advise a little experimenting with really good negatives and a few different makes of paper. The formula you require is: Ammonium sulphocyanide, 20 gr.; gold chloride, 2 gr.; water, 20 ozs. Dissolve sulphocyanide in half the water, and gold in the remainder. Add gold solution to sulphocyanide solution in ounce lots, and let stand 24 hours, or use hot water when mixing, and use when cold. If your negatives are good and not too thin this toning bath should give the tone desired. Fix in an alkaline hypo bath, and afterwards wash in the usual way. Tone well and allow for the reduction which takes place in the hypo bath.

JOURNAL OF PHOTOGRAPHY.

No. 3251. Vol. LXIX. FRIDAY, AUGUST 25, 1922. Price Fourpence.

Contents.

SUMMARY.

Many useful hints on the avoidance of reflections in framed pictures, spectacles, glassware, silver, etc., are given in a contributed article on page 453.

The semi-metallic tarnish, which is liable to make its appearance on black bromide prints on exposure of the latter to the air of ordinary rooms, appears to be due to a partial sulphurising of the silver image. It can be easily removed with ordinary india-rubber. At the same time the fullest possible fixation of the prints, preferably in two or three baths in succession, appears to be of some benefit in preventing the production of this "bloom." (P. 502.)

For prevention of fogging of plates or papers there is perhaps no more effective means than to isolate the fixing solution in a sink of its own provided with a tap by which negatives and prints, as well as the photographer's hands, can be fully rinsed before they are brought in contact with anything else. (P. 502.)

In a further communication Mr. J. Effel deals with the important problem of spacing and sizing the picture. (P. 505.)

For the development of a large number of plates, some of which may be over- and some under-exposed, a two-dish or two-tank method is of great advantage in saving time and obtaining on the average the best results from the exposures. (P. 502.)

Now that many lantern-slides are being made in anticipation of the winter lecture season, it is appropriate to draw attention to the preventive measures which can be taken against dewing of the slides on the screen. (P. 501.)

In a further instalment of the present chapters on depth of focus there is shown the derivation of the formulæ from which can be ascertained the distance (from the camera) to which depth extends behind and in front of a point which is sharply focussed when using a lens of given focal-length and working aperture and when adopting a given diameter of disc of confusion. The formulæ assume a somewhat simpler shape when the disc of confusion is taken as a certain small fraction of the distance from which the print or enlargement should be viewed. (P. 507.)

We look with suspicion on the offer for sale of secret formulæ, and in a paragraph on page 501 suggest a test to which a vendor of a genuine formula could scarcely object.

Some novel methods of displaying cameras with the idea of increasing sales during the autumn will be found on page 508.

The renovation of Daguerreotypes and many other matters are dealt with by writers in our "Correspondence" pages. (P. 513.)

EX CATHEDRA.

Dewing of Lantern Slides. The approach of the autumn season, with its arrangements for lantern lectures in the winter, may be our excuse for referring to the need of greater care than appears often to be taken in preventing the dewing in the lantern by which so many exhibitions of slides are disfigured on the screen. It still appears to be thought by many lanternists and slide-makers that this dewing is caused simply by condensation of moisture on the outside of a cold slide when the latter is placed in the warm stage of the lantern. Hence it is thought that if slides are warmed beforehand all will be well as regards the absence of dewing on the screen. But our experience is that dewing arises within the slide from the presence there of a damp gelatine film. It will be found that slides may be warmed above the temperature of the lantern stage, and will still dew, whilst, on the other hand, they may be colder and will still scarcely dew at all. The latter condition is obtained only when the film is perfectly dry, for which reason the slide-maker should take particular care in this respect when mounting them with their cover glasses, and preferably should varnish them. Cold varnishing (after the slides have been baked bone dry) is now so conveniently done that there is no reason for avoiding it. The mask also should be dry, which is an argument against the use of masking strips, applied with a moistened adhesive, instead of a single cut-out

* * *

Formulæ Mongers. It is difficult to find anything good to say of the practice of offering for sale secret formulæ for some photographic process. If the formula for, say, a toning solution or a fixing bath is offered on the customary terms that the purchaser shall not disclose it to anybody, a reasonable inference is that the preparation is not worth putting on the market for sale on its merits. For the financial return from the sale of a formula must usually be very small compared with that from the supply of the preparation itself, assuming that the latter has real merits to its credit. In our experience formulæ are sold chiefly to the ignorant and undiscriminating, and that is not surprising, since the opportunity for fraud which is within the law lies so ready to hand. It should be realised that a formula which is offered at a price from a few shillings to many pounds may be found in substantially identical form in many of the text books. In some cases it may differ from existing and well-known formulæ for the same purpose by the inclusion of some uncommon chemical, the presence of which, however, is entirely without effect. The vendor supplies what he offers, and if people are silly enough to accept his statements on his own valuation, the law, unfortunately, does not provide them with a remedy. It may perhaps be thought that the offering of formulæ for a few shillings is a minor and harmless

species of trading which does not justify such cautions as we have just written. But within the last twenty years cases have come under our personal observation in which formulæ have been sold for a sum aggregating hundreds of pounds, yet have proved completely useless to the purchasers. In considering such offers where any substantial sum is at stake there is one course which should invariably be taken. Let the vendor be asked to submit his formulæ in confidence to an agreed independent expert, with the request that the latter shall answer the questions: (1) Is the formula substantially novel? (2) If so, is its novelty of any advantage? and (3) Is the formula of probable commercial value? If the offer is genuine, the vendor cannot reasonably object to this course. If, on the other hand, money has been paid for a formula which proves to be valueless for one reason or another, resolute legal action will sometimes bring the vendor precipitately into a subdued frame of mind. The publicity of the County Court is the last thing the formula monger desires to obtain.

* * *

Hypo Infection. We are afraid that the text books do not go far enough in their cautions against allowing hypo to stray from its proper place in the dark-room, namely the fixing bath. We are very properly told to avoid splashing hypo solution into the fixing bath, but where a large output of negatives or prints is handled, often by assistants of none too meticulous habits, it is necessary to arrange matters so as to make that almost impossible, and also to induce a method of working which removes the opportunities of contaminating the developing with hypo. The item of equipment of the dark-room, which is of chief importance in this respect, is a sink of ample size to accommodate the fixing baths; a sink, moreover, provided with tap and waste pipe so that negatives or prints may be rinsed from the fixing bath. This sink should be a few feet distant from the developing dishes, and it is all the better if the space above part of it is screened off by a pair of partitions. A diffused white or light yellow light within this shelter thus allows of the density of negatives being judged without scattering hypo droppings on the developing bench, as must be done if only one lamp is available in the dark-room. In short, once negatives or prints have entered the fixing bath, the next and only convenient route for the surplus which adheres to them on removal from it should be down the waste pipe of what we may call the fixing sink, with the help of plenty of water. Under these conditions it should be difficult for the careless to scatter hypo in those parts of the working space where it ought not to come. A further merit of the arrangement is that the hands may be freely rinsed from hypo and the dark-room towel kept for its proper purpose of drying. Too often it is simply a mopper-up of hypo and a distributor of this chemical to everything which afterwards touches it.

* * *

Two-Solution Development. The practice of developing by time for a fixed period has gained so firm a hold during the last few years that one may assume the existence of a younger generation of photographers among our readers to whom the many past methods of "tinkering" with the developer are unknown. Just as well, perhaps; more correct exposure, greater latitude of plates, and printing papers for negatives which formerly would have been scrapped have done their work, so that the cherished methods of, say, ten years ago tend to be entirely forgotten. Nevertheless, it may not be without advantage to bring to the notice of the holiday-maker who has returned with, may be, some dozens of exposed plates, the advantage of a method of development which goes far to compensate for errors of judgment in exposure. Briefly, the method is to provide two grooved tanks of developer, one containing a weak developing solution of the kind which brings up detail quickly and density more slowly, and the other one which in these respects is the opposite of the first. It is easy to judge from the appearance of a plate after a few seconds in No. 1 if it had better be left where it is to receive the best treatment for under-exposure, or, alternatively, should it come up quickly, if it should be transferred to No. 2. If the fault has been over-exposure, plenty of time in No. 2 will make the best of it. There is no magic in the choice of the formulæ for the two solutions. We have used 1:30 Azol for No. 1 and an ordinary pyro-metol developer for No. 2 with much satisfaction.

BLOOM ON NEGATIVES AND PRINTS.

THE lasting qualities of properly made prints on emulsion development papers may reasonably be said to have justified in course of years the name which was applied at about the time of the introduction of this class of paper, namely, "permanent bromide." So far as fading from internal causes is concerned, there is no reason to regard developed bromide or gaslight prints as other than highly permanent, so long as fixation has been thorough and washing ample. If these conditions are observed, about the only form of deterioration which such prints undergo is one which arises from the circumstances in which they are kept, and takes the form of a semi-metallic sheen, particularly noticeable over the surface of the darker part of the image. This defect is sometimes spoken of as "oxidation," but it is almost certainly a form of sulphurisation arising from a partial sulphiding of the silver image by traces of sulphur compounds in the air to which prints are exposed, or in, for example, paper with which they lie in contact. The sheen, in fact, corresponds with the tarnishing of silver, which is noticed in the case of ordinary articles of domestic use composed of this metal. From the fact that in a bromide or gaslight print the silver image is held in a coating of gelatine, the film of sulphide which thus forms in the course of time is superficial, and can be readily removed by rubbing. Ordinary indiarubber serves to clear it away with reasonable ease, leaving the print practically in its original state. A mildly abrasive preparation, such as that sold as "Frictol" by the Vanguard Manufacturing Co., serves the same purpose as well, if not somewhat better. Uranium-toned prints are particularly susceptible to change of this kind, and the prevention of the bronzing in their case, as well as in that of an untoned print, by the application of a thin coating of celluloid varnish, shows that the defect arises from some action of the air, and not from decomposition within the print itself due to faults in its production.

Nevertheless, the processes used in the making of the print, or rather the degree of perfection with which they are carried out, do appear to have some effect in the occurrence of this bloom in the course of time. In the case of a number of prints made on the same paper on different occasions, some, in our experience, have exhibited the appearance of the bloom, whereas others have been free from it. So far as we can judge, the cause for these differences is simply the degree to which a print is "completely" fixed. We say "completely," because it would seem that when the fullest degree of fixation has been carried out, there still remains a minute residue of silver (other than the silver image) in the

print, and it is the quantity of this residue which determines the greater or less time which may elapse before a print exhibits this semi-metallic sheen under given conditions. It should be made clear that we are not referring here to fixation which in the ordinary way could be called incomplete, that is to say, such fixation which would leave readily decomposable hyposulphite compounds of silver in the print. Such incompleteness of fixation makes itself evident within a very short time by the occurrence of brownish or yellowish patches, the ordinary fixing stain. But, on the other hand, more can often be done than is commonly the case in the handling of fairly large batches of bromide prints to remove the last traces of silver which are removable by hypo. In the early days of bromide paper the common practice was to use a single 10 per cent. solution of hypo for fixation. Of late years the tendency has commendably been in the direction of the use of a much stronger fixing bath, 25 per cent. or 30 per cent., and, moreover, the use of two such baths in succession. In our opinion this ultra-full fixation is well worth while, on account of the greater degree of immunity from the bronzing with the lapse of time, although this latter seems inevitable if sufficient time is allowed and if the ordinary conditions, *e.g.*, exposure to air, apply to the circumstances in which the print is kept. There are, we know, many photographers who now religiously pass prints through two and in some cases through three fixing baths in succession. So far as the immediate permanence of the prints is concerned, they are no doubt doing more than is really necessary, but they may be assured that this meticulous care is not wasted from the point of view of producing prints which shall retain their pristine quality unimpaired for a long term of years.

ON THE AVOIDANCE OF REFLECTION MARKINGS IN NEGATIVES.

Reflections of surrounding objects are the bugbear of the commercial operator. More or less distinct images, usually much distorted, of studio and camera are to be seen in every curve of polished objects. Shop-windows often are a source of great tribulation. The copying of pictures, whether under glass in a gallery, or oil-paintings with their varnish and projecting lumps of shiny paint, is another case in point, as is the more familiar copying in the studio or workroom of semi-matt prints, or of glossy ones which will not lie flat.

In this latter work the writer regrets to state that he has many times seen assistants in great trouble with reflections even in prints which are perfectly flat, and this fact is due to the very happy-go-lucky, rule-of-thumb methods of training (?) which, unfortunately, are still very common in the profession. Even the studio portraitist experiences difficulty at times with the sitter who wears glasses, while in a great many subjects that come before the camera there are less noticeable reflections which mar the result, while not making the source of the degradation so obvious as in the cases specified.

There are cases where reflections are absolutely unavoidable, but in the vast majority of subjects they may be either avoided or modified so as to render them less objectionable. In some cases the reflections may be made to improve the result, and those in which nothing at all can be done in either direction are very few indeed.

It is the object of these notes to show how the source of the reflections, not always very obvious, may be easily discovered, and, having found the origin of the trouble, how to remove or to modify it according to the subject in hand.

It is so easy to dismiss the whole question with the axiom that "the angle of reflection is equal to the angle of incidence," but in practice that principle can be used only in a very rough and ready way, and when one is handling objects containing many curved surfaces it is no help at all. Let us first take the simplest case of all, that of copying from a flat print pinned on the copy-board. Patches of brilliant "grain" are seen in the negative that may not have been noticed on the ground-glass. For one thing it is poor economy to employ glass so coarsely ground that a fault of this kind cannot be instantly recognised. A new focussing-screen is cheaper than a couple only of spoilt plates, to say nothing of the time spent in repeating the job. These shiny patches are nothing but reflections of the source of light broken up by the texture of the print itself. While obviously the light must shine upon the print in order to illuminate it for photographing, there is no reason at all why these patches should ever occur. In order to avoid them it is necessary first of all that the camera should be always quite at right-angles to the copy-board and to arrange the lights in such positions that their actual images will never be reflected from any part of the board into the lens. Having determined this position by the means about to be described, the lights must be either permanently fixed or some arrangement must be made whereby the conditions may be exactly repeated at any time. To discover the proper positions for the lights—really quite a simple matter—it is advisable to insert a fairly short focus lens in the camera which then is focussed so as to include the whole board on the screen. The lens and the focussing-screen are then removed from the camera. The lights having been arranged at such a sufficient distance from the board as to illustrate it evenly, a mirror is held by an assistant flat against the copy-board, while one looks through the camera from behind. In the middle of the board nothing will be seen in the mirror but a reflection of the camera front, but on moving the glass towards the margins of the board one may observe the image of the light itself at some point or other. When this is so, the lamps should be moved outwardly in a line parallel with the board until their images can no longer be seen in the mirror wherever this may be placed (always keeping it flat against the board, of course) from any point at the focussing frame of the camera while looking at the board through the latter. If the lights are then screened so that the camera front itself is not sufficiently illuminated to cause a reflection to be seen, no trouble of the kind described will ever occur, unless a print to be copied is buckled in any way. In such cases as this a refractory print may be placed in the dry-mounter for a few seconds to flatten it. If it has become creased, and has not been mounted, the trouble may be overcome by well wetting, and by putting down upon glass in the case of glossy paper. If, on the other hand, it is a matt print, it may be laid face up, after soaking, upon a waste piece of glass, and having drained a little while, strips of gummed paper may be stuck down all round it, just catching the margins of the print. In drying the paper will try to contract, and it will dry perfectly flat and in good condition for copying. If the surface must not be wetted, the same result may be gained by repeatedly moistening the back with a wet brush or sponge until it is limp.

The next problem chosen because of its similarity to the

foregoing, is that of copying pictures under glass. It happens frequently that a picture is considered too valuable, or the time is not available, to remove it from the frame. If one can place the whole thing on the copy-board arranged under the conditions just laid down all will be well, providing that the area to be copied is not larger than the copy-board provides for. These fortunate circumstances, however, seldom fall to the lot of the photographer. The underlying principle is precisely the same, but the means to achieve the desired end differ, for the simple reason that while in the first case we were able to fix our lights conveniently, here we must take our lights pretty much as we find them. If there are windows on two adjacent sides of the room, with a dark corner between which the picture can face, then the conditions approximate very much to those laid down for a copying installation. It is rather rare, though, to find circumstances so favourable that it is possible to place the picture just as one wishes, and usually one has to be satisfied with a single source of light. Usually, however, this is sufficiently large to permit of its being split up into two by a fairly large black curtain, which is supported so that the camera is behind it and the lens peeps through a slit in the centre. This slit should be provided with a few dress-fasteners, so that it can be well closed round the lens. A peculiarly shaped dense spot on a negative may be traced to a part of such a slit being left open so that a little light crept through over the top of the camera. In fact, it has not been unknown that a bit of the red focussing cloth showing through such a curtain has been registered on a negative when (as always should be in picture copying) a panchromatic plate was used with a deep filter. People who do not trouble about such a thing as a black curtain are seldom troubled either with such markings, for the simple reason that their negatives have more or less haze from reflections all over them.

How a curtain for this purpose should be held up is a matter for individual circumstances, as well as for individual ingenuity, as it should in any case be rather larger than the subjects to be photographed, and considerably so if some distance is maintained between subject and camera. The writer has often been amused by seeing an illustration of such a curtain being held up in the manner of a banner by two men supporting a pole on either side with the avowed object of preventing reflections in a shop-window. Apart from the strictly commercial aspect of the case, that the price for a shop-window photograph seldom, if ever, permits of the transportation of two large poles and the time of three men, the technical point that makes the idea so futile is that a screen sufficiently large effectively to prevent reflection in any shop-window must be at least four times its area. Certainly, any attempt at using such a curtain would instil an element of sport into a very dull business. A window that is dressed with dark goods, and has buildings of a light nature opposite, is pretty much like a mirror, and reflections are practically unavoidable. As regards the goods, the proprietor often arranges a special display for photographing, and if a word can be got in beforehand it may be suggested that the contents should be kept as light in colour as possible, and also well forward towards the glass. If the latter has had the quite recent attentions of the window-cleaner a noticeable improvement in the quality of the photograph will be effected.

Even as regards the buildings opposite the shop-window the photographer is not entirely helpless. Sometimes a standpoint a little more to one side or other avoids certain details, but there is one very helpful thing the operator can do. That is to discover the time when the sun will not be actually shining on the shop in question, but when either it is nearly upon it, or has just left it. It must be obvious that if the strongest light shines on the opposite buildings the very finest set of reflections imaginable will most certainly result. The more one can get to having these details in shadow the better the photograph will be. A method of finding out the time of day required was described by me in the "B.J." and the "Almanac" a few years ago under the title of "Sunshine Index." The most unreliable means of discovering the required information is to ask the people in the shop. Strange, but true. When the training of observation is made a school subject, in place of mere accumulation of second-hand information, such a difficulty should no longer obtain.

I mentioned the case of the portrait artist who has a sitter wearing glasses. Many light studios give trouble in the form of haze over the lenses obscuring the eyes. Some operators make a practice of removing the glasses from the frames, but this plan has two objections to it. The first is that the sitter is apt to wear a strained expression when without the glasses to which he is accustomed. The second is that the detail of the eye is apt to look over-sharp. In a successful result taken normally, there is the natural expression, in addition to the eyes as one sees them through the glasses; it may be the least bit larger than life, and there is a tiny glint on the bevel edge of the lenses which shows that a glass is there. Unnoticeable details, perhaps, but the effect is quite distinct. Now except for extraordinarily curved lenses, the solution of the problem is simplicity itself. It is the same method as is used for glazed pictures. A focussing cloth hung over a head-screen or just held by an assistant in the direction the sitter is looking, wherever that may be, will be efficient prevention of all objectionable reflections. In any case one can observe the effect by looking over the camera just before exposure, so that there is no chance work about it.

When we turn to the question of polished articles the case is somewhat different. If we erect black curtains to cut off reflections the result most probably will be turned down with disgust. The black screens will show as black patches in the polished surfaces of the subject, and the larger the screens the blacker the article will look. Now polished articles should be represented as brilliantly as possible, and if it be glassware or silver they should look white, and not black. Hence in these things we actually need reflections, but not merely mirrored images of the room and its contents. Hence for this class of work it is desirable to employ quite a big area of diffusing material, as well as of reflecting surface. In fact, many who specialise in this work go so far as to construct miniature studios of diffusing material such as muslin, or even of tracing cloth, so as to get a continuous reflection, and so show the contours of the object to perfection. Such reflections as are the result of part of the subject showing in a polished surface of the same item, such as, for instance, the handle of a loving-cup, cannot be prevented, except by the expedient of airbrushing a coat of light grey paint all over. This method gives a very beautiful result, if done properly, but is quite a piece of work to do, and never gives the impression of polished silver as a natural photograph does. However, if the photograph is for the purpose of making a process-block, it is quite a good plan, and is certainly cheaper than making an "ordinary" photograph, on which the process-artist has to expend quite a lot of time and skill.

We must treat now of commercial subjects in which objectionable reflections are liable to occur. These are simply legion. Almost every article which one may be called upon to photograph has some reflecting, or semi-reflecting, surface. Take the parts of a typewriter, for instance. A polished bar reflects the details of a room just as the silver cup did, but instead of these being recognisably distorted, they are spread along the full length of the bar in lines of black and white. The process artist transforms these into a beautifully gradated round or square bar, as the case may be. Then we have the enamelled black base and case. Not only do the same remarks apply, but I have found many people quite astonished when I have shown them that a surprising amount of objectionable reflections in many polished articles, including furniture, arises not from the windows or other details that may be in front, but simply *from the white background behind* which is so very frequently demanded by clients. It is far better

to employ a medium tinted ground, and to block out the negative, than to photograph any polished subject of the kind against a white one, and rely on the very expensive labours of the process-artist to make a satisfactory result. It should prove a good business proposition to demonstrate to clients that a shilling or two more spent on a photograph can easily save several times the amount in process work. Block-makers naturally encourage the employment of their "art" departments, and so the worse the photographs supplied the more profit they make. Hence many manufacturing firms seem to regard photography as only a poor sort of basis for afterwork, so that the lower the price the better. It is surprising, too, how some of them resent the time and trouble which the operator takes to secure his results in the rather peculiar conditions often provided, till they see the improved results obtained. There seems to be room for a good deal of propaganda by photographers along these lines.

These latter remarks may seem to be going off the point. When analysed, however, the improvement in results will be found to consist mainly, if not wholly, in the handling of reflections, their avoidance or their modelling into shape. An article of this subject would not be complete without a reference to the virtues of "pan" plates and filters in curing reflections. The major portion of the light shown in the form of objectionable lights or haze on the surface of polished or half-shiny surfaces, including the very objectionable result often seen in negatives and copies from prints of the "satin" class consist of ultra-violet impressions. By "cutting-out" this light one succeeds in getting an image of the detail that lies underneath this shine, whether it be the gradations of a print, the grain of wood, or some delicate engraving on metal, which may have become swamped by the amount of reflected ultra-violet.

D. Charles.

WITH A PORTRAITIST IN THE STUDIO.

VI.—SPACING AND SIZING.

In this country the usual plates in use are half-plates, whole-plates, and larger sizes, and it is customary to make portraits which approximate to these sizes. In serving the public, we are thus enabled to use terms which convey definitely the proportions of our photographs without mentioning exact measurements. While no doubt it is difficult to break away altogether from the traditions of size and shape, one is often hard put to it to make a harmonious composition fall within the space demanded by a stock mount. I believe firmly, however, that the public will welcome unusual pictures which have sound reason behind them. Take a case which I had a few weeks back. I had to go to a military barracks, where I have done a lot of work, to take a group of over a hundred men. For that work whole-plate and 15 by 12 are my standards. Since the conclusion of the war I have never had a really large group requiring a "Cirkut" camera, and I tried to get this group to take bigger than whole-plate. But they were only "Tommies," and wanted "something like that" (indicating a military group of about a dozen men) at a small figure. Well, I took my group in the best accepted method of the old professionals. I built them up in five rows, and crowded them to get the biggest possible figures. Still, when the negative was developed, a picture 8 by 2 inches showed all the soldiers and the rest was courtyard and barrack wall. I hadn't bigger paper in stock than 15 by 12, but I had a brain-wave. I enlarged the group on to a six-on postcard strip, dry mounted it tastefully, and submitted it with the orthodox whole-plate. I made a quotation for six dozen copies; it was ordered right away, and will serve me as a standard for future groups of a similar nature. The small man who gets an occasional order like this will find this a good substitute for a "Cirkut" group.

With studio portraits, we have no great difficulties in this respect, and when we look at the great variety in design and colour of modern mounts for cabinets, it will be seen that we have travelled somewhat from my young days of the black or white g.b.e. mount, common to all photographers, and which was ordered in lots of 10,000.

Yet, when all is said about shaping each set of prints differently to suit the picture, we must realise that it is well-nigh impossible to run a big business, unless the great bulk of the work conforms to a standard size and shape.

There is nothing for it, then, but to plan out our pictures in terms of definite shapes. The man who uses postcard plates is generally cleverer at sizing and spacing than many in a better way of business, for the simple reason that there is no latitude, print and plate being the one size. For all-round work in the studio, busts, full lengths, and groups, the half-plate is of fine proportion. We all know the great difficulty in getting the public to take cabinets, when postcards are on offer. Now, it's no good fooling the public: you can't give them six postcards for 3s. 6d., and grumble if they won't pay 21s. for the same thing mounted on a large folder, and called a cabinet. I am not here discussing the question of postcards *versus* cabinets; I merely wish to point out that the photographer's own foolishness, and in many cases his meanness, has given the public the impression that the only difference between the two pictures is the mount. I will discuss sizing and spacing firstly from the standpoint of selling the goods, and then from the artistic side.

We all know that artistic value cannot be measured by inches or feet. Still, whether we like it or not, most of our work is bought and sold "by the yard," as the stickyback merchant puts it. I remember having just finished an exquisite tinted miniature of a pretty child, and I had it on view in the reception room, before sending it home. When my assistant told me she had three inquiries for the price of the coloured photos "per dozen," I withdrew the exhibit. Unfortunately, the artistic soul of the people is big—20 by 16, in fact. Now, when that is so, and the postcard is a serious menace to the man whose work is worth more than a few shillings per sitting, why do we see so much of the "small cabinet" work about? And again, when we habitually use half-plate size and mounts that accommodate 6 by 4 prints, why do we still do pictures, which would not suffer if trimmed down to postcard size? The answer is that of Dr. Johnson to the lady who asked why a certain word was not in his dictionary. "There is only ignorance to account for it," he said.

Many studio cameras have a focussing screen larger than the size of picture in everyday demand. We have something of the 20 by 16 mentality ourselves. Think of the huge cameras in galleries, where it is an event to expose a half-plate! Few of these focussing screens are lined off properly, and most of them look like a railway junction. I would lay down the rule that only as much of the focussing screen should be seen as will give the exact size of the finished print. The fact that a "cabinet" is considerably smaller than a half-plate is responsible for mistakes in sizing. "Get the picture well within the half-plate lines" is the usual formula, and the new girl printer is allowed to use *her* discretion as to where she places the paper. That doesn't strike me as a method to produce uniformity of output. Those photographers who have difficulty in getting cabinet orders should try a set of specimens taken full half-plate, and see how much more imposing they look than postcards. There is a very

great difference between a picture 6 by 4 and one 5 by 3, and if, consciously, the one is taken small and the other as large as possible, the difference will be all the more noticeable. I suggest that a cabinet picture should (particularly with groups) be taken so that it is impossible to get a postcard from it without copying down.

Don't run away with the idea that I want you to make extra large figures for cabinets; it is largely a case of spacing. Take the orthodox group of two, one sitting, one standing. To get that nicely into a postcard, three inches is all the width allowable to give a little for margin. Well, even with the same grouping, it is simple to widen out the picture, so that it needs four inches to cover the interest. I have frequently seen customers actually measuring an alleged cabinet with a postcard, but I have never yet come across one who could see where a picture taken as a cabinet might just as well have been squeezed into a postcard. The measurement test is the one to convince the public.

Economic considerations apart, the spacing of the picture between its four lines, the consideration of the size of the head in bust work, the use of vignetting as an adjunct to composition, are factors which must be taken into account by the artistic worker.

A full length is probably the simplest portrait to space. Everyone knows that the figure is centred, and slightly more head room is left than under the feet. Ordinarily, a full-length gives no index to the height of the subject, and if it is wanted to convey an impression of size, there are recognised ways of doing this. Keeping a low camera, and getting the head higher up the plate than usual, are two ways of giving a small person dignity. If I were taking a small man, all done up with his new robes of office, I would take good care to make the most of his "little brief authority." If furniture came into the composition, I would see that the pieces were of small size. A high-backed chair and a little man should not be photographed together. When we reflect that most of the world's great men have been of small stature, it is peculiar that, somehow or other, dignity and importance instinctively suggest tall, classical figures to our imagination. It may be the sub-conscious working of the 20 by 16 mind, but, whatever the cause; and despite its utter unreasonableness, no one likes to be thought small, unless it is an asset, like the figure of Little Tich. No very hard-and-fast rule can be laid down governing the placing of the figure between the two vertical outlines; so much depends on the position, and, after all, there is much of caprice or fashion to be considered. It is generally recognised that there should be more space in front of the head than at the back, to avoid the impression that the figure is walking out of the picture. While this is more or less of an axiom for any portrait, I submit that, for ordinary good everyday portraiture, nothing other than taste is required for the harmonious setting of a full length. So much, as I have said, depends on the position, the subject, and the general scheme of the picture that it is impossible to dogmatise. A lady bending over a bowl of roses, a child leading a toy horse or pushing a wheelbarrow, a dancer with outstretched limbs, are all problems in spacing which must just be settled as they come up. A splendid plan is to make a cut-out mount and experiment by placing over your favourite pictures, observing the effects of different settings. All these ideas of sizing and spacing should be worked out in practice, so that there is never any uncertainty with a sitter. A picture accurately placed on the focussing screen will give a negative that leaves no problem for the printer or the girl who trims for the mounting machine.

There is a craze at present for some rather freakish heads, due, no doubt, to the influence of cinema favourites, in their search for novelty—heads falling out of the picture, looking round corners, and other "jazz" styles. Fashion plays a much greater part in the success of photographic portraits than most of us think. I remember the sneers of a stodgy old professional when a rival advertised that he had just returned from Paris with all the latest styles, and was now showing *the very newest positions*. But the sneers did not alter the fact that the pushful one did postcards much smarter than his competitors (and always dearer, too), and made a fortune. Just as the theatre-going public are keen for a while on the "Bull Dog Drummond" class of drama, so are our clients for "the newest positions." I would say this as a word of caution to those who would cultivate jazz in portraiture, or novelty in placing the figure: always make your deviation from the usual palpable. A print just a trifle to one side, or a head slightly tilted, may suggest carelessness, but with a very decided departure it is impossible to be mistaken about the intention of the artist.

The almost general adoption of the use of vignetting in front of the lens has proved of great service in selection, and enables one to modify bust and three-quarter lengths very considerably. Hitherto, one had to take the figure big to cut out unpleasing parts, or vignette the print, and this was not suitable for dark backgrounds. Now, however, it is a simple matter to take the figure as small as may be wished, getting rid of the useless bits by the judicious use of a vignetting card which harmonises with the general tone of the picture. In skilful hands—and there is very little to master—the vignetter is a tremendous help with difficult sitters. With an ordinary type of picture, a bust looking to the front, a simple three-quarter length or small group, it is merely the corners which require to be vignetted, but a word or two about very definite changes which may be brought about by the application of a little method may be welcome. I draw your attention to three little sketches representing different aspects of similar objects.

Fig. 1. Fig. 2. Fig. 3.

In the first illustration (fig. 1) the "building" may stand itself, but, if requiring assistance, the supports would be placed as shown. In the other sketches (figs. 2 and 3), the object is falling, and there can be no question of placing the support. I have indicated by dotted lines how to vignette pictures where the positions bear some analogy to my illustrations. Modify my ideas as you will, get hold of the guiding principle, and you will always be working in the right way; always give more support by leaving more of the figure on that side where the weight predominates.

In the first picture (fig. 1) the head would be centred, and if vignetted, both sides would be treated alike. In the case of a profile (as in fig. 2) there should be more space in front of the head, and vignetting mostly at the back of the figure. For the three-quarter pose (fig. 3) the head may be exactly in the centre, as showing more space in front of the eyes, *never the other way about;* vignetting may be as in fig. 1, or take off more on the opposite side to the support.

Much of our work in the studio seems to be taken up with efforts to make thin people look well developed, fat sitters look normal, and to give the appearance of height to those lacking in inches. It has been well said that "the normal is quite abnormal," and our daily studio experience bears that out. But, the greater deviation from the "normal," the more earnest seems the desire to approximate to the average. The vignetter is a great adjunct to the flatterer. Take a short stout woman. She wishes to be taken three-quarter length standing. We must not take her "too near the camera," so we have to focus the figure on the small side, which, before vignetting, will look like a big full length. Well, then, just vignette her skirt *as near the ground as possible,* and, although you know that the skirt finishes exactly

where the indefiniteness begins, the eye takes the impression that there is much more of the subject cut away. If the spacing is good, the figure rather high on the plate, the arms and lines kept in a downward direction, the portrait should be successful. In a bust of the same subject, if the body is turned away from the camera, the near arm and shoulder can be treated very drastically, reducing the bust to a pear-like shape. If the student will take some little trouble over these problems, experimenting along the lines I have suggested, exposing an odd plate or two on the same subject treated differently only in the matters of spacing, sizing, and vignetting, making and filing prints of good and bad examples, he will find his work considerably enhanced, and, in studying the portrait work of masters, he will be enabled to see how many effects are produced which formerly were beyond his comprehension.

J. EFFEL.

THEORY AND PRACTICE OF DEPTH OF FOCUS.

III.

[Following the formulæ and practical significance of hyperfocal distance, which were the subject of the second of the present series of chapters, the present paper shows the derivation and application of the formulæ for the nearest and furthest distances from the lens to which depth extends when focussing sharply upon a given distance with a lens of given focal length and diameter of stop. It is also shown that, in accordance with the view that the admissible disc of confusion should be a small constant fraction of the distance from which a print or enlargement is viewed, these distances of nearest and furthest focus are independent of the focal length of the lens. In Chapter IV. we shall come to the formula for ascertaining the distance on which to focus in order that depth may extend to given distances further from and nearer to the lens; also the formula for the stop which is required under these conditions if the permissible unsharpness is to conform to a chosen standard. From the standpoint that the admissible disc of confusion may vary in proportion to the distance from which the photograph is viewed, these formulæ become much simpler. Chapter IV. will also explain the basis of a series of distances on which to focus such that, when focussing on any one of them, far depth extends to the next larger and near depth to the next smaller, that is to say, the distances which are the basis of depth focussing scales.]

Near and Far Distances to which depth extends when focussing on a given distance.

In fig. 7 an object at distance u is focussed so that its image is formed at P at a distance v from the diaphragm.

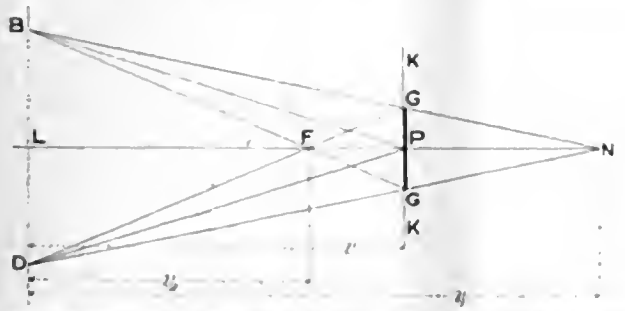

Fig. 7.—Illustrating images F and N of furthest and nearest objects to which depth extends when focussing on a given object.
P is the point of the object in sharp focus. F is the image of the further object and N of the nearer, the cross-section of pencils from each being $G\,G = c$ in the plane of the focussing screen $K\,K$.

If now an object is at such a *nearer* distance u_1 that the pencil of rays, coming to a focus at N, has a cross-section in the focussing screen equal to $G\,G$, the maximum circle of confusion, u_1 is then the nearest distance to which depth extends.

Similarly, if an object is at such a *further* distance u_2 from the camera that the pencil of rays, coming to a focus in F diverges to the diameter $G\,G$ in the focussing screen, u_2 is plainly the furthest distance to which depth extends.

In the diagram, N and F are thus the foci of objects at these nearest and furthest distances and v_1 and v_2 are the distances of these foci from the diaphragm. This construction in the image space enables us to obtain the formulæ for the near and far distances u_1 and u_2.

As before we denote the diameter $G\,G$ of the circle of confusion by c: the diameter of the stop by d and the focal length of the lens by f.

Near Distance.

In the similar triangles, $B\,N\,D$ and $G\,N\,G$,

$$\frac{L\,N}{P\,N} = \frac{d}{c}$$

But $P\,N = L\,N - L\,P = v_1 - v$.

Therefore $$\frac{v_1}{v_1 - v} = \frac{d}{c}$$

or $$v_1 = \frac{dv}{d-c} \qquad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (a)$$

Now the image distances v and v_1 according to the law of conjugate foci, may be expressed in terms of the respective object distances and focal length of the lens, that is:—

$$v = \frac{fu}{u-f} \text{ and } v_1 = \frac{fu_1}{u_1 - f}$$

If these values of v and v_1 are substituted in equation (a) we get:—

$$\frac{fu_1}{u_1 - f} = \frac{fdu}{(u-f)(d-c)}$$

Whence $$u_1 = \frac{fdu}{fd + c(u-f)} \qquad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

This rather complicated formula for the nearest distance to which depth extends may be put in a simpler form by first dividing numerator and denominator by c, when it becomes:

$$u_1 = \frac{\frac{fd}{c} \times u}{\frac{fd}{c} + u - f}$$

As we have already seen from formula (4), $\frac{fd}{c}$ is the formula for the hyperfocal distance. Using the symbol H for it, the formula for the nearest distance to which depth extends, when focussing on an object at a distance u, becomes:

$$u_1 = \frac{Hu}{H + u - f} \qquad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

In words, *the nearest distance rendered without perceptible unsharpness when focussing sharply on an object at a distance* u *is equal to the hyperfocal distance (for the particular focal length and lens aperture) multiplied by the distance* u *and divided by the sum of the hyperfocal distance and the distance* u *less one focal length.* All quantities expressed in the same unit, ft., inches or centimetres.

For example, when focussing on an object 10 ft. distant with a 6-in. lens at $f/16$, what is the nearest distance in "focus," if 1-100th of an inch be taken as the standard of permissible unsharpness? Here the hyperfocal distance, given by formula (4b), is:

$$\frac{100 \times 6 \times 6}{16} = \frac{3,600}{16} = 225 \text{ ins.}$$

The required distance is therefore $\frac{225 \times 10 \times 12}{225 + 120 - 6} = 80$ ins. $= 6$ ft. 8 in.

Formula (8) can be further simplified by omitting the f in the denominator. If the value of the hyperfocal distance or the distance u of the object is great relatively to the focal length of lens, the effect of this latter is negligible in formula (8), which then becomes:

$$u_1 = \frac{H \times u}{H + u} \qquad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8a)$$

Practically the more exact formula (8) is necessary only when the object is very near to the lens, e.g., a few multiples of the focal length

away from it, and when also the hyperfocal distance is small in consequence of the shortness of the focal length of the lens or use of a small stop.

Far Distance.

The formula for the farthest distance rendered without permissible unsharpness when focussing sharply on an object at a distance u is derived in like manner from the construction of fig. 7.

In the similar triangles $B\,F\,D$ and $G\,F\,G$,

$$\frac{L\,F}{F\,P} = \frac{d}{c}$$

But $F\,P = L\,P - L\,F = v - v_2$

$$\text{Therefore } \frac{v_2}{v - v_2} = \frac{d}{c}$$

$$\text{or } v_2 = \frac{dv}{d + c} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (b)$$

Substituting as before the values of v and v_2 in terms of f and the respective object distances u and u_2 into equation (b), we get:

$$\frac{f\,u_2}{u_2 - f} = \frac{fdu}{(u - f)\,(d + c)}$$

$$\text{Whence } u_2 = \frac{fdu}{fd - c\,(u - f)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

Again we divide numerator and denominator by c and obtain:

$$u_2 = \frac{\frac{fd}{c} \times u}{\frac{fd}{c} - u + f}$$

Replacing $\frac{fd}{c}$ (hyperfocal distance) by the aymbol H, the formula becomes:

$$u_2 = \frac{H \times u}{H - u + f} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10)$$

In words, *the farthest distance rendered without perceptible unsharpness when focussing sharply on an object at distance* u *is equal to the hyperfocal distance (for the particular focal length and lens aperture) multiplied by the distance* u *and divided by the difference between the hyperfocal distance and the distance* u *plus one focal length.*

For example, in the circumstances chosen for the illustration of formula (8) for near distance, the far distance to which depth extends when focussing on 10 ft. is:

$$\frac{225 \times 10 \times 12}{225 - 120 + 6} = 243 \text{ in.} = \text{say } 20 \text{ ft.}$$

As in the case of formula (8), formula (10) is further simplified by neglecting the odd focal length in the denominator and then becomes:

$$u_2 = \frac{H \times u}{H - u} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10a)$$

Formulæ ($8a$) and ($10a$) are quite accurate enough for almost all conditions which occur in practice, and are the formulæ to be used except when photographing on a scale which approximates to same-size reproduction.

Near and Far Depth Distances in Terms of Variable Disc of Confusion.

If, in accordance with the idea that the disc of confusion should be a certain small fraction of the distance at which the photograph is viewed, we adopt, say, 1-2,000th (= .0005) of the viewing distance as the value of c, the foregoing formulæ become much simpler.

If the distance of the object in sharp focus is u, the camera extension (i.e., viewing distance) is:

$$\frac{fu}{u - f}$$

Adopting 1-2,000th of this distance in place of c in formula (7), the near distance u_1 to which depth extends is:

$$u_1 = \frac{fdu}{fd + \frac{1}{2{,}000}\,\frac{fu}{u - f}\,(u - f)} = \frac{fdu}{fd + \frac{fu}{2{,}000}} = \frac{2{,}000\,du}{2{,}000\,d + u} \quad (11)$$

In words, *when focussing on an object at a distance* u *with diaphragm of diameter* d, *and adopting an angle of sharpness of vision of* 1-2,000th, *the distance of nearest object in "focus" is* 2,000 *times the diameter of the diaphragm multiplied by the distance of the object divided by* 2,000 *times the diameter of the diaphragm plus the distance of the object*

Remembering that from the standpoint of variable diameter of the disc of confusion, the hyperfocal distance is 2,000 d, it will be seen that the above corresponds with formula (8a), viz., near depth distance is:

$$\frac{H \times u}{H + u}$$

While formula (11) shows that on the basis of sharpness of vision, depth is independent of the focal length of the lens, this formula may be written in terms of the relative working aperture ($F.\,N°$) by substituting $\frac{f}{F.\,N°}$ for d.

Formula (11) then becomes:

$$u_1 = \frac{fu}{f + .0005u \times F.\,N°.} \quad . \quad . \quad . \quad . \quad . \quad (12)$$

In a similar manner the far distance u_2 to which depth extends (adopting a disc of confusion of 1-2,000th of the viewing distance) may be written as:

$$u_2 = \frac{2{,}000\,du}{2{,}000\,d - u} \quad (13) \qquad \text{or } u_2 = \frac{fu}{f - .0005u \times F.\,N°} \quad (14)$$

Here again, putting H for 2,000 d in formula (13) it is seen to correspond with formula ($10a$), viz., far depth distance is:

$$\frac{H \times u}{H - u}$$

When used in connection with the variable disc of confusion the two approximate formulæ ($8a$) and ($10a$) therefore becomes precise.

In the next article we will see how to find u, the distance on which to focus in order to obtain an equal degree of admissible unsharpness at the nearer distance u_1 and the farther distance u_2. G. E. B.

(To be continued.)

MAKING INCREASED CAMERA SALES IN THE AUTUMN.

THERE is a great burst of activity in selling cameras and accessories in the spring and summer, but during the autumn and winter it seems to dwindle down to almost nothing. This is a mistake, because in the autumn there are such events as shooting, tramping, football, and Christmas, all of which are excellent sales opportunities if sufficiently exploited.

Some of the camera displays from America arranged last autumn may suggest ideas for your own efforts along these lines.

John W. Hilton, Richmond, Va., U.S.A., appealed to the autumn hunter with an appropriate camera display. Autumn leaves, mainly oak, chestnut and sycamore, covered the window floor, with several saplings planted here and there. Along the rear the effect of a fence was obtained by planting saplings in close formation. Such articles as guns, golf sticks, game bags, and Kodaks were hung on the branches of the little trees. More cameras were scattered about the floor, backed up by the following sign:—

"Hunting With a Kodak."

Another Kodak display with the shooting appeal was made by the Owl Drug Co., Battle Creek, Mich. Sky-blue crêpe paper covered the background, which was banked with reeds, rushes, and autumn foliage. A rowboat was just emerging from the underbrush, with a large-sized camera placed in the prow of the boat. "Kodak as you go" was the message a card conveyed.

The Rouser Drug Co., Lansing, Mich., gave the Kodapod an autumn setting. Autumn leaves covered the floor, while cornstalks and sunflowers were banked around the sides and rear. There

was a low rail fence across the rear, a Kodapod being attached to the top rail. A near-by card suggested:—

"Use a Kodapod—Fastens Anywhere."

The Oseen Photo. Supply Co., Denver, Colo., employed dolls to excellent advantage in an autumn camera setting. A camera rested on a small tripod near the centre. Beside the camera was a large doll. She was posed in the act of manipulating the camera, her subject being a smaller doll, posing in front of a sheaf of wheat, with two large pumpkins placed on either side of it. At each far corner of the window was a similar sheaf of wheat, with pumpkins resting at the base of the same.

Kodak, Ltd., Regent Street, London, England, floored an autumn camera display with brown sateen cloth, over which different types of Kodaks were distributed. A large sign at the rear was captioned in the following convincing vein:—

"AUTUMN PHOTOGRAPHY—

"Kodak Photography can be practised at this as well as any other season of the year.

"Take a Kodak on your country walks and bring home photos. of the beautiful autumn effects, obtainable at no other season of the year."

The script of the card was in orange against a brown surface. Another card suggested:—

"KODAK PHOTOGRAPHY—

"You load in daylight.

"You develop in daylight.

"You print in daylight."

"It is daylight all the way" was an oval-shaped card of a grained brown, over which brown, green, and yellow ribbon streamers were hung.

B. M. Levoy, Inc., New York City, injected the Christmas atmosphere in their window display. They accomplished this by enveloping the background of their small show window with midnight-blue crêpe paper, against which was propped a scarecrow, stuffed with straw, and wearing an old coat and a pair of trousers. Grotesque features were painted on his head. Two cards, one held in each hand, bore the following message:—

"With the folks turning homeward for the gathering of the Clans
There's a golden chance to Kodak, says the Scarecrow Man."

"With the turkey on the platter and a Kodak in the hand,
There's a real Christmas for you, says the Scarecrow Man."

Turkey cut-outs were placed among the Kodaks exhibited on the floor. Framed photographs of pumpkin scenes reposed on the floor at the rear.

The Shaw Supply Co., Tacoma, Wash., put in a clever and effective window display with the idea of showing how the Christmas dinner party could be photographed. Usually the light is poor, so artificial light is resorted to, with the result that a flashlight photograph is possible. The display contained a real dining-room table, with places set for six. Instead of the usual table furnishings, photographic accessories were substituted. Beside each diner's place was a tripod, about as tall as the table, with a camera resting upon it. Large Kodak pictures, cut round-shape, performed the duty of plates. The cocktail was substituted by an Eastman flashlight powder, with rolls of film serving as water glasses. Eversharp pencils and fountain pens were used instead of the conventional cutlery. A huge platter occupied the pride of place at the table, with a large enveloping box replacing the turkey, surrounded by small boxes of film, developing powders, pencils, and a measuring glass, for the fixings. The entire display was backed up by a large sign at the rear, which proclaimed:—

"When the table is set and the guests are gathered about it, take a Flashlight Picture with your Kodak. We will give you expert information on how to take the picture."

The Christmas atmosphere in a camera display by Koenig's, Newark, N.J., was carried out by suspending a holly wreath halfway down the ceiling at each side. A card fitted inside each wreath read:—

"Brownie Cameras for Christmas."

Brownies were set on top of their cardboard boxes about the green crêpe window-floor, with a border of rose crêpe paper.

A well-expressed announcement, occupying no more than two inches, single column, in the rotagravure section of one of the Boston dailies, was that of the Robey-French Co., Boston, Mass. Here is the piece of copy in question:—

"A Snowy Scene,
A Kodak,
A well-developed film,
A perfect print,
Nature supplies the first,
The rest,
Robey-French Co.,
30, Bromfield Street."

Also use it as a window card; it is concise enough for this purpose.

E. A. Dench.

SILVERING MIRRORS.

The following note is reprinted from a recent issue of "Popular Astronomy," sent us by Mr. Edward S. King, who writes as follows:—The method described below is a modification of Lundin's process as developed in experiments made by my son, Everett, who died in 1917. These experiments were made by him during the summer of 1912. He found that the original formula contained an excess of formaldehyde, so that if the silver nitrate was doubled, a much thicker coat could be obtained. As he remarked, a thick coat of silver stands burnishing better and lasts longer. The chief point he discovered was in regard to the temperature. He found from his experiments, which were carefully recorded with all particulars, that the absolute temperature, within reasonable limits, did not make much difference; but if the mirror was about 10 deg. to 20 deg. Fahr. warmer than the silvering solution, a thicker coat resulted and the process was more reliable. Some have thought that the stannous chloride used in the Lundin process acts on the surface of the mirror. If it is washed off thoroughly enough to prevent chloride stains on the silver deposit, it seems that no other effect can be possible.

The burnishing of the mirror is of utmost importance. He found by experiment that the average reflectivity of four unburnished mirrors tested was photographically about 58 per cent., against an average of 78 per cent. when burnished. The mean of 13 tests gave a reflectivity of 83 per cent. after burnishing. The best coat obtained reflected 90 per cent. of the photographic light. The directions, which follow, were prepared by him and are now in use in Harvard observatory. For silvering a 24-inch mirror it requires about two litres of solution or 20 times the formula.

Directions for Silvering Mirrors.— First a saturated solution of stannous chloride is made up, and diluted for use with an equal volume of water. Several wads of clean absorbent cotton are laid out on a clean sheet of paper. The surface of the mirror is carefully rubbed with one of the wads dipped in nitric acid. This removes the old coat of silver, with all the dirt which may be adhering.

After thoroughly washing off the nitric acid, a fresh wad of cotton wet with the stannous chloride solution is rubbed over every part of the surface of the mirror. Water is then poured over the mirror, and the surface is rubbed, first with the same wad, and then with a fresh one. Great care should be taken to remove all traces of the stannous chloride, as, if any is left on, it makes the coat granular. One should be careful not to touch the surface with the fingers, as any trace of grease is fatal.

The mirror, if a small one, may then be placed in a tray just a little larger than itself, and covered with water, at temperature from 65 deg. to 70 deg. Fahr. If a large mirror, a band of waxed paper, tied tightly around the edge, makes a dam and serves the same purpose.

Two solutions are required as follows:—

A.	Water	100 cc.
	Silver nitrate	4.3 gm.
	Add strong ammonia just sufficient to dissolve the precipitate first formed.	
B.	Water	20 cc.
	Formaldehyde (Merck)	4 cc.

The temperature of these solutions should be about 45 deg. and 50 deg. F.

The wash water is then poured off the mirror, the solutions quickly mixed and poured over the mirror. Silver will begin to be formed on the surface of the glass almost at once, the solution turning to a red-brown colour. In about half a minute, the solution

begins to turn muddy, with a granular black precipitate. The mirror should be left in it until this precipitate begins to stick to its surface. This usually requires from three to five minutes. The mirror is then washed with wet cotton and flowing water, and set on edge to dry.

It is important to get as thick a coat as possible, for such a coat stands burnishing better and lasts longer. The thickness can be roughly estimated by observing the amount of light transmitted by it. An electric-light filament can barely be seen through a thick coat.

The burnishing is done with a pad of chamois skin, into which some very fine rouge is worked. The best rouge is that washed out from the cloths used after the final polishing in the making of a large lens. The rouge is only sufficient to colour the pad. The surface of the pad must be kept perfectly free from dust, or the delicate surface of the silver will be scratched.—(Signed) Everett T. King, Harvard College.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Latest date for entries, August 30. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Prince's Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1. Latest day for entries and exhibits, August 31.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Latest date for entries, August 25 (carrier); August 26 (hand). Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 21.—Rotherham Photographic Society. Latest date for entries October 4. Hon. Secretary, S. G. Liversidge, Orissa, Gerard Road, Rotherham.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 8 to 12:—

ENLARGING.—No. 21,587. Artificial light photographic enlarging apparatus. A. C. W. Addis.

COMPOSITE PHOTOGRAPHS.—No. 21,829. Production of composite photographs. T. Brooks.

CAMERA ATTACHMENT.—No. 21,674. Attachment for cameras. F. L. and T. Dodman.

PRINTING FRAMES.—No. 21,521. Photographic printing frames. W. G. Hubbard.

CINEMATOGRAPHY.—No. 21,522. Cinematographic apparatus. S. H. Crocker.

CINEMATOGRAPHY.—No. 21,535. Cinematograph camera traversing and tilting apparatus. E. G. Marklew.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

CORRECTION OF OBLIQUE AERIAL NEGATIVES.—No. 180,360. (December 18, 1920). The invention consists in a method of transforming oblique photographs in which the negative is progressively exposed and transmitted to a sensitive receiving surface through a narrow slit fixed at right angles to the optical axis of the lens.

As in photographing from aeroplanes, exposure is nearly always made when the plane is inclined to the ground, pictures are obtained which appear oblique as compared with photographs taken when the camera is in a plane parallel with the object photographed. Hence the negative obtained from a camera on an aeroplane is an oblique negative, and to explain the invention, in the description here following, the treatment of such a negative is referred to.

In figs. 1 to 7 of the drawings it will be seen that the plane of exposure, 1, of the photographic camera, stands perpendicularly towards the optical axis 2, and the latter has an inclination α° towards the ground, indicated at 3A (fig. 1). According to the invention the process of transformation must be adjusted corresponding to the condition at the moment of exposure. For example, if the negative plate 1 taken from the aeroplane, or a copy obtained from the same, is placed perpendicularly towards the optical axis 2, the picture must be projected on a sensitive surface indicated at 3, which is either (as shown in fig. 2) adjusted to an angle with the optical axis equal to the angle α° formed between the optical axis and the ground at the moment of exposure, or (as shown in fig. 3) is at right angles to the optical axis, in which case the lens must be moved to correct perspective and the surface 3 moved to keep it in focus with the lens.

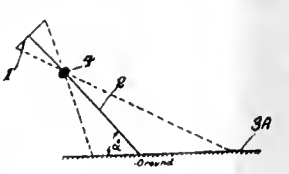

Fig. 1.

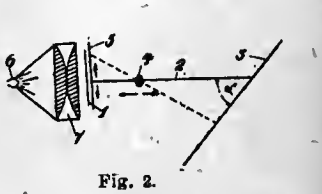

Fig. 2.

As the objective 4 only projects a sharp picture of a surface standing perpendicular towards the axis on to a receiving plate, also perpendicular towards the optical axis, there is only, at the shown position of object and picture, quite a narrow strip of the picture having a sharp reproduction, i.e., in the line of intersection between the sensitive surface and a plane perpendicular to the optical axis at the intersection of the latter with the sensitive surface.

To obtain, however, a sharp picture all over the surface of the receiving plate the negative is projected through a narrow slit, formed in a suitable member, indicated at 5, in the several drawings, moving over the negative, whilst the objective 4 and the receiving plane 3 are adjusted in such a way as to enable

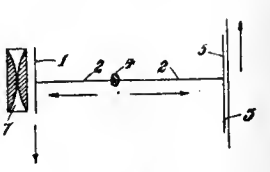

Fig. 3.

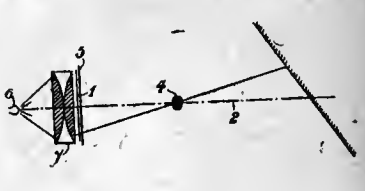

Fig. 5.

the latter to receive in a clear and defined manner the strip of the picture formed by the moving slit 5. The source of light 6 necessary to obtain the projection of the negative is disposed behind the plate, between which and the light is placed the usual condensing lens, as indicated at 7.

By adopting this stripwise formation the whole negative is gradually and correctly transformed and a sharp picture obtained. The objective is therefore moved correspondingly to the progressive projection for each moment of the whole process of transforming the oblique view into one as seen horizontally.

It is of great importance for the perfect transformation of the pictures that the negative, or picture, the slit, the objective, and the sensitive receiving plate have the correct proportion of motion one towards the other.

The slit bearer 5 may be placed before the sensitive surface 3 (fig. 3), or may be placed before the picture to be transformed (figs. 2, 4 and 5), or before the objective; it must, however, in any case remain permanently in a plane perpendicular to the optical axis 2 of the objective lens 4.

As the slit is preferably held in this position it is necessary that the picture to be transformed as well as the sensitive surface must receive a transverse motion one opposed to the other, perpendicularly to, and at the angle α^0, respectively to the optical axis, so that the whole picture to be transformed is projected through the slit. Alternatively, of course, the receiving surface might be held against transverse motion while the slit member is moved across the receiving surface.

The variations of scale for enlarging and the corresponding adjustment for sharpness of the picture require that the distances between the objective 4 and the sensitive surface 3 (fig. 3) on the one side of the objective 4 and the picture or

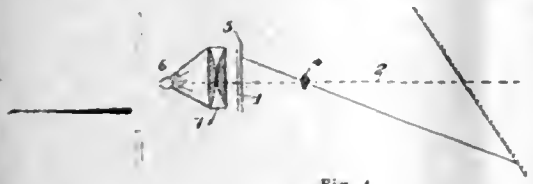

Fig. 4.

negative 1 on the other side are variable. For this purpose several arrangements are possible; either the negative plate 1 is stationary in the direction of the optical axis and the objective 4 and the receiving surface 3 are movable along it, or the objective 4 is stationary in the optical axis, while the receiving surface 3 and the plate 1, together with the associated condenser 7 and illuminant 6, are movable in the direction of the optical axis. Also the receiving frame 3 may be stationary in the direction of the optical axis and the objective 4 and plate 1, together with its associated condenser 7 and illuminant 6, may move in it. These motions in the direction of the optical axis must be continuous and progressive and must be positively connected with the above described transverse motions of receiving surface and picture.

In figs. 6 and 7 the negative 1 is illustrated as comprising a network with a diminishing appearance, that part of the negative nearest the subject photographed being indicated by the numerals 8 and 9, while the distance is indicated by the numerals 12 and 13. As shown in fig. 6, the negative 1 and the receiving surface 3 are parallel, and it is supposed that the near edge 8, 9 is being transferred to the receiving surface 3 through the slit 5. Through this slit 5 a thin area of the plate is transformed correspondingly, on a selected scale, within the optical limits prescribed by the lens used; the negative plate 1 is then moved in the direction of the arrow 10 (fig. 6) so that the next narrow parallel strip of the plate appears in the slit and is thrown on the receiving surface 3, which meanwhile is moved in the direction shown by the arrow 11, which movement is opposite to the movement of the negative plate 1 indicated by the arrow 10. This successive projected parallel strip would normally appear, however, on the receiving surface, on account of the diminishing appearance seen in the plate 1 (figs. 6 and 7) at a different enlargement to the preceding slip. To bring it

Fig. 6.

Fig. 7.

on the same scale as the latter the objective is moved in a direction along the optical axis 2 towards the plate 1, and the receiving frame 3 in the direction along the optical axis away from the plate 1. To adjust the second parallel strip two main motions have therefore been necessary:

(1) A motion of the plate 1 and of the receiving frame 3 in the respective directions indicated by arrows 10 and 11 transverse to the optical axis (transverse motion).

(2) A motion of the objective 4 in the direction of the optical axis 2 towards the condenser 7, and of the receiving frame 3 along the optical axis 2 away from the condenser 7 (axial motion).

For each following parallel strip of the plate new adjustments in the direction of these two movements would be necessary.

In figs. 8, 9, 10 and 11 a simple mechanical arrangement is diagrammatically shown for obtaining the required movements of the lens and receiving surface and negative.

In these figures the negative is indicated by the numeral 1, and the casing, indicated by the numeral 4a, contains the lens

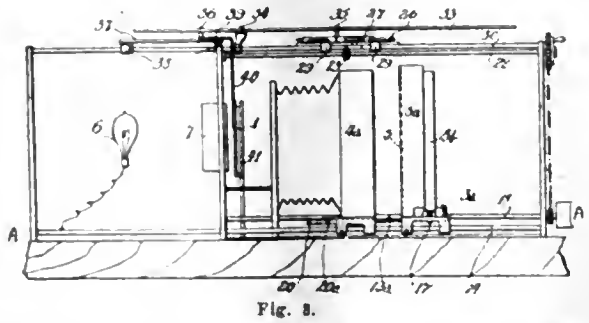

Fig. 8.

4, while the numeral 3a indicates a sliding carriage on which a casing 3b is mounted for transverse movement, the casing 3b containing the receiving surface 3, while in front of the casing 3b, and fixed to the carriage 3a, is a further compartment 5a for the slit bearer 5.

In the arrangement illustrated it is supposed that the lens box 4a and the sliding carriage 3a are slidable along runners or guides 14, which form part of a fixed framework of the apparatus.

The parts 1, 4a and 5a will be distanced apart according to the known laws for correct projection. In order to carry out the photographic process according to the invention the plate 1 and the receiving surface 3 will be moved at right angles to the optical axis and in opposite directions.

Referring particularly to figs. 8 and 10, the receiving surface 3 is carried across the carriage 3a by means of a pinion 15, a chain 16, and a pinion 17 fixed to the carriage, the pinion 15 being slidably mounted on a shaft 18, which is operated from a motor through a gear box indicated at 19. Any suitable arrangement may be used for connecting the receiving surface to the moving chain.

As the aeroplane plate is inclined when it is exposed, it will be necessary to continuously correct the position of the lens with regard to the receiving surface as the latter is moved over its carriage in order to correct the perspective. In order to obtain this adjustment of the lens during the process of transformation a bell crank pivoted at 19 (fig. 10) is fixed at a suitable position beneath the lens box; each arm of the lever is slotted, the longer arm 19a passing under the carriage 3a so that a finger (not shown), depending from the casing 3b, engages in its slot. Then as the surface 3 is moved across the apparatus the bell crank is tilted about its pivot. The shorter arm 19b is utilised to move the lens according to the known

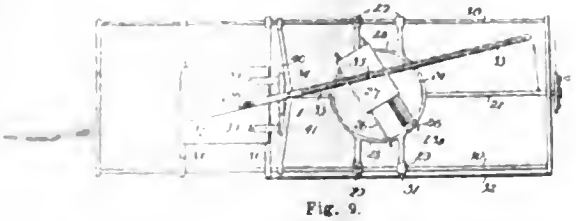

Fig. 9.

laws of perspective. To this end the lens box 4a is provided with a rod 20 having a depending finger 21 fitting into the slot of the arm 19b, so that the angular movement of the latter arm is converted into an axial movement of the lens, the arm 19b being preferably associated with a scale 19c, and the rod 20 mounted on a threaded member 20a so that the position of the rod 20 along the arm 19b can be varied according to the angle α^0 of inclination of the negative to its subject during exposure, that is, the smaller the angle α^0 the nearer will the rod 20 be to the arm 19a of the bell crank.

As the lens has been moved with regard to the receiving surface it becomes necessary to enforce a movement of the latter

proportionally to the movement of the lens in order to keep the receiving surface in focus with the lens. To this end a bell crank (figs. 10 and 11) is pivoted at a point 42 to the lens casing; the two arms 43 and 44 of the bell crank being slotted for the reception of bowls or pins 45, 47, fixed to arms 46, 48, carried by the negative holder 41 and receiving surface carriage 3a respectively. The distance of the pivotal point 42 from the lens is equivalent to the geometrical mean proportional of the distances separating the pins 45 and 47 from the lens, when they are in correct focal position therewith; with such a construction the receiving surface is compulsorily moved along the optical axis to keep it in focus as the lens is compulsorily moved along its axis, as described above.

In fig. 11 the distance of the pivotal axis 42 from the lens is indicated by the reference letter x, and it will be seen that

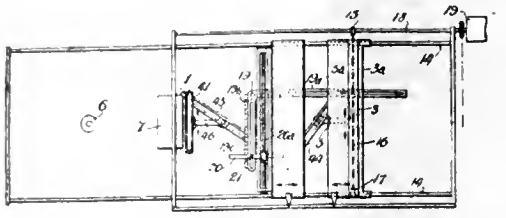

Fig. 10.

the arms 46, 48 are given the same length, and, further, that the angle between the arms 43 and 44 of the bell crank is a right angle.

During the movement of the surface 3 it is required to move the aeroplane negative 1 in proper relation for correct transformation of its subject. The construction enabling this to be carried out is best understood by reference to fig. 9, the arrangement shown in fig. 9 being superimposed at a suitable height above the arrangement shown in fig. 10 to allow the interposition of the camera and casings 5a and 3b as shown in fig. 8. The shaft 22 (figs. 8 and 9) is coupled to the shaft 18 (figs. 8 and 10) preferably by means of a chain drive indicated by dotted lines, so that a simultaneous rotation is obtained, this shaft 22 being connected through bevel gearing indicated conventionally at 23 to a rack 23a secured to a member 27 slidable on guides 26 on a turntable 24. The element of the bevel gearing fixed to the shaft 22 is mounted thereon so that the bevel can be slidden along the shaft, while rotation with the shaft is assured. The reason for this construction is that the turntable 24 is mounted in a frame 28 carrying bearings 29, which permit the table to be supported on the longitudinals 30 of the framework.

According to the angle of inclination $\alpha°$ the table is moved along the guides until a pointer 31 on one of the bearings 29 registers with a graduation on a rod 32 equivalent to the angle of inclination, and the turntable 24, which is graduated, is also appropriately set in accordance with the value of the angle $\alpha°$.

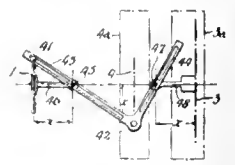

Fig. 11.

The rod 32 and the pointer 31 are not included in fig. 8 for sake of clearness. The framework also carries a proportional lever 33, pivoted at 34 and slotted in its longer arm to overlie the pin 35 on the slide 27. The short arm of the lever engages over a pin 36 on a platform 37 slidable transversely atong guides 38 carried on the framework. On the sliding member 37 are brackets 39 carrying depending members 40, which are connected to a suitable cradle 41 adapted to receive the negative 1, which is therefore in fixed relation to the illuminant as regards its position along the optical axis, the position of the illuminant being indicated at 6 in figs. 8 and 10.

With these two constructions the progressive movement of the negative 1 is assured, and the movement is regulated by the movement of the receiving surface 3. As the receiving surface 3 is traversed across the apparatus from the mechanism operated by the shaft 18, the shaft 22 is rotated and, operating the rack 23 on the turntable, causes the sliding member to move along the guides 26, and the pin 35 on the alide pushes the proportional lever so as to tilt it about its pivot 34, resulting, through the connection 36 with the platform 37, in a proportional movement of the cradle 41 carrying the negative 1. —Carl Janzer, Junr., 37, Hohenheimer Strasse, Stuttgart.

The following complete specifications are open to public inspection before acceptance:—

Apparatus.—No. 184,189. Method of and apparatus for obtaining photographs from moving objects, such as aeroplanes, airships, ships, motor-cars, trains, and any other vehicles. H. L. Cooke.

News and Notes.

The Rotherham Photographic Society's Annual Exhibition will be held in the Drill Hall from October 18 to 21 next. Particulars may be had from the exhibition secretary, S. G. Liversidge, Orissa, Gerard Road, Rotherham.

Exhibition at Turin.—An exhibition of photographic and optical goods, including cinematograph apparatus and appliances, is to be held at Turin during the month of April, 1923. The Turin Chamber of Commerce state that the exhibition will be of an international character.

Death of Mr. H. W. Blunt.—We regret to have to record the death of Mr. H. W. Blunt, of Southport, who died on the 15th inst. after an illness of nearly two years' duration. He was a partner in the photographic firm of Starfield and Co., of Renshaw Street, Liverpool, and a director of Leslie Bros., Ltd.

Camera Smuggling.—At Dover, last Saturday, a man and his wife coming to London from the Continent were each fined £44 14s. for smuggling four cameras and two pairs of binoculars. The Customs official, prosecuting, stated that only a severe penalty would stamp out camera smuggling, which was getting rife, as cameras could be bought for next to nothing on the Continent.

Press Photographs are often "turned down," says the "Newspaper World," because of an insufficiency of details supplied by the contributor. Particulars of the occasion such as the date and names, etc., in full, cannot be given too carefully. It is not neces-

sary to write out a smart caption, as this is almost always done by the editorial staff, although, of course, a really bright idea is welcomed.

EXHIBITION SENDING-IN DAYS.—Readers who intend sending in pictures to the two London exhibitions are reminded that Wednesday next (30th inst.) is the last day for receiving entries for the London Salon of Photography (5a, Pall Mall East, London, S.W.1), and that to-morrow (26th inst.) is the last day for receiving pictures for the Royal Photographic Society's exhibition (35, Russell Square, London, W.C.1).

PHOTOGRAPHER FINED FOR OBSTRUCTION.—It is stated by the local Press that visitors to Cheddar Gorge are importuned by a small army of photographers to have their portraits taken. But, according to the police, their persistence has developed into a nuisance, and last Saturday one of them was summoned at Axbridge for causing an obstruction, and was fined 5s. He said he was one of six ex-soldiers who were trying to earn a living by photography in the district.

BROCKEN "SPECTRE" PHOTOGRAPHED.—A Reuter wire from Paris states that the photographers belonging to the party that has accompanied Professor Legarme, the French scientist, to the summit of Mont Blanc have succeeded in photographing the so-called "Brocken spectre" for the first time. The Brocken spectre, it may be stated, is an optical phenomenon caused by the sun's projection of the shadows of the summit and the objects on it in gigantic proportions on a wall of mist.

THE ALL BRITISH £3,000 COMPETITION.—A very interesting 16-page booklet describing this competition has been issued, and copies of it may be had from dealers or from the secretary, All British Competition, 4, Oxford Street, London, W.1. In addition to reproductions of some of the prize pictures, the booklet contains much useful information on starting photography, and a capital reproduction of a photograph showing the judges at work on the first section of the competition.

PHOTOGRAPHING CHARRED DOCUMENTS.—The American scientific papers tell how records charred beyond recognition in a fire at Augusta, Ga., have been made legible by the Bureau of Standards. Renovation by chemical means having failed, Raymond Davis, chief of the photographic laboratory, laid the charred sheet between two photographic plates with the emulsion side next the paper. After two weeks of contact the developed plates gave a plainly readable record. Where there was contact between the charred paper and the plate the latter was affected, but where the ink had been the chemicals of the plate were unchanged.

CHARGES FOR ELECTRICITY SUPPLY TO PHOTOGRAPHERS.—The question has arisen in various Northern centres as to the terms for electricity which local authorities should concede to photographers. In Blackburn (says "Electricity") a scheme has been introduced whereby power rates are charged certain hours when the studio is likely to be in use, the period being extended in the winter when the light is not so prolonged. In other quarters, power rates are charged for all photographic work, the Committees holding the opinion that this comes within industrial occupation. The whole subject is likely to be brought forward in the near future with a view to securing some degree of uniformity in the country.

A FRENCH PIONEER OF PHOTOGRAPHY.—The claims of an almost forgotten pioneer of photography, Hippolyte Bayard, are being urged by the Parisian press. Bayard, a native of Breteuil, says one French authority, is said to have invented the first process for photography on paper, which he communicated to the Academy of Sciences in 1839, while Niepce and Daguerre were still experimenting without success. He had then produced the first positive picture on paper, and soon afterwards was the first to develop the latent images on paper. For nearly fifty years afterwards he continued photographic research, but his name was quite forgotten soon after his death. "France," says the *Matin*, "must take better care of her glories." As briefly stated on page 509 of the current "B. J. Almanac," Bayard had on June 4, 1839, an exhibition of positive prints made directly in the camera.

MICROGRAPHIC PHOTOGRAPHY IN TEXTILE TRADE.—Reuter's New York representative states that a local scientist of Boston, U.S.A., has opened a studio for the purpose of specialising in micrographic photography. The business consists of making photographs of textiles, jewels, and other extremely small objects or details of objects for purposes of identification or reproduction. For example, if a merchant wants a sample of cloth reproduced, he has micrographic photographs made of the goods showing details of the fibre in the threads, the tightness or the looseness of the twist, and details of design. Such photographs, it is said, are of much assistance to the textile maker in reproducing goods, and to the purchaser in determining whether the reproduction is truthful. The micrographic pictures also easily identify various kinds of threads, whether they be silk, wool, or cotton.

P.P.A. CONGRESS: ASSISTANTS' EVENING.—As announced in the first issue of the "Record," the President and Council of the P.P.A. invite all photographic assistants as their guests at the Prince's Galleries, Piccadilly, on Thursday, September 14, from 6 p.m. to 10 p.m. This evening has been set aside entirely for them, and it is hoped that all who possibly can will be present. There will be a talk by Mr. Marcus Adams on the exhibition of pictures, and Mr. George Hana will give a short address on "Assistants as Associate Members," after which a short discussion will be opened. During the evening the result of the "Window and Show-Case Dressing Competition" will be announced and the awards distributed. Refreshments will be provided and musical items rendered. It is the earnest desire of the President and Council to make this evening a great rally for assistants where they can feel at home, and preparations are being actively proceeded with to receive a record number of visitors. No charge of any kind will be made, the Council inviting the assistants to come as guests of the P.P.A. Invitation cards are now available and will be supplied to employers who make application to Mr. Gordon Chase, Bromley, Kent. Early application should be made, and in no case later than August 31. Members of the P.P.A. may invite all their assistants, but non-members are restricted to two invitations.

AN ANALYSING ATTACHMENT for cameras is described in the "Optician" by C. F. Smith, who writes: In view of Professor Cheshire's recent advocacy of the Nicol prism for viewing pictures in galleries, a description of an analysing attachment for cameras may be of some interest. In the early part of last year the author noticed accidentally that transparent objects, or objects possessing a transparent surface layer, had the property of polarising reflected light, the degree of polarisation being dependent on the angle of incidence. This fact suggested a solution of the reflection problem, one which has always troubled professional photographers when photographing glassware, furniture, or interiors. All that was necessary was to attach a suitable analyser to the camera, and adjust until the most annoying reflexions were wholly or partially suppressed. A few experiments showed that a plate of tourmaline was the best form. The angle of field of a Nicol prism was too small; a pile of glass plates arranged obliquely to the axis spoilt definition, while a black glass reflector meant twisting the camera into very awkward positions. The tourmaline is about one millimetre in thickness, and can be attached in the same way as a filter, i.e., normal to the axis. The colour, which is usually a pale yellow or green, has the objection of increasing exposure by about four times, but otherwise the performance is satisfactory. Two interesting photographs of some household objects accompany the article, the exposures being made with the tourmaline in its positions of minimum and maximum effect.

PACKING NEGATIVES.

To the Editors.

Gentlemen,—May I be permitted to supplement your useful "Ex Cathedra" remarks on "Packing Negatives" by pointing out that although negatives packed in card plate-boxes, and surrounded by corrugated paper, may come safely through the post in nine cases out of ten, as you mention, yet the fact should never be overlooked that if the parcel has heavy pressure applied (as is often the case when at the bottom of a pile of parcels) no amount of corrugated will prevent such pressure being transmitted to the glass?

Speaking from long experience, one of the most frequent cause of breakage is allowing lateral shift of the negatives in the plate-box. If not in envelopes they should be wedged all round with tissue paper. It is also inadvisable to include more than one size of plate in a plate box. If this must be done, a stout card the same size as the larger negatives should be placed on top of them; the smaller wrapped tightly in a parcel (secured with gummed strips or string) and then stuck to the card with gummed paper, the space around being filled with soft packing.—Yours faithfully,

E. A. S.

THE "FREE SITTING" AGAIN.

To the Editors.

Gentlemen,—With reference to the letter of Mr. H. M. Robinson on this subject, in the "B.J." of August 11, may I point out that while many photographers will agree with him that there are occasional cases in which a "free sitting" is a legitimate business proposition, yet his contention that "no harm is done to brother photographers" by those professionals who make a regular thing of the "free sitting" stunt, is negatived by the fact that these indiscriminate invitations do certainly induce an idea, in the mind of people receiving them, that photographic work must be very easily and cheaply produced if it can be given away so freely, and that, consequently, the photographer who asks a good price is a profiteer of the worst kind. I have had this point of view put before me more than once by members of "*the* profession" who have assured me that they could get as many photographs as they wanted taken for nothing!

Then, again, there are other people who look upon these "free sitting" offers as an attempt of the photographer to foist his wares upon them or to make a profit out of them, and who consequently, when they want photographs, prefer to pay for them, and not run the risk of the photographer making some use of their portraits to which they might object, it appearing to be pretty well known by this time that by giving the "free sitting" he acquires the copyright of the pictures taken.

In the course of my own practice I have recently had more than one sitter, of some public importance, come to me in preference to accepting "free sitting" invitations, and the "stunt" thus appears to defeat, at times, its own purpose. Probably almost the only cases in which it pays to give "free sittings" are those of local clergy, for whose portraits, sold, of course, by their permission, there is very often a good local demand; and there are occasionally other local celebrities whose pictures may make a good showcase draw, but beyond this I do not think it is wise for the average photographer to go.—I am,

Yours faithfully,

DRINKWATER BUTT, F.R.P.S.

THE QUANTUM THEORY OF PHOTOGRAPHIC EXPOSURE: A CRITICISM.

To the Editors.

Gentlemen,—The criticism ("B.J.," July 28, p. 443) by Mr. F. C. Toy of the experiments of Messrs. Trivelli and Righter, and the quantum theory of exposure of Dr. L. Silberstein is, of course, quite in order, and its main contentions will be answered by these authors in due course. There is a possible implication, however, in Mr. Toy's argument upon which the writer would like to comment. Mr. Toy, referring to a statement of Silberstein, says "The first and most natural assumption of all is that the grains themselves are different; from the chemical point of view there is no reason why this should not be the case." The possible implication is that this alternative point of view was not considered in this laboratory. On the contrary, in a paper on "The Size Frequency Distribution of Particles of Silver Halide in Photographic Emulsions and its Relation to Sensitometric Characteristics," by the writer, in conjunction with E. P. Wightman and A. P. H. Trevelli, an alternative view of chemical differences between the grains, as due to localised sensitiser, is fully discussed and compared with the quantum theory of exposure. This paper was sent to the "Photographic Journal" in abridged form (abridged because the "Journal" does not publish lengthy papers) on March 27, and acknowledged April 19, but was rejected by the Journal Advisory Committee. The full paper is to appear in the "Journal of Physical Chemistry," while the abridgment is included in the first of a series of papers on "Studies in Photographic Sensitivity," to appear shortly in the "Journal of the Franklin Institute."

This letter has been written, not to deal with Mr. Toy's criticisms of the quantum theory, but to explain why the alternative view of grain sensitivity, which he regards as most natural (as it is to a chemist, though not perhaps to a mathematical physicist) did not appear to have been canvassed in this laboratory. It has been, but the circumstances referred to have delayed the public statement. As to the main question at issue, it has appeared to the writer for some time that the best chance of an *experimentum crucis* lies in the application of desensitisers as follows:—

1. It must be possible to remove completely the desensitiser prior to exposure. Otherwise the desensitising effect may occur by destruction of nascent latent image.

2. If this condition is secured, previous treatment with a desensitiser (chromic acid is being tested *inter alia*) should destroy the localised sensitiveness, if such a chemical difference is the cause of differential grain sensitivity.

3. If the original quantum hypothesis of Silberstein is correct, desensitising of the type described would not be possible, and the same differential grain sensitivity would exist before and after treatment.

Micro-chemical experiments with one-grain layers on these lines are being carried out by the writer and his collaborators, and the results will be communicated as soon as available.—Yours faithfully,

S. E. SHEPPARD.

SCRATCHED V.P. NEGATIVES.

To the Editors.

Gentlemen.—With reference to your remarks in "Ex Cathedra" of August 18 regarding scratched V.P. negatives. If enlargements are made with the mercury vapour lights, scratches on the back of either film or glass negatives do not show, and any retouching on the film side is much less apparent than when enlargements are made through a condenser.

We fully endorse your remarks *re* the packing of negatives for post or parcels delivery in every respect, and would add that a wooden case with open ends is not entirely safe. The box should be strongly made, with a lid either nailed or screwed on. We are at all times pleased to send suitable boxes free of charge to any photographers requiring prints or enlargements from us.—Yours faithfully.

Managing Director.

THE RENOVATION OF DAGUERREOTYPES.

To the Editors.

Gentlemen,—An article in the "British Journal" of August 4, p. 458, appears to me to be so likely to bring disaster on the photographer who may place reliance on it that a warning is desirable in his own interest, as well as that of the owner of the treasured and irreplaceable record.

I have been informed of a case in which a Daguerreotype was entrusted to a photographer of the highest standing with a commission for copies and paintings amounting to about £150, but the Daguerreotype was spoiled by an assistant, whether by rubbing, by the long stay in cyanide necessary to remove deep-seated tarnish, or by other means, I do not know. Not only did the photographer lose the order, and probably the connection, but the patron had to be faced with the information that his priceless treasure was destroyed.

The first statement calling for criticism is that "a Daguerreotype image cannot be rubbed off by ordinary means." This may lead the photographer to suppose that he may safely try what has been the ruin of so many Daguerreotypes, an endeavour to remove tarnish by rubbing with a cloth.

What is the object of the preliminary immersion in spirit? Is the writer confusing glass positives with Daguerreotypes? Positives were sometimes varnished with a solution of gums in alcohol,

sometimes with a material not soluble in spirit, and commonly not varnished at all. Of the very many Daguerreotypes that have passed through my hands, I have never seen one that was varnished, or that from any reason required a bath of alcohol.

The next proposition to challenge is that the cyanide and hydrochloric methods are equally effective. Later on, however, the writer states that "cyanide, if given time, will act upon the picture itself." This is only what might be expected from the well-known action of cyanide on gold and silver. Cyanide is in extensive use for extracting gold from the ore, and in the extremely finely divided state in which gold is deposited in toning Daguerreotypes, its removal by cyanide is probably almost instantaneous. The added beauty and vigour resulting from gold-toning were so well recognised that probably few, if any, Daguerreotypes were made without it during the greater part of the period of their professional production. The loss of this beauty may not be noticed by the user of cyanide, as he has not the picture in its original state to compare with it after the loss. With the hydrochloric method I have removed tarnish so deep-seated that it is doubtful if any useful image would be left if the cyanide treatment had been continued long enough to remove the tarnish, and in the end the image was not only intact, but the beautiful rosiness of a well-toned Daguerreotype was in full evidence.

The last point to notice is the statement that the Daguerreotype is to be removed directly from the tap to the drying flame. There may in some places be a supply of tap water so soft that this may be done, but generally there is so much lime in the water that lines or patches of deposit will be formed, unless, as was regularly done by Daguerreotypists, a rinse in distilled water is given before drying.—Yours faithfully,

W. E. Debenham.

"OPERATOR" OR "POSEUR."

To the Editors.

Gentlemen,—We all detest the word "operator," but "poseur" will not do in place of it. The word "poseur" now refers to one affecting a "pose," and has this significance—that it already is used to denote a person who puts on airs—a "swanker." There would be constant confusion in the studio with this term, for the poseur is really the posee. What is wanted is something exactly to take the place of the hated word, and which will indicate that branch of photography now known as operating. How would "camerist" do? Surely no one could object to be called a camera artist!

I must thank your correspondent for the flattering things he says about my articles, all the more as I learnt a good deal of my business in his city. I had a studio in Liverpool nearly thirty years ago.—Yours faithfully,

J. Eyre.

TONING WITH TIN SALTS.

To the Editors.

Gentlemen,—The solution of potassium ferricyanide and ammonium bromide, recommended as the bleacher for sulphide toning in the "B.J. Almanac" for 1922 (p. 483), converts a silver image almost quantitatively into one of silver bromide. This has but little bearing, however, on the explanation of the chemistry of the Neugschwender process of toning with stannous salts, indicated by J. G. F. Druce in the July 21 number of the "B.J.," inasmuch as the reduction of silver bromide by sodium stannite solution may be expected to follow a similar course to the reduction of silver ferrocyanide—the salt stated by Druce, through some misapprehension, to be the product of the action of the ferricyanide-bromide bleach solution on the silver of any image.

The equation in col. 1 of p. 433, in the above-mentioned article, should read:—

$$2NaHSnO_2 = Na_2SnO_3 + Sn + H_2O.$$

It is worthy of mention that this decomposition was described by Ditte in the course of a lengthy and fairly exhaustive paper on the action of acids and alkalies on stannous oxide, in the "Annales de Chimie et de Physique," ser. 5, vol. 27, in 1882. And analyses were given for the product of the reaction between potassium ferricyanide solution and silver metal, both when in the form of a photographic image and as a powder in glass vessels, by Lumière and Seyewetz, in a paper on the composition of the silver image toned with various metals, in the "B.J.," vol. 52, in 1905.—Very truly yours,

E. R. Bullock.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

B. W. S.—You cannot do better than make a carbon transparency, which would reproduce the scale of tones in the original negative more correctly. Use a slow film for the negative.

C. A.—Any colour sensitive plate gives very little correction if used without a colour filter. There is an improvement with "Anti-Screen" or "Self-Screened" plates, but nothing like what you would obtain with even a K2 filter. We should advise you to get for your special work a K2, or even a K1, screen, and use the panchromatic film.

G. E. C.—"Ferric and Heliographic Processes," by George E. Brown, is now out of print, but you could possibly obtain a second-hand copy from Messrs. Foyle, 121-123, Charing Cross Road. We assume that you wish to render the indian ink more opaque for copying by ferro-prussiate. If so, we do not think you can do better than to add a red or yellow pigment. The aerograph colours sold by Winsor & Newton, 37-40, Rathbone Place, Oxford Street, W.1., should answer very well for this.

D. O. P.—The soda sulphite should be in clear crystals. It should be kept well corked, otherwise the crystals become dull and powdery. Such sulphite must be rinsed for a few seconds, in a measure, with enough cold water to cover it, the water poured away and the crystals dried on a clean cloth and weighed out. Warm water, not hot or cold, is the best to use. The ordinary form of sulphite (to be used in all formulæ, unless otherwise directed) is the "cryst." The "anhydrous" is a stronger variety, 1 part of which is equivalent to about 2 parts of "cryst."

R. H. J.—The trouble with the mounts is an old one, and with the cheap quality pulp board you use we are afraid that you will not be able to get over it. Cardboard makers manage to obtain flat boards by keeping them under pressure while drying, but this would be difficult with a gelatine emulsion surface. You might try hardening the prints in formalin, and then when surface dry, before they begin to curl, putting them under pressure, say, a large board with a couple of 56-lb. weights. Another plan, which has answered with smaller prints, is to put them while damp in a set of grooves rather narrower than the card, so as to put a strain on in the reverse direction while drying. When taken out dry they should be practically flat.

F. G. A.—A formula for dextrine mountant is:—

Best white dextrine	1 lb.
Cold water	to make stiff paste.
Water	10 ozs.
Oil of wintergreen	1 dr.

Mix the dextrine and water together in small doses of each, so as to ensure a mixture free from lumps and clots. Dilute with the further quantity of water, add the oil, and just bring the whole mixture to the boil, when it should be like clear gum. Pour into pots, cover up, and in from 12 to 24 hours it will be set to a hard and white paste of great adhesive power. The dextrine must be the best white; inferior dextrine remains treacly on cooling.

H. H. N.—In the case of negatives on celluloid cut or roll-film the following is a suitable method for stripping:—

Caustic soda	10 grs.	23 gms.
Formaline	10 minims.	20 c.c.s.
Water	1 oz.	1,000 c.c.s.

The celluloid negative is immersed in this solution until the film shows signs of detachment and can be rolled back with the finger. It is then placed in

Hydrochloric acid	25 minims.	50 c.c.s.
Glycerine	25 minims.	50 c.c.s.
Water	1 oz.	1,000 c.c.s.

in which it is removed from its original support to a glass or other base.

H. F.—The following one-solution metol developer would suit your purpose:—

Metol	150 grs.	17 gms.
Sodium sulphite	2½ ozs.	125 gms.
Sodium carbonate	3½ ozs.	175 gms.
Potass. bromide	16 grs.	1.8 gms.
Water	20 ozs..	1,000 c.c.s.

In making up all metol developers, dissolve the metol first, then the sulphite, and then the other chemicals, using warm but not hot water. For portraits, take stock solution, 1 oz.; water, 1oz. For landscapes, stock solution, 1 oz.; water, 2 ozs. Metol gives delicate negatives with great detail and little density unless development is greatly prolonged.

G. W. F.—You do not specify the size of negatives which you intend to take, so that it is difficult to indicate a suitable focal length. For cabinet heads nothing shorter than 14 inches is desirable, and for whole-plates at least 16 inches is needed. This ignores cartes and other small sizes for which a second lens is almost an essential. The standard outfit used to be a 10½-inch or 11-inch portrait lens working at *f*/4, and a 17-inch or 19-inch *f*/6 for large heads and general work up to 12 by 10. Dallmeyer's 3B and 4D or 5D are typical examples. If the extra cost is not an objection, anastigmats of these focal lengths and apertures would, of course, be better, especially if they have the soft focus adjustment. Your scheme for half-watt lighting is quite good, but if you had the lamps to raise and lower you could do with smaller candle power.

V. A. D.—(1) The ferro-prussiate print marked A is particularly good. (2) The Pellet process is for copies of line drawings only. From an ordinary tracing it gives a copy in blue lines on a white ground. The formula is:—

A.—Pure gum arabic	4 ozs.	200 gms.
Water	20 ozs.	1,000 c.c.s.
B.—Ferric ammonium citrate ...	10 ozs.	500 gms.
Water	20 ozs.	1,000 c.c.s.
C.—Ferric chloride (crystallised) ...	10 ozs.	500 gms.
Water	20 ozs.	1,000 c.c.s.

Add 8 vols. of B, then 5 vols. of C to 20 vols. of A, in small doses with constant stirring. The prints are developed on 10 per cent. solution of potass. ferro-cyanide and "fixed" in 1 : 25 sulphuric acid (specific gravity 1.84).

L. T.—If the dry plates have been kept in an unopened box and in a dry place, free from chemical fumes, they should produce passable negatives. The developing formula advocated is pyro-soda, viz.:—

No. 1 Pyrogalic acid	¼ oz.	25 gms.
Sulphuric acid	5 minims.	1.0 c.c.
Distilled water to make ...	10 ozs.	1,000 c.c.s.
No. 2. Carbonate of soda	2 ozs.	200 gms.
Sulphite of soda	2 ozs.	200 gms.
Potass. bromide	60 grs.	14 gms.
Distilled water to make ...	10 ozs.	1,000 c.c.s.

For studio use, 1 part of each and 2 parts of water (making 4 parts altogether) will be found about right. Such developer contains about 3 grs. pyro and 22 grs. each of carbonate and sulphite to each oz.

A. J.—Many bromide and gaslight papers will readily curl when laid down on the hand, the coated side assuming a convex shape. Also, the coated side, if one corner of a sheet of paper be touched with the moistened finger, will be felt as sticky, owing to the softening of the gelatine coating. A further method of telling the coated side is to go by the burred edge of the sheet, which usually stands up slightly from the film side. Still another method is to hold the paper bent in the form of an arch between the eye and the dark-room light. The line of light along the outer top of the arch or loop will indicate the nature of the surface. Glossy or semi-matt paper may be instantly recognised by its appearance. In the case of matt paper the emulsion side appears perfectly smooth and even, whilst, in comparison with it, the paper side has a distinct sheen. In the case of rough papers the emulsion side shows scarcely a trace of any line of light.

R. P. S.—Of the particular ways in which collodion paper is liable to give rise to failure the one which is least likely to be suspected is the tendency of the paper to develop yellow spots, or general fading of the image as the result of slowness in drying. This applies equally to prints which are trimmed wet and mounted at once. Whether unmounted or mounted, prints require to be placed so that they become perfectly dry within an hour or two. If they are mounted, the drying arrangement should be such that the mounts themselves also are not left retaining moisture. For this, mounts should be placed on a wire rack so that air can circulate freely round each and then put to dry in a warm, well-ventilated room. Once prints have become perfectly dry they seem to withstand the action of moisture perfectly well, collodion prints frequently withstanding moisture in outdoor showcases by no means rainproof without suffering in any way. The prints are also particularly liable to defacement by black spots mainly caused by minute particles of metal detached from metal cutting shapes, such as require to be used when trimming to ovals or circles. For rectangular prints the guillotine pattern of trimming board avoids this form of trouble.

F. M.—The method of making reversed negatives by ammonium persulphate, to which you refer, is as follows:—A lantern or other thinly-coated slow plate is placed in contact with the negative in a printing frame and a full exposure given such as would be thought advisable in making a soft positive transparency. The plate is developed with a clean working developer until the shadows appear quite black on the glass side of the plate. The time of development may be five times as long as for an ordinary transparency. The latter is then washed and placed in a 2 per cent. solution of ammonium persulphate until the silver image is seen to be removed. The plate is then thoroughly washed and developed in any clean developer containing about half a grain of bromide per ounce. It is then fixed and washed and dried. After the first development the operations may be done in weak daylight or artificial light. The action of the persulphate should be as complete as possible, otherwise a veil is left over the negative. Direct positives, but reversed from right to left, from engravings, etc., may be made in the camera by substituting bromide paper for the plate. The exposure should be full and the development as above. The method has this advantage, that the lines are rendered in the same degrees of black and grey as in the original, a point of some importance, since the lines in an engraving are seldom, if ever, of uniform blackness.

THE BRITISH

JOURNAL OF PHOTOGRAPHY.

No. 3252. Vol. LXIX. FRIDAY, SEPTEMBER 1, 1922. Price Fourpence.

Contents.

SUMMARY.

In a leading article we have something to say on the conditions in which a portrait photographer, who is working more or less without assistants, may take advantage of the services in printing, enlarging, etc., of the various trade firms. (P. 518.)

A cheap and easy form of electric lighting, using the Barkay reflector and reflected light, is dealt with by a practical worker who has forwarded us many beautiful examples of his work. (P. 519.)

Some hints on the photography of domestic interiors are given in a note on page 520.

Complaints of the quality of trade work which come before us almost invariably disclose the fact that the work was offered or advertised at an extremely low price. (P. 518.)

A problem of somewhat frequent occurrence in calculations relating to depth of focus is that of the distance upon which one should focus in order to obtain objects at given further and nearer distances in equally sharp focus—in other words, how to obtain the best distribution of definition. The formula for the distance upon which to focus is a very simple one, and also readily permits of ascertaining the lens stop which is required in order that the definition of the nearer and further points should conform to a given standard. An outcome of it is the series of consecutive depths of field sometimes used in depth focussing scales. (P. 521.)

In a paragraph on page 517 we refer to the exception, provided by the telephoto lens, to the rule that the camera back should be swung vertically when the camera as a whole is tilted.

Assistants' goodwill in their work is, we fear, often largely lost to a business by working conditions which involve great expenditure of what should be unnecessary labour. (P. 517.)

In the use of a reflex camera a short-focus lens may usefully form part of the equipment for the purpose of photographing, approximately same size, such subjects as pieces of mural writing, carving, etc. (P. 518.)

System in half-tone operating is the subject of an interesting letter from a Calcutta correspondent. (P. 527.)

"COLOUR PHOTOGRAPHY" SUPPLEMENT.

A French experimenter describes in a patent a photochromoscope and camera in which the three negatives are taken simultaneously. The apparatus is for viewing the additive colour effects as well as making the negatives. (P. 35.)

Some further reminiscences of commercial colour cinematography, with some notes on its possibilities, will be found on page 35.

Some up-to-date notes on Autochrome lantern slides are given on page 36.

EX CATHEDRA.

The Tilted Telephoto. Inasmuch as a fair number of lenses of the telephoto type are now in general use, it may be of service to draw attention again to one respect in which the telephoto lens differs from those of the ordinary type, since this concerns a point of practical procedure. As every photographer knows, in the use of a tilted camera it is necessary to swing the plate into a vertical position in order to obtain in the negative parallelism of vertical lines in the subject. There is, however, an exception to this time-honoured maxim. As was first pointed out some years ago by several users of the telephoto lens, with a lens of this type the back frame of a tilted camera requires to be neither in the vertical position nor in one at right angles to the base-board, but in a position intermediate between the two, as a condition of securing freedom from convergence of parallel lines in the subject. The observation of the practical workers has since been confirmed by the scientific optician, who has shown that this peculiarity is inherent in the telephoto type of lens. Now that fixed-focus telephoto lenses are sometimes sold without an indication that they are of the telephoto type, this caution may perhaps prevent the less-informed user from falling into the error that there must be something seriously the matter with his lens because it does not behave like one of the ordinary type in giving freedom from converging lines when the camera back is swung level.

* * *

Efficiency. Among employers of photographic labour there is, we fear, too often the tendency to regard the efficiency of an assistant as simply and solely a question of his or her competency in work. While there are always people who will misuse the best means which are provided to facilitate their work, we have very frequently observed conditions in photographic establishments which make highly efficient work an impossibility. Many employers require to realise that it is destructive of the assistant's good will and cheerfulness in his work that the arrangements should necessitate a large proportion of what should be unnecessary labour. In highly-organised industries on the large scale an immense amount of thought is given to the elimination of unnecessary labour, and the same degree of attention is required in the smaller establishments, such as those engaged in the making of photographs. Yet, to cite a state of things which we have several times seen with our own eyes, an enlarging apparatus will be installed on a different floor from that where the dark room is situated. As a result, as much time is spent in running to and fro for making test exposures and for exposing the full size sheet of paper as would suffice in compactly arranged premises for doing the whole job. Yet, a bad arrangement of this kind would be defended for the strange reason that it had been in use for twenty years. Very often inefficient organisation of this kind goes hand-

in-hand with long working hours. The two together are responsible for a condition of persistent fatigue among the assistants by which their ability progressively decreases to a low ebb. We are convinced that there are many employers who have much to gain by critically scrutinising their working arrangements, even though these may have been devised by themselves, say, ten years ago.

* * *

Reflex and Short Focus Lens. Perhaps the one respect in which the reflex camera fails those who would possess a hand camera having all the movements of a stand instrument is that the lens is necessarily of focal length a little greater than the long side of the plate, in order to allow room for the movement of the mirror. Hence the use of a wide-angle lens is a facility which is denied the reflex worker, at any rate for the normal operation of the camera. A Chinese inventor not long ago proposed to get over the difficulty by a device which was much more clumsy than the really elegant construction devised many years before by the late Mr. A. L. Adams, who caused the mirror to move down instead of up, and provided a blind to cover the focussing aperture. Even so, if special importance is attached to the use of a short-focus lens, the readiest plan is to fit it in a deeply-sunk mount and to keep the mirror up, focussing on a ground glass behind the shutter and dispensing with the use of the mirror. As such wide-angle photographs are usually required of still subjects, little is sacrificed by the use of a tripod when operating in this way. For another purpose, however, the short-focus lens is very useful in the normal employment of a reflex, viz., for copying same size with the camera held in the hand. We have often used a 3-in. lens on a quarter-plate reflex when photographing bits of mural writing, coins, and similar subjects approximately full size, and could wish for no better or more expeditious camera for such work.

* * *

Prices and Quality. The economic fact that prices of goods find their level in relation to their quality is one which, so it would appear, is scarcely realised by many of those who have dealings with firms offering trade work in the shape of prints, enlargements, etc. It is within our experience to receive from time to time complaints of the quality of enlargements or post-cards which have been executed to a photographer's order by one or other of the trade firms. Almost invariably, on the complaint being investigated, it has turned out that the work has been done at extraordinarily low prices. In these circumstances the buyer should certainly have realised that if he takes the risk of a price which may be a quarter of that charged by a first-rate firm, he cannot expect to be assured of a first-rate quality. In exceptional cases, as, for example, where a good trade worker is starting by his unaided labour and is seeking to attract customers by the indiscreet method of offering exceptionally low prices, the work may be astonishingly good at the price. But such discoveries must be few and far between; and almost inevitably a man who starts in business on this basis has to raise his prices as soon as his trade reaches such dimensions that he requires to employ assistants of skill comparable with his own. It requires to be borne in mind that an important difference between low-price and high-price firms is that the charges made by the former do not permit of unsatisfactory work being thrown out; instead, it has to be supplied to the customer. This distinction is probably a more frequent cause of unsatisfactory work than the use of poorer materials or cheaper labour. The low-price man, from his circumstances, is compelled to work to a price, whereas the charges of the high-price man allow him to work to his standard of quality.

THE USE OF PHOTOGRAPHIC TRADE SERVICE.

The long establishment of that branch of the photographic trade which undertakes printing, enlarging and finishing for portrait photographers may be taken as a sign that this service is widely employed and valued by photographers generally, and hence some notes on the best way of using these facilities may be of service to some making a start in studio portraiture and not so familiar as they should be with the measures to adopt in utilising the trade houses.

Generally speaking, this trade service is employed on one or other of two plans. One is to let the outside firm do as little as possible. The other is to let it do as much as possible. Naturally, there are degrees in the adoption of either plan, but the photographer, who, for example, is starting in portraiture "on his own" may well consider in which of these two directions he shall endeavour to work. If in the first, he will need to make provision for his printing, enlarging and finishing himself, or by means of a staff as his business grows, and will rely upon the trade firm for those special jobs which are beyond the scope of his facilities by reason of their nature or magnitude. On the other hand, if the plan be adopted of utilising a trade service to the utmost degree, the embyro portraitist is able to consider making his equipment of the simplest kind, and may perhaps be thereby enabled to take premises which otherwise would be impossible for his purpose. Although his prints, etc., may cost him more than if produced on the spot, he is relieved from the anxiety of keeping assistants employed when there is not enough for them to do, and, moreover, will almost certainly be able to draw upon a variety of work, such as he could not unaided expect to offer to his customers.

Those who follow the first of these plans, that is to say, make occasional use of the trade house, must be prepared for certain difficulties. It cannot be expected that the trade worker should be able by intuition to realise in what particular way an order is to be carried out, and the portraitist may easily receive a shock on the delivery of prints which he thinks much too dark, or too light, or in some other way a departure from his accustomed standard. In such circumstances as these his best course is to use the trade firm only for fairly large numbers, from a dozen upwards, and on no account to omit sending, with each negative, a finished print showing exactly what he wants. And plainly, in any circumstances, it is useless for him to expect satisfactory work at a cut price; he must be prepared to pay a price which will allow the trade firm to throw out prints which are not first-class, and, moreover, to permit the employment of experienced artists for the finishing and colouring. We sometimes receive complaints of the work turned out by trade houses, and are coolly requested to expostulate with them on supplying prints of such inferior quality. Almost without exception in such cases it transpires that the work is being done at the most miserable cut price, representing little more than a narrow margin on the cost of materials. Provided a decent price is paid and, what is equally important, plainly expressed typewritten instructions given to the trade house, preferably accompanied by a specimen print, to serve as a guide for vignetting, worked-in back-

ground, etc., the intermittent user of a trade service should have no difficulty in making valuable use of these facilities.

As regards the regular employment of a trade house for the great bulk of printing and enlarging work, probably the most favourable condition for this plan is the supply of clearly sighted well-finished portraits, such as form the output of a good middle-class business. The photographer will be well advised to adapt his style to that of the trade house. Such a course promotes the prompt delivery of work up to a certain standard, and a fairly high one at that, and eliminates a great many sources of misunderstanding. At the same time it must not be supposed that a trade house undertaking the regular work of a studio is unable to maintain a particular style and standard, agreed upon at the outset; such, in fact, is the arrangement which is regularly being carried out with satisfaction to both parties. The most prolific causes of delay and disappointment are almost inevitably the request for special tones, particularly in the case of small batches of prints. There is also the further motive in establishing regular relations with a trade house, namely, the opportunity which is naturally afforded for such customers to receive preference in being shown the firm's latest styles in finishing and colouring. As we have pointed out on previous occasions the photographer in a small town may often make extra sales of portraits, and at the same time add to the attractiveness of his displays, by ordering a few "speculative" portraits from his trade supplier.

INEXPENSIVE ELECTRIC LIGHTING FOR THE STUDIO.

The darker half of the year is fast approaching, and many photographers—particularly those in a small way of business and with no artificial light installation—will be turning their attention to the problem of taking portraits by the aid of gas or electric light, and my experiences with a simple form of electric light may be of some service.

I am a great admirer and a user of the Barkay reflector, which I believe is not in general use, as it deserves to be, among professional photographers who have electric light laid on. I find the reflector to be an ideal accessory, as I have no great love for the spot light. When first using the reflector, I was perhaps a little too impatient—as all who try it for the first time may be—but the system was quickly mastered, and the results obtained when using a single 1,500-c.p. half-watt lamp in conjunction with the reflector are extremely satisfactory. I get a satisfying and comforting kind of light, of the kind that minimises all worry about exposure with nervous subjects, children, or babies. It is a powerful light, but one that is surprisingly soft and subdued.

At present I am getting with this lighting beautifully illuminated and fully exposed negatives on orthochromatic plates of H. and D. 400, 500, 550 and 600 speeds, with a maximum of one-quarter of a second's exposure.

For small work I have in use a modern anastigmat lens of 5½-inch focus and working at f/4.5, and for postcard size and cabinets I have another anastigmat of 8¼-inch focus and working at f/5.6. I stop down the latter, however, to f/6.5 for groups, and expose by opening and closing the shutter as quickly as possible, this being the longest exposure I give at any time. The resultant negatives are invariably crisp, full of detail, and have finely graded half-tones—in short, all that could be wished. My earliest efforts with the light were not very satisfactory, because—like everything else—the use of the reflector must be fully understood before one can secure the finest results.

The reflector was installed early in April last, and I chose the No. 4 model, hanging from the ceiling, the reflector being of the H type. It was first used as a direct light, as I believe it is commonly used, using butter muslin as a screen between light and sitter, but the results were not what I required. Light was enormously increased, but the negatives I secured were a little too hard, and the light much too bright, and very uncomfortable for the sitters, because of an enforced nearness on account of limited space. It was next tried with blue tracing linen as a screen or filter, and this was a decided improvement, and one which gave a much softer effect both in the lighting and the negative, but still rather trying to the sitter's eyes. The next experiment was to have the wall against the light covered with a white paper having a silvery sheen; the lamp and reflector were then reversed (the reflector being between the sitter and light), and the light reflected from the papered wall used in place of direct light. This arrangement was a great success, as the light spreads everywhere with a soft and subdued radiance, and does not dazzle the eyes of the sitters.

The fitting allows of the light being moved or adjusted very quickly to any requirement. The pendant-fitting is 58 inches

Fig. 1. Portrait taken by reflected light from the Barkay reflector. Stop F. 5.6; plate, isochromatic, H. & D. 500; exposure, ½ second.

long, and consists of four sections (three hinges), each of which swings through an arc of 330 degrees at right-angles to the one above, the two longer arms rotating in their own length, thus reaching any point within the hemisphere, making it suitable—when used in the ordinary way—for high or low lights, front, side or back lights.

Mention is made of four different plate speeds used because I am experimenting very extensively with different makes and

speeds, making notes and comparisons with a view to making a final and decisive choice of a plate that I shall use and keep to. All are good, but I want the best.

With this reflector a certain amount of caution is advisable, and the operator must always see that the illumination is even, especially in the lower front part of the field of vision, otherwise a little local under-exposure may perhaps be met with, but still nothing that cannot be dodged in the printing. With this reflected light there is little or no retouching required in small work, and very little on postcard and half-plate negatives.

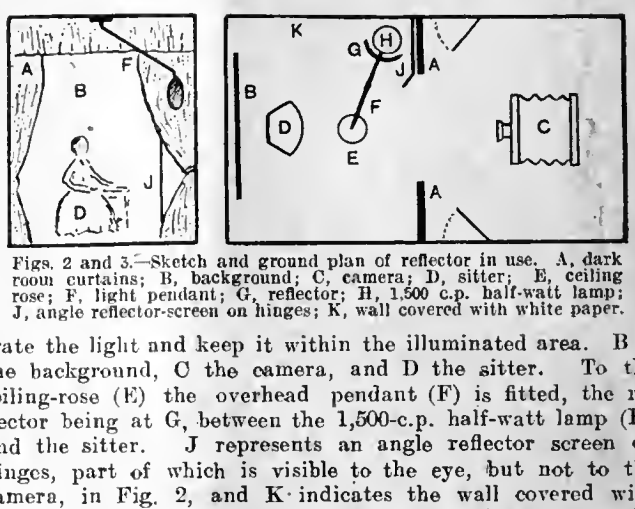
The overhead No. 4 model is certainly a most useful fitment; and I can only suggest that universal joints would be a great improvement, as they would enable the operator to turn the arms to any position required, using only the hand and without having recourse to either wrench or pliers.

The makers of the reflector claim that it increases the light by upwards of 800 per cent., which is, to my mind, a very moderate estimate. My studio is a small room, and the light can be even more concentrated by means of curtains and a hinged reflector, as shown in the diagrams.

The H-type reflector is really a spot light fully extended, and is very brilliant. No electric light studios can afford to ignore the advantages offered by the use of these reflectors, as by their means operators can either increase their present lighting some hundreds per cent. at no extra cost, or they can do away with three-quarters of their lamps and yet have a more powerful light.

The reflector turns a good light into a super light, and work is improved accordingly. Unless the lighting be seen, it is almost impossible to realise how soft, and yet powerful, it is.

Fig. 1 is a child portrait taken by means of reflected light; *f*/5.6 was used, and a quick "open and close" shutter exposure given, approximately one-quarter of a second. Fig. 2 gives an idea of how the setting appears to the operator when at the camera, and Fig. 3 is a plan of the studio. In Figs. 2 and 3 the fittings are indicated by reference letters, as follows: A, dark curtains at side and top of opening to concentrate the light and keep it within the illuminated area. B is the background, C the camera, and D the sitter. To the ceiling-rose (E) the overhead pendant (F) is fitted, the reflector being at G, between the 1,500-c.p. half-watt lamp (H) and the sitter. J represents an angle reflector screen on hinges, part of which is visible to the eye, but not to the camera, in Fig. 2, and K indicates the wall covered with white paper with a silvery sheen, a medium which reflects the light and makes it possible to secure well-exposed negatives under the very simple conditions described.



Figs. 2 and 3.—Sketch and ground plan of reflector in use. A, dark room curtains; B, background; C, camera; D, sitter; E, ceiling rose; F, light pendant; G, reflector; H, 1,500 c.p. half-watt lamp; J, angle reflector-screen on hinges; K, wall covered with white paper.

THE PHOTOGRAPHY OF DOMESTIC INTERIORS.

[Many helpful hints are contained in the following article, which we reprint from our Philadelphian contemporary, "The Camera." Although written primarily for the amateur, who is supposed to know little or nothing of the photography of domestic interiors, the professional worker will find many useful hints and reminders which will be of service in practical work.]

The chief thing in arranging an interior for the camera is to make things look "as if they had not been arranged, but are just as they usually are." A pipe laid across an open book, an open letter and torn envelope, a hat and gloves, an open work-basket, these and half a score similar objects will suggest themselves to the reader as personal touches indicating that the room is not a "withdrawing" room for state occasions, but a living room in daily use.

There is no hard and fast rule as to lighting, but as a very general and practical guide we may say that the most picturesque effect will not be obtained when the sun is exactly in front of the window. With the sun a little to one side or the other we get an oblique and far more pictorial and interesting effect.

Bear in mind that the lens tends to exaggerate and distort the objects nearest to it. A small round table near the lens and appearing in the corner of the foreground will probably come out far too large, and, perhaps, oval in shape. To move the table from its accustomed place and away from the camera will probably give an unusual arrangement and also make the room look crowded and arranged, but if omitted altogether its absence will not be detected.

The point of view is most important. The commonest fault is pointing the lens into the opposite angle or corner of the room. This gives us a vertical line down the middle of the print. If one side of the room is darker than the other, then point the lens slightly toward the darker side. The next fault is having the lens too high above floor level. The smaller the room the lower the view point is a good rule, and 42 inches to 5 feet will be found a useful working margin.

The best thing to prevent tripod points slipping is a rug or carpet on which to stand the tripod. If these cannot be obtained, then use a long piece of string and give it three or four turns round each leg about six inches from the ground, and then tie the ends of the string.

As a good deal of furniture has a polished surface, and as these glittering patches yield spotty lights in the picture, we must always be on the watch to guard against them as far as possible. Very often a glittering light can be got rid of by moving the article an inch or two. Picture frames and their glasses are a great nuisance in this way. A wine cork or a handful of crushed-up newspaper placed between the frame and the wall will usually give it enough tilt to get rid of the glitter. Chimney pieces, ornaments, fire irons and all like things need watchful attention. Bear in mind that an object may show a bright reflecting surface when you see it from one position and not do so when viewed from some other position. Having got the view point fixed, unscrew the lens, throw back the focussing screen and look at the subject through the hole of the lens flange. It may happen that some of the reflections you have been troubling about do not appear from this point of view, while others previously unnoticed show themselves. This plan of direct inspection is better than trying to see and locate them from the ground-glass inverted picture. It is easier, quicker, and far more certain, but do not forget to view all the picture by putting the eye to all the four corners of the back opening of the camera.

We may take it as a good general rule that the farther we can get away from the subject the better proportions and perspective we shall get. It may not occur to everyone to view the subject from outside the room itself, *i.e.*, through the chink of a half-open door. But very often this gain of an extra foot or two makes a good deal of difference. In the case of a two-windowed room on the ground floor or on an outside balcony we may sometimes stand the camera outside one of the windows.

A lens of moderately short focus is generally necessary for this kind of work, but it is quite a mistake to go to extremes. A good general guide is such cases is to have the focal length of the lens intermediate between the length and breadth of the plate. Thus for a quarter-plate the focal length may be between 3½ and 4½

inches, preferably nearer four than three inches. We often notice in small interiors an up-hill look about the floor. This is due to the use of the lens too high up above floor level. If the tripod has not got sliding legs to bring the camera to about three or three and a half feet from the ground, then a small table can be used as a camera stand. Sometimes the camera can be put on a bookcase, shelf, or mantelpiece, and so get the lens farther away from the object than it would be if a tripod be used.

As to exposure and development the best plan is to follow the well-proved rule of exposing for the shadow and developing for the high lights. Most interior negatives are under-exposed. This probably results from the necessary employment of a small stop to get the required details, and again the eye does not adequately realise the strong light and shade contrasts in most cases. In rooms with small windows, if the walls are not already of a light colour it will be found very advantageous to fix up a white sheet or tablecloth on the wall opposite the window (and, of course, out of the view). This acts as a reflector and diffuser and saves the dark corners from becoming as detailless clear glass in the negative.

Most interior negatives are over developed, and this tends to accentuate further the contrasts which under-exposure has already emphasised. The best kind of developer for interior work is one which brings out all the image quickly and then builds up density contrasts gradually. For this purpose Azol and similar developers freely diluted are to be preferred. When in doubt it is better to over rather than to under expose, as prolonged development will generally give enough contrasts unless the exposure has been very much over done. Similarly it is better to under rather than over develop, because intensification will easily give us added contrasts; but it is not an easy matter to reduce without losing some of the shadow detail and lower tones, or alter the gradation. In all kinds of interior work the shadows are nearly always far more important than the high lights, and special attention should at all times be given to them.

THEORY AND PRACTICE OF DEPTH OF FOCUS.

IV

[If objects at, say, 6 ft. and 20 ft. from the lens are required equally sharp in the negative, on what distance should one focus? The formula for problems of this kind is shown in the present chapter, in which also are given formulæ for ascertaining the diameter of a stop or the nominal F. No., which requires to be used in such circumstances, in order that the degree of unsharpness of the images of objects at the prescribed distances shall not exceed a given value. An allied question is the devising of a series of distances, which may be marked on the focussing scale of a hand-camera, such that (by focussing on any one of them) far depth extends to the next greater and near depth to the next smaller.]

The Distance to Focus On.

A PROBLEM of occasional occurrence is: on what intermediate point shall one focus in order that a nearer and a more distant object shall be rendered in the same degree of unsharpness, so that the best distribution of focus shall be thereby obtained in the negative?

Fig. 7 again represents the construction in the image space which yields the formula for the required distance on which to focus. As

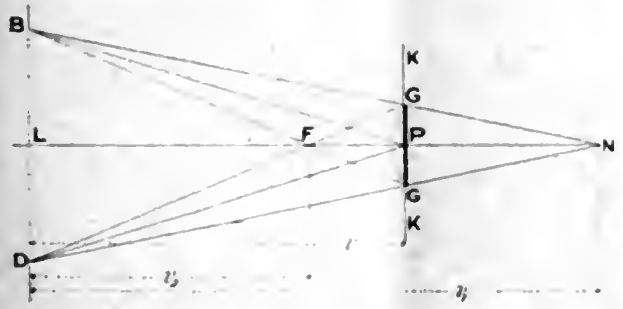

Fig. 7.—Illustrating images F and N of furthest and nearest objects to which depth extends when focussing on a given object. P is the point of the object in sharp focus. F is the image of the further object and N of the nearer, the cross-section of pencils from each being $G\,G = c$ in the plane of the focussing screen $K\,K$.

before, $B\,D$ represents the diaphragm and $L\,F$ the lens axis. N is the focus of rays from the nearer object at a distance u_1, and F that of the further object at the distance u_2. It is clear that the plane $K\,K$ in which the pencils of rays from u_1 and u_2 have the same cross-section is the focus of the distance required. This distance u can be expressed simply in terms of the distances u_1 and u_2.

From the triangles $B\,F\,D$ and $G\,F\,G$,

$$\frac{L\,F}{F\,P} = \frac{B\,D}{G\,G}$$

But $F\,P = L\,P - L\,F = v - v_2$.

Therefore $$\frac{v_2}{v - v_2} = \frac{B\,D}{G\,G}$$

Similarly from the triangles $B\,N\,D$ and $G\,N\,G$

$$\frac{L\,N}{P\,N} = \frac{B\,D}{G\,G}$$

But $P\,N = L\,N - L\,P = v_1 - v$.

Therefore $$\frac{v_1}{v_1 - v} = \frac{B\,D}{G\,G}$$

Therefore $$\frac{v_1}{v_1 - v} = \frac{v_2}{v - v_2}$$

whence $$v = \frac{2v_1 v_2}{v_1 + v_2} \qquad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \quad (a)$$

The three image distances, v, v_1 and v_2, are respectively equal to:—

$$v = \frac{fu}{u - f} \qquad v_1 = \frac{fu_1}{u_1 - f} \qquad v_2 = \frac{fu_2}{u_2 - f}$$

Substituting these values of v, v_1 and v_2 in equation (a) we get:—

$$u = \frac{2u_1 u_2}{u_1 + u_2} \qquad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \quad (15)$$

In words, *the intermediate distance upon which to focus in order to obtain an equal degree of unsharpness in the images of a nearer and more distant object is equal to twice the product of the two given distances divided by their sum.*

For example, objects at 80 in. and 240 in. are required equally defined. Distance on which to focus is therefore:

$$\frac{2 \cdot 80 \cdot 240}{80 + 240} = \frac{80 \times 240}{320} = 120 \text{ in.} = 10 \text{ ft.}$$

It is clear that formula (15) is independent of the focal length of the lens, the size of the diaphragm, or the standard adopted for the disc of confusion. The formula is strictly limited to giving the distance on which to focus for an equal degree of unsharpness in the images of objects at the specified distances. If the degree of unsharpness is too great to be permissible, the use of a smaller stop will reduce it equally as regards the image of both the nearer and more distant objects.

The stop which is necessary in order to obtain a disc of confusion corresponding with any chosen value of c for the images of objects at u_1 and u_2 when focussing on u can now be found from a modification of formula (7) or (9).

Stop required for required near or far extension of depth when focussing on a given distance.

As is evident from its form, formula (15) gives only the distance u on which to focus in order that the best distribution of "focus" may be obtained between a nearer object u_1 and a further object u_2. It does not tell the stop which requires to be used in order that the disc of confusion at u_1 and u_2 shall not exceed a given value.

The actual diameter of stop or, alternatively, the F. No. can, however

be found by suitable transformation of either formula (7) for the near distance to which depth extends or formula (9) for the far distance.

From formula (7), if we focus on an object at a distance u with a lens of focal length f, and diaphragm d, and adopt a disc of confusion of diameter c, depth extends to a distance u_1 from the diaphragm, eqnal to:

$$\frac{fdu}{fd + c(u - f)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

In the case that we know both u and u_1 (the former having been found from formula 15), formula (7) can be written so as to give the value of d in terms of these distances, and of f and c. Converted in this way, formula (7) becomes:

$$d = \frac{cu_1(u - f)}{f(u - u_1)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16)$$

In words, *to find the actual diaphragm diameter required for "focus" up to a certain near distance u_1 when focussing on a distance u, subtract one focal length from the distance u, multiply by the distance u_1 and by the diameter of the admitted disc of confusion. Divide the result by the local length of the lens, and also by the difference between u and u_1.*

If the disc of confusion be taken as 1-200th of an inch, the above formula becomes:

$$d = \frac{u_1(u - f)}{200f(u - u_1)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16a)$$

The formula may also be written so as to yield the *F. N°* (nominal f/d) which requires to be used under the same conditions:

$$F.\ N^\circ \text{ (i.e. } \frac{f}{d}) = \frac{200f^2(u - u_1)}{u_1(u - f)} \quad . \quad . \quad . \quad . \quad (16b)$$

In words, *multiply the focal length by itself, by 200 and by the difference between u and u_1 and divide the result by u_1 and by u less one focal length.* This formula gives the correct *nominal F. N°* (f/d not v/d) to which the lens must be set to secure the required degree of sharpness. The exact number so obtained is not likely to be marked on the lens unless a very finely sub-divided scale has been specially engraved for the purpose. In practice, the lens will advantageously be stopped down to the nearest smaller stop, or higher *F. N°* marked on its mount; or, if shortness of exposure is a consideration, a special diaphragm may be cut to the size indicated by formula (16) or (16*a*).

These formulæ in all three forms apply to objects at any distance, but as a rule they are of service only in calculations relating to the making of relatively large scale photographs of near objects, in which circumstances considerable sharpness is required. For this reason a disc of confusion of 1-200th of an inch has been chosen for (16*a*) and (16*b*).

For smaller values of u, i.e., when the object is near the lens, the effective or exposure value of the stop so determined will be reduced in consequence of the increase in the camera extension v or distance between lens and plate. (The time of exposure with a stop of any given diameter is of course directly proportional to the square of the camera extension, or varies directly with the area of the surface over which the light entering the lens from the objects is spread on the plate.) It is useful, therefore, to know the effective value of the stop for exposure purposes, and this may be found by multiplying the *nominal F. N°* by $\frac{u}{u - f}$, or by $r + 1$, where r is the ratio of negative to object, i.e.:

$$\text{Effective } F.\ N^\circ = F.\ N^\circ \times \frac{u}{u - f}, \text{ or } = F.\ N^\circ \times (r + 1)$$

For example, an object is to be photographed natural size, and the *F. N°* to which the lens must be set has been found by formula to be *f*/22. Here r, or ratio of negative to object = 1. Therefore the effective exposure value of *f*/22 will be 22×(1+1) or 44. Exposure must be given as if the stop in use were *f*/44, and the time required will be four times that which would be sufficient when taking a distant object with the same stop.

Again, an object 20 in. distant is to be taken with a 6 in. lens, working at *f*/16. The effective *F. N°* of the stop will then be $16 \times \frac{20}{20 - 6}$, or nearly 23, and the exposure will be more than double that normally required with *f*/16.

The above formulæ for the diaphragm may equally be expressed in terms of the far distance u_2 obtained in "focus" when focussing sharply on a distance u_1 in which case they are:—

$$d = \frac{cu_2(u - f)}{f(u_2 - u)} \quad . \quad . \quad . \quad . \quad (17)$$

$$d = \frac{u_2(u - f)}{200f(u_2 - u)} \quad . \quad . \quad . \quad . \quad (17a)$$

$$F.\ N^\circ \text{ (i.e. } \frac{f}{d}) = \frac{200f_2(u_2 - u)}{u_2(u - f)} \quad . \quad . \quad (17b)$$

When considerable magnification of the object is required the total depth distance ($u_2 - u_1$) obtainable in sharp focus will be small, as the *F. N°* calculated from the formulæ rapidly becomes impossibly high, or, in other words, the stop diameter required soon passes the limit of practicable smallness.

Diaphragm for Near and Far Depth Distances in Terms of Variable Disc of Confusion.

It remains to derive the formula for the diaphragm required for depth distances of u_1 and u_2, when focussing on u, from the standpoint that the diameter of the disc of confusion may be a certain small fraction, e.g., 1-2,000th, of the viewing distance. In formula (16), viz.:

$$d = \frac{cu_1(u - f)}{f(u - u_1)},$$

let us replace c by an expression representing 1-2,000th of the image distance (which should be the viewing distance) of an object at a distance u. The corresponding image distance, from the law of conjugate focal distances, is

$$\frac{fu}{u - f}$$

so that we will take c as $\frac{fu}{2{,}000\ (u - f)}$.

Substituting this value of c in formula (16), we get

$$d = \frac{u}{2{,}000} \times \frac{u_1}{u - u_1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (a)$$

From formula (15),

$$u = \frac{2u_1u_2}{u_1 + u_2}$$

Substituting this value of u in the latter part of (*a*), we get

$$d = \frac{u}{2{,}000} \times \frac{u_2 + u_1}{u_2 - u_1} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (18)$$

That is to say, from the standpoint that the admissible disc of confusion is a small fraction of the viewing distance, the actual diameter of diaphragm required for limiting the unsharpness of objects at distances u_1 and u_2 when focussing on u is found by multiplying the sum of u_2 and u_1 by u and dividing the result by the difference between u_2 and u_1 and by 2,000 (assuming 1-2,000th as the angle of sharpness of vision).

Consecutive Depth of Field.

A question of some practical importance is:—Can there be devised a series of distances u_1, u_2, u_3, u_4 from the camera such that, if sharp focus be obtained on any one of them, depth extends forwards to the next greater and backwards to the next smaller? For example, if u_1 is the smallest and u_4 the greatest of the four distances, can we devise them so that when focussing on u_2, far depth extends to u_3 and near depth to u_1; and when focussing on u_3 far depth extends to u_4 and near depth to u_2?

It can easily be shown, both by geometrical construction and by formulæ (8) and (10), that the above requirement cannot be fulfilled *exactly* by any series of distances. It was, however, pointed out by C. Welborne Piper ("Amateur Photographer," Vol. 26, Sept. 27th, 1897, p. 252) that a certain series of distances possesses the above property with quite sufficient approach to exactness for practical purposes. This series (in the inverse order of magnitude) is: the hyperfocal distance; half the hyperfocal distance, one-third the hyperfocal distance, and so on; which may be written as

$$\frac{H}{1} \quad \frac{H}{2} \quad \frac{H}{3} \quad \frac{H}{4} \quad \frac{H}{5} \quad \frac{H}{6}$$

Actually the distances are not limited to this particular series. They may be any distances obtained by successively dividing the hyperfocal distance by numbers in arithmetical progression, that is to say, numbers differing from each other by the same amount. In the above series the common difference of the divisors is 1, but it could be any other number. The above series, however, provides about the most useful series of distances. For example, with a 6-inch *f*/8 lens (hyperfocal distance, 38 ft. for disc of confusion of 1-100th of an inch) the distances are approximately:—

38 ft., 19 ft., 13 ft., 9 ft. 6 in., 8 ft., 6 ft., 5 ft.

Thus, when focussing on 19 ft. with *f*/8 depth extends from 38 ft. to 13 ft., when focussing on 13 ft., it extends from 19 ft. to 9 ft. 6 in.

The degree to which the depths of field are approximate can be demonstrated by making use of formulæ (8) and (10). If for u in these formulæ we write $H/2$ it will be found for example that the nearest and furthest distances of depth differ very slightly from $H/3$ and H, respectively. A still simpler device is to replace u in these formulæ by $H + f$, $\frac{H}{2} + \frac{f}{2}$, etc., and by $H - f$, $\frac{H}{2} - \frac{f}{2}$, etc., when the following results are obtained. (Table III.)

TABLE III.

Furthest distance from camera to which depth extends.	Focus on	Nearest distance from camera to which depth extends.
—	infinity } i.e. $\frac{H}{\infty}$	H
infinity . . .	$H + f$	$\frac{H}{2}$
	$H - f$	
H	$\frac{H}{2} + \frac{f}{2}$	$\frac{H}{3}$
	$\frac{H}{2} - \frac{f}{2}$	
$\frac{H}{2}$	$\frac{H}{3} + \frac{f}{3}$	$\frac{H}{4}$
	$\frac{H}{3} - \frac{f}{3}$	

It will be seen from this table, which represents mathematically and geometrically exact results, that in order to cause *far* depth to extend to the hyperfocal distance, we require to focus not on half this distance, but on half the hyperfocal distance *plus* half the focal length of the lens; and for *near* extension of depth to one-third the hyperfocal distance from the camera, the theoretical distance on which to focus is half the hyperfocal distance *less* half the focal length of the lens; and in like manner in the other cases. But in every case the odd focal length or fraction of a focal length is very small compared with H or $H/2$, etc., and may be neglected, so that the distances which are bracketed together in the table may be taken as H, $H/2$, $H/3$, and so on. The effect of such approximation is to give a certain amount of overlapping of the depth of field, a feature of the system which is an advantage from the practical standpoint.

Distances devised on the foregoing system have been recommended for the marking of the focussing scale of a hand camera. If this is done the graduations on the scale are equally separated by a space which, for a disc of confusion of 1-100th of an inch at the far and near depth distance, is equal to the $F.N$ of the full aperture divided by 100. The H mark (= 38 ft. in the above example) is made at this distance beyond the infinity mark. This rule again, while not theoretically exact, is sufficiently near to the truth for practice, under the ordinary conditions of focussing by visual judgment of distances. The degree to which the rule departs from truth may be seen by calculating the image distances of the object distances H, $H/2$, $H/3$, etc., and subtracting each from the next larger, the image distances corresponding with H, $H/2$, $H/3$, being $\frac{fd}{d-f}$, $\frac{fd}{d-2f}$, $\frac{fd}{d-3f}$, etc.

For example the space between the $H/4$ and $H/5$ mark for an 8-inch $f/8$ lens (H = 68 ft.) is .088 of an inch instead of .080 inch obtained by dividing the $F.N$ by 100. It is obvious that the size of the space between each mark is proportional to the $F.N$ of the lens. Hence, with lenses of aperture N smaller than about $f/8$, the graduations of such a consecutive scale are much too close together to be convenient. For this reason depth focussing scales have proved of little use in practice with modern large-aperture lenses.

E. E. B.

A COMPETITION for amateur photographers is being organised by the Southgate District Chemists' Association in aid of the Royal Northern and Passmore Edwards Hospitals. Photographs must be taken at a fête at Broomfield Park, Southgate, on Saturday, September 16. Rules, conditions and entry forms are obtainable from photographic dealers in Southgate. Mr. Gerald M. Bishop, managing director of Amalgamated Photographic Manufacturers, Ltd., will act as judge.

Photo-Mechanical Notes.

Half-tone Screens.

SOME time ago some notices appeared in the technical press respecting a new form of the half-tone process which, it was plain, very greatly simplified the working. It would seem that the basis of the method is the form of half-tone screen, particulars of which have now been published in a patent specification granted to J. A. H. Hatt, 22, East 89th Street, New York. The following is the chief part of this specification, No. 170,270.

One form of the invention is illustrated in the drawings, in which fig. 1 illustrates one element of the screen of fig. 3 and fig. 2 the corresponding other element of the screen of fig. 3, while fig. 3 represents the complete screen; fig. 4 is a section on the line 4-4, fig. 3.

In order to prepare this form of the improved screen, a number of glass plates are coated with a sensitized film, preferably a bichromated colloid. The coating is preferably of the type in which the sensitized film upon the glass, in so far as it is not acted upon by rays of light, shall be capable of ready removal therefrom. A regular cross line screen is then required, *i.e.*, a standard screen or a special screen such, for example, as the one which comprises two glass plates each ruled in such a way as to have clear glass strips of substantial width alternating with strips composed of a series of parallel closely spaced ruled lines, the two glass plates being superposed in such a way that the ruled lines cross each other at right angles. This screen is placed in front of one of the glass plates sensitized as described. A plain sheet of glass will usually be required between the screen and the sensitized glass plate in order to secure the proper "screen distance," which may be defined as the distance which produces a round dot on the sensitized plate through the rectangular, clear glass openings of the screen. After being placed in a printing frame, the plate is then exposed to an arc light. By varying the time of exposure this round dot may be made larger or smaller at will. The plate is now developed, for instance, by being immersed in water, and the round dot image which remains is dyed until it is quite black or opaque. The dyeing can be done by aniline dyes. The result of this treatment is illustrated in fig. 1, in which the glass plate 1 is coated with a series of spaced opaque dots 2. The space between the dots is not covered by a film but is clear glass.

This plate of fig. 1 is then used for the purpose of making the other half of the screen. The plate of fig. 1 is brought into contact with a second sensitized plate similar to the one from which fig. 1 was prepared and exposure made. The second plate is then developed in the same manner as the first, and it is also dyed, but to a different degree. The same dye that was used in making the first plate can be used in making the second plate, but the second plate must be left in the bath a shorter period of time or the dye bath must be diluted or a specially prepared dye bath may be used, the result being, in either case, to produce a translucent field 3 inter-spaced with clear glass openings 4, the latter corresponding in this particular method of producing the second plate to the position of the dots 2 of fig. 1. The feebly opaque part 3 of fig. 2 may be described as "translucent." The effect to be obtained is that the translucent portions 3 shall, to a certain extent, obstruct the free passage of light, but shall, nevertheless, when the light is intense, permit it, or a part of it, to pass through. The two plates, that is, the plates of fig. 1 and of fig. 2, are then placed together in such a manner that the clear glass 4 of fig. 2 and the opaque dots 2 of fig. 1 do not overlap, but are arranged, *e g*, in quincunx order. The result is shown illustratively in fig. 3, in which is illustrated a complete screen, which consists of three portions, first a general ground of translucent film 3, and upon

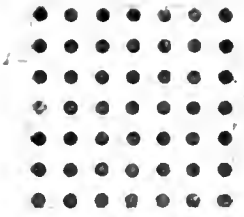

Fig. 1.

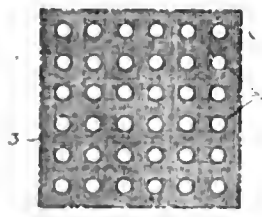

Fig. 2.

that ground interspaced throughout the entire surface of the screen a series of clear glass openings 4 and a series of opaque dots 2.

From the foregoing description it will be readily observed that instead of proceeding as described, master negatives for the production of these screens may be made by almost any photographic process. It must be observed, however, as already pointed out, that in order to make a satisfactorily working screen of proper optical qualities, it is essential that no film be allowed to remain over the clear glass portions of the screen, and that when a photographic process is used, it must be one which will leave no such film over the clear glass portions. The film, even if transparent, seems to diffuse the light and prevents it focussing properly, and, consequently, acts to prevent the formation of the "hard dot" which is required. In placing the two plates 1 and 2 in proper juxtaposition to form the complete screen of fig. 3, the two plates may be

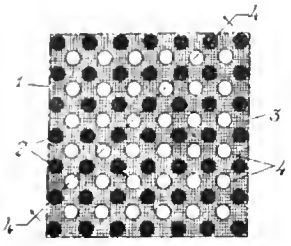

Fig. 3.

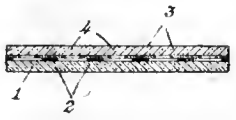

Fig. 4.

either placed directly together, as shown in fig 4, or they may be slightly spaced apart to form what is known as an "air space screen," the advantages of which are set forth in J. A. H. Hatt's Patent No. 14,393 of 1913. ("B.J.," 1914, March 13, p. 200).

In the employment of the screens it is preferred to use two plates, one of which (fig. 2) consists of a translucent film with small round clear glass openings interspaced there through. The clear glass openings of this plate occupy approximately the same positions as the rectangular clear glass openings in the regular or standard screens. The second plate (fig. 1), which is placed either in contact with the first-named plate or is placed in front of it with an air space between, consists of small, round, opaque dots of about the same size and number as the clear glass openings of the first-named plate, the remainder of the second plate being clear glass. These two plates are placed together in such a manner that the opaque dot will be located in the field of the translucent portion of the first plate, *e.g.*, in quincunx order (see figs. 3 and 4). The result is a screen consisting of clear glass round apertures surrounded by a field of very translucent colour the degree of translucency of which is controllable, and within that translucent field there will appear round, opaque dots.

On account of the controllability of the degree of translucency or opacity of the translucent field it is possible to obtain materially different effects dependent upon the controlled intermediate tint and without in any case affecting or modifying the clear apertures or the completely opaque dots. The resulting half-tones produced by the use of this new screen have the same texture as those made from the regular cross-line screens, the only difference being the perfect rendering of the tonal values. The use of the new screen involves no expert manipulations or special treatments, but the tonal values will almost automatically result from the fact that the clear glass spaces, being of the proper size and number, will permit the direct passage of light in so far as the same is desired, while the opaque dots prevent the passage of light to the extent desired, whereas the intermediate translucent part of the screen will, according to the intensity of the light or the length of exposure, cause just the right light values to be imparted to the sensitized surface in connection with which the screen is used.

PITTSBURG SALON OF PHOTOGRAPHY.—The tenth annual exhibition of the Pittsburg Salon of Photography, under the auspices of the Photographic Section of the American Academy of Science and Art, will be held in the galleries of the Carnegie Institute, Pittsburg, U.S.A., from March 2 to 31, 1923. Accepted pictures from abroad will be mounted by the committee, and all pictures will be hung unframed, under glass. The last day for entries is February 5, 1923. Particulars and entry forms may be obtained from Chas. K. Archer, 1412, Carnegie Building, Pittsburg, Pa.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Prince's Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 21.—Rotherham Photographic Society. Latest date for entries October 4. Hon. Secretary, S. G. Liversidge, Orissa, Gerard Road, Rotherham.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

1923.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 14 to 19:—

APPARATUS.—No. 22,632. Aparatus for use in treating with liquids, photographic papers, films or plates. P. Bamichas.

EXPOSURE METERS.—No. 22,190. Photographic exposure meters. C. Z. Case.

FINDER AND LEVEL.—No. 22,348. Combined finder and level for photographic hand cameras. Challenge Manufacturing Co., Ltd., and J. W. Listrum.

APPARATUS.—No. 22,559. Photographing, developing, etc., apparatus. J. Hazell.

WASHER.—No. 22,580. Apparatus for washing photographic prints, plates, etc. A. W. Judge.

FILMS.—No. 22,388. Photographic films. H. L. Lucoque, E. A. E. Pilgrim, and L. C. Rudkin.

DEVELOPERS.—No. 22,389. Photographic developing solutions. H. L. Lucoque, E. A. E. Pilgrim, and L. C. Rudkin.

POSITIVES DIRECT.—No. 22,390. Production of direct photographic positives. H. L. Lucoque, E. A. E. Pilgrim, and L. C. Rudkin.

SOUND PHOTOGRAPHS.—No. 22,062. Photographic sound recording. H. G. Matthews and R. H. Ruddock.

CINEMATOGRAPHY.—No. 22,199. Cinematographic apparatus. J. S. Pocovi.

CINEMATOGRAPHY.—No. 22,418. Cinematograph and optical projection apparatus. J. E. Thornton.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 1/- each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

The date in brackets is that of application in this country; or abroad, in the case of patents granted under the International Convention.

ONE-EXPOSURE THREE-COLOUR CAMERAS.—No. 148,789. (July 10, 1920). The invention consists of a three-colour camera (which can also be used as a viewing instrument) producing three similar images on a single sensitive plate. There is an optical diaphragm, having an aperture common to three lenses and

corresponding in size to the normal opening of each lens. Two double-reflection prisms are fixed against the inner side of the diaphragm, one on each side of the axis of the latter, so that each prism covers part of the diaphragm aperture and leaves a space between the opposite edges of the prisms. The prisms can be adjusted relatively to the diaphragm aperture so that the part of this aperture which is covered by each may be regulated. The thickness of the glass plates between which the colour filter-films are mounted is so determined that the three images are in focus on the same plate.—Charles Emile Bredon, 44, Rue de Cambrai, Paris.

(Particulars of the construction of the apparatus are given on another page in the "Colour Photography" Supplement.)

Multicolour Screens.—No. 163,311 (May 12, 1921). This invention relates to a method of producing multicolour screens for use in photography, and its object is to avoid a decrease in brilliancy and clearness usually encountered in mordanting the dyes of a multicolour screen.

When an aqueous solution of tannic acid is mixed with an aqueous solution of a basic dye, these agents will precipitate each other. If, however, the water, as solvent, is partially substituted by alcohol, say methyl or ethyl alcohol, no precipitation will take place. Further, when a solution of tungstic acid, molybdic acid or phospho-tungstic acid is mixed with a solution of a basic dye, a precipitation will take place, but if the liquids are rendered basic, such as by the addition of a small quantity of ammonia, the mixing of the solutions will result in a limpid, coloured liquid without any precipitation.

According to the present invention, such limpid coloured liquids containing both a dye and a mordant, but in a form in which the agents do not precipitate each other, is now comminuted in any well-known manner, preferably by emulsifying. When the particles have been caused to adhere to the underlayer, they are dried. It is found that the dyes in the coloured tannin particles have been mordanted without precipitation. When certain other particles are used, such as coloured basic particles of tungstic acid, the mordanting is effected by a subsequent treatment, such as by an acid either in solution or in the form of vapour. If desired, the colour screen thus produced may be varnished, and then it is ready for use. Besides the dye or dyes and the mordant or mordants the particles also may contain inert substances, such as gum arabic, dextrin, albumin, etc.

In order to cause the particles produced by emulsifying coloured liquids with a suitable material, such as dammar varnish, to adhere to the underlayer, it is customary to furnish the underlayer with a cover or coating of basic character, such as gelatine with an admixture of borax, sodium silicate or the like. The particles which by the emulsification have been covered with a varnish substance showing an acid reaction will adhere to such an alkaline reacting underlayer. According to the invention, which has for one of its objects to provide a colour screen which is resistant against water and aqueous solutions, this alkaline coating is preferably substituted by another coating, which, as well as the particles themselves, is resistant against water. This purpose is attained by substituting for the gelatine coating or the like a coating consisting of or containing a basic cellulose derivative, which may be produced by applying to the surface to be coated collodion in which a small quantity of a soap, say sodium oleate, is dissolved. No claim is made to the provision of an underlayer having a coating of a cellulose derivative, as broadly new in itself, but the use of such coating with an addition of a basic substance as described.—Jens Herman Christensen, Sollerod, Holte, Denmark.

Trade Names and Marks.

APPLICATIONS FOR REGISTRATION.

Phodeko.—No. 425,944. Photographic chemicals and plates and sensitised films for photography. Cavendish's, Ltd., 87, Moorgate Street, London, E.C.2, manufacturers. May 9, 1922.

Phodeko.—No. 425,945. Photographic apparatus included in class 8. Cavendish's, Ltd., 87, Moorgate Street, London, E.C.2, manufacturers. May 9, 1922.

Phodeko.—No. 425,946. Photographs and photographic papers. Cavendish's, Ltd., 87, Moorgate Street, London, E.C.2, manufacturers. May 9, 1922.

Reprograph.—No. 427,133. Photographic apparatus included in class 8. Carl Janzer, 37, Hohenheimerstrasse, Stuttgart, Germany, engineer. June 16, 1922.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Monday, September 4.

Southampton C.C. "Table Top" Photography. J. W. Blay.

Tuesday, September 5.

Bournemouth Camera Club. Outing to Bourne Valley.
Hackney Phot. Soc. By River, Lake and Sea. Albert Hester.
Manchester Amateur Phot. Soc. Exhibition of the Originals of "Photograms of the Year."

Wednesday, September 6.

Rochdale Amateur P.S. "Carbro" Demonstration. E. Morley.

Thursday, September 7.

Royal Photographic Society. Methods of Enlarging. A. C. Banfield, F.R.P.S.

Saturday, September 9.

City of London and Cripplegate Phot. Soc. Outing to Mitcham.
Edinburgh Phot. Soc. Outing to Dalmahoy.
Hammersmith Hampshire House Phot. Soc. Outing to Hayes Common.
Sheffield Phot. Soc. Outing to Dronfield and Barlow Lees.
Southampton C.C. Outing: Around Southampton Docks.
Willesden Phot. Soc. Outing to Kensington Gardens.

CROYDON CAMERA CLUB.

At last Wednesday's meeting Mr. F. Ackroyd gave the concluding part of an informal and highly interesting chat on a tour abroad which included the Passion play at Oberammergau, Mr. J. C. B. Coffin following with an instructive lecture on "Vickers' Duralumin," the aluminium alloy.

Whilst being about the same weight as aluminium, Duralumin differs from it in several important respects. It has a far finer appearance, and takes an excellent dull, white, and polished finish. It can be machined and tapped like brass, does not rust, nor readily tarnish, even under adverse conditions, and last and by no means least, it has a strength of mild steel. When heated to a definite temperature Duralumin temporarily softens, regaining its original hardness in the course of a few days. This makes the production of difficult pressings possible, which afterwards regain full strength, quite a unique feature.

The strength of aluminium, he said, compares very unfavourably, and in order to obtain sufficient strength for the object in view so much metal has often to be employed as to save little or nothing in weight. He was surprised Duralumin was not more largely used in camera construction, having regard to the modern pronounced tendency towards lightness and portability, and the ease with which the alloy met these requirements combined with elegance and rigidity.

A Newman and Guardia folding reflex camera largely made of Duralumin was then passed round—a splendidly designed and constructed instrument which was examined with much interest by many covetous eyes. Certainly it costs good money, but Mr. Harpur, after close scrutiny, declared the camera to be dirt cheap at the price. A very ingenious and rigid "walking-stick" "N. and G." tripod made of the same metal also attracted much attention, as did the Duralumin skeleton frame and gear wheels of Messrs. Sinclair and Newman's well-known cinematograph camera. Photo frames, shutter cases, horseshoes as worn by Derby winners, and many other pressings and fitments were also shown.

In the discussion, Mr. Vivian Jobling said he could confirm the lecturer's high opinion of Duralumin. By substituting it for brass in hand cameras the selling value would be increased at but slight additional expense.

Commercial & Legal Intelligence.

LEGAL NOTES.—Notice is given of the dissolution, by mutual consent, of the partnership between Charles Henry Holmes and Herbert Holmes, carrying on business as wholesale photographic dealers at 41, Oxford Street, Manchester, under the style of Holmes Brothers. All debts due to and owing by the late firm will be received and paid by William Eaves, incorporated accountant, 15, Fountain Street, Manchester.

NOTICE is also given of the dissolution, by mutual consent, of the partnership between John Carter Collins, "Hazelrigg," 6, Hawthorn Gardens, Gateshead, Durham, and Willam James Moore, 17, Elliott Terrace, Newcastle-on-Tyne, carrying on business as photographers at 30, Green Street, South Shields, under the style of Collins & Moore. All debts due to and owing by the late firm will be received and paid by John Carter Collins, who will continue to carry on the business under the style of J. C. Collins.

NOTICE is given, pursuant to Section 242 (3) of the Companies (Consolidation) Act, 1908, that at the expiration of three months from August 25 the name of the Westbourne Studios, Ltd., will, unless cause is shown to the contrary, be struck off the Register of Joint Stock Companies, and the company will be dissolved

AT BANKRUPTCY BUILDINGS, Carey Street, W.C., on Wednesday, the adjourned general meeting of the creditors was held of John Robert Jeffs Pearson (trading as Albert Flint & Co.), photographer, described in the receiving order as of 68, Church Street, Camberwell, S.E., and residing at 1, West Avenue, Walthamstow, Essex, against whom a receiving order was made on December 18, 1911. This debtor has submitted a proposed scheme of arrangement under which all his creditors, with the exception of John Jeffs Pearson and Mary Jane Pearson, will receive a sum in cash, which with the dividend declared and already paid, will amount to 20s. in the £. The proposal provides for the release of the claims of John Jeffs Pearson and Mary Jane Pearson, which aggregate £417 10s. The scheme was agreed to by the requisite majority in number and value of the creditors' claims.

NEW COMPANIES.

PICTURESCOPE, LTD.—This private company was registered on August 14, with a capital of £1,000 in £1 shares. Objects: To carry on the business of inventors, designers, chemists, investigators, patentees, licensees, licensors or concessionaires, and to develop or exploit any invention or discovery connected with the graphic arts, printing, photogravure, collotype photography, kinematography, photographic and mechanical colour printing, sensitive photographic materials, optics, etc. The first directors are: J. E. Thornton, 14, Minster Road, W. Hampstead, N.W., manufacturer; W. L. Bayley, Morland Close, N.W.11, advertising agent. Qualification: £1. Secretary: J. N. Thornton. Registered office 4-10, Chenies Street, W.C.

PRINCESS YVONNE, NEWCASTLE, LTD.—This private company was registered on August 10, with a capital of £200 in £1 shares. Objects: To acquire the business of photographers carried on by Whinfield, Ltd., at 161, Northumberland Street, Newcastle-on-Tyne, and to enter into an agreement between T. Hall, of 37, Groat Market, Newcastle-on-Tyne, and Edith Plummer, photographer, of 24, Albion Place, Leeds. The subscribers (each with one share) are: Edith Osborne, 103, Whetstone Lane, Birkenhead, photographer; Edith Whitehead, 132, Falkner Street, Grove Street, Liverpool, photographer. Mrs. Edith Plummer, of 103, Bedford Street, South Liverpool, is the sole director for life. Secretary: Edith Osborne. Registered office: 161, Northumberland Street, Newcastle-on-Tyne.

DEFEATING THE PRESS PHOTOGRAPHER.—The "Daily Chronicle" tells the following story:—Having fought and overpowered a burglar who had invaded her home, a Daventry woman made short work of a Press photographer. Her feat brought her a visit from a Press representative, who asked permission to photograph her. The lady refused, and as the persistent photographer prepared to level his camera to take a picture of her house she produced a double-barrelled gun, and, levelling it at the camera man, threatened to shoot him unless he departed. Deeming discretion the better part of valour, the photographer postponed the taking of the picture to a more auspicious occasion.

News and Notes.

MESSRS. WELLINGTON & WARD, LTD., have sent us a novel form of advertisement. It consists of a letter asking four questions, and accompanying the letter is an attractive postcard for replies to the questions.

AERONAUTICAL PHOTOGRAPHS FROM THE GROUND.—The September issue of the "Scientific American" contains an article describing how aeronautical photographs may be taken from the ground. A triple gyroscopic balanced camera operated by electricity is used, the camera being carried to any desired elevation by a small pilot balloon. The camera takes twelve plates, and excellent results have been obtained at 3,000 feet.

PHOTOGRAPHS FOR THE GLASGOW EXHIBITION.—Schedules and entry forms are now ready for the photographic competitions arranged in connection with the Housing and Health Exhibition, promoted by the Corporation of Glasgow, to be held in the Kelvin Hall, Glasgow, during the three weeks commencing October 2 next. A sum of £150, along with a valuable challenge trophy, will be awarded in prizes. Special arrangements have been made for the display of all the competitive photographs under glass, thus affording them full protection during the period the Exhibition will run. There are three classes—open, beginners, and juveniles, and the judges are to be Mr. Archibald Cochrane, Mr. James McKissack, and Mr. F. J. Mortimer. Entries close on September 15, and the judging will take place on the 21st inst. Schedules and entry forms will be sent on application to Mr. C. P. Hainsworth, Kelvin Hall, Glasgow.

P.P.A. CONGRESS NOTE.—In addition to the items arranged in the preliminary programme of the P.P.A. Congress: Mr. Lang Sims, has arranged for a visit to the half-tone and colour illustrating departments of the Amalgamated Press, Ltd., by the kind invitation of General W. F. Mildren, C.B., C.M.G., D.S.O. Mr. Lang Sims will meet the members on the Surrey side of Blackfriars Bridge at 10.30 a.m., on Wednesday (September 13), and conduct them to the works. Tickets must be obtained from Mr. Alfred Ellis at the Princes Galleries, W.1. In order to facilitate the distribution of badges, tickets, etc., for the Congress members are requested to send their list of requirements (together with the amount) on the form supplied for this purpose to Mr. Alfred Ellis, 2, Vinery Villas, Hanover Gate, London, N.W.8, who will place them in an envelope ready for members on their arrival at the Princes Galleries during "Congress Week."

HISTORIC OPTICAL AND CINEMATOGRAPHIC APPARATUS AT SOUTH KENSINGTON.—On Saturday last there was opened in the scientific section of the South Kensington Museum an exhibition devoted to the history of the moving picture. This exhibition has been got together by Mr. Will Day (who has been collecting for more than twenty years), and contains more than 500 separate exhibits. It occupies nearly the whole of the Science Annexe, and is so arranged that it is possible easily to obtain a chronological survey of the industry. The cases are each named according to their contents. The first case of exhibits, for instance, is described as "Persistence of Vision," and contains the results of early experiments in this direction; the next is called "First Forms of Moving Pictures," and others "First Book Forms" and "First Lantern Forms." Eventually we arrive at the most elaborate and up-to-date projecting instruments. One of the exhibits is a book containing a picture of the magic lantern which Kircher invented in 1640, while another explains Dr. Roget's discovery of the persistence of vision on which the theory of the cinematograph is based. In the same case is Sir John Herschell's "thaumatrope," which was discovered nearly one hundred years ago. From these, through the "phenakistoscope" and the "stroboscope," developed the "zoetrope," which was patented by Desvignes in 1860. Other inventions followed, until finally in 1885 there was born the cinematograph as we know it—invented by Mr. W. Friese Green. A case is devoted to the work of Mr. Friese Green, and in it is a copy of his provisional specification for the invention, in which it is referred to as "a method of taking photographs in rapid series." The first commercial cinematograph is also shown—that perfected by Mr. R. W. Paul—which was used at the Alhambra in March, 1896. There are also the original lantern slides of the Coronation procession of George IV., a most interesting exhibition to which admission is free.

A PHOTOGRAPHIC PROBLEM.

To the Editors.

Gentlemen,—May I place on record the peculiar result of an experiment which, for reasons that need not detain us, I was led to make a short time ago.

A slow "Ordinary" plate was laid on the darkroom bench with a penny on top of it, and given an exposure of about 1,000 C.M.S. It was then placed in a 0.2 per cent. solution of methylene blue B, and rocked for six hours, after which is was washed in running water for two days, all operations being conducted in *total* darkness. On bringing it into the light, a disc of undyed emulsion was visible where the metal had protected it from exposure.

The experiment was repeated, using other plates, namely, Royal Standard Lightning, Wellington Extra Speedy Press, Iso Speedy, and S.C.P. Lantern, Imperial Process and Lantern, but without effect. Rhodamone *B* and magenta 1a were without effect. Only methylene blue B and Wratten Ordinary plates gave any noticeable result.

The matter seems worthy of investigation, as it suggests a new field for development processes.

Perhaps you or your readers can relate a similar experience, or offer an explanation.—Yours faithfully,

KENNETH HICKMAN.

Imperial College of Science and Technology,
South Kensington, S.W.7.

PHOTOGRAPHS FOR BLOCK-MAKING.

To the Editors.

Gentlemen,—Your contributor D. Charles, in his article in last week's "B.J." on "Avoidance of Reflection Markings," says: "Blockmakers naturally encourage the employment of their 'art' departments, and so the worse the photographs supplied the more profit they make." Like most cynical remarks, I believe this aspersion to be untrue. I know the block-making business, and will assure him that more profit is made out of good copy than ever will be made out of bad. It is indeed obvious that when an artist has to guess what the details of an article are on a bad photograph he often guesses wrong; result, dissatisfaction and alterations demanding more costly time which, even if paid for at all, you may depend it will not be at a profitable rate.

One block-maker tells me he has spent over £100 in experiments in photographic polished goods free of reflection markings, and claims success for his perfected method. I wonder why he took the trouble if he could make more profit by photographing badly so as to keep his artist department busy?

The more Mr. Charles can teach us about taking good photographs for block-making the more pleased, I can assure him, block-makers will be.—Yours faithfully,

E. H. A

SYSTEM IN HALF-TONE OPERATING.

To the Editors.

Gentlemen,—In reply to Mr. Biermann's letter in the "B.J." of July 7, I can only hope that he will refer back to the article and satisfy himself that the discussion therein has been restricted throughout to pinhole conditions below, and up to, the normal distance. Mr. Biermann agrees that the diagram illustrating the passage "suggests that it is so." I should like to add that not only that particular diagram or passage, but the entire contents of the article, including the diagrams, would similarly "suggest" that the analysis does not extend to distances beyond the normal. If after this, and in spite of the footnote excepting in clear language all "cases where the screen distance is greater than the normal distance, for the stop used," Mr. Biermann continues to hold that "there is not a word about the screen distance being below the normal," I can only express my inability to see the point of his contention. Surely the author's reference to "the great majority of cases" in this connection can have no meaning at all unless it refers to cases within the scope of his discussion?

I shall not do Mr. Biermann the injustice of taking his statement that he "cannot find anything in practice that agrees with the geometrical projection" "in a strictly literal sense." Mr. Biermann must have his reasons for considering the screen distances suggested in the article as being "always too great," but in the absence of any definite data regarding his "missing factor" it may be allowed to stand where it is. My own experience of the ordinary cross-line screen has been limited to a much smaller range of screen rulings—for the finest screen that I have handled (175 lines) is of the 60 deg. type, and for coarse-grain work we invariably prefer to use a four-line screen. But within this limited range my experience definitely contradicts that of Mr. Biermann. Such divergence of experience can only be reconciled by a systematic comparison of notes.

As Mr. Biermann is "obviously anxious" to be fair, I ought to point out that this article is one of the very earliest of my father's writings on the subject, and it represents the beginnings rather than the conclusions of his researches. They are largely based on visual microscopic observations with comparatively coarse screens, an 85 line screen being, I believe, used for most of his earlier experiments. The opportunities for adequate observation on a commercial scale were at that time practically absent, for my father was a pioneer worker here in this field, and the printer's prejudice against the half tone block was almost overwhelming at that stage. These early articles may, therefore, appear to be incomplete, but they are perfectly consistent and logical, so far as they go. His teachings, I need not add, have been greatly amplified in his subsequent writings, which represent his maturer views and ideas on the subject.

My sole object in joining this correspondence was to suggest that the discussion be confined within definite and constructive limits. No one with any real knowledge of the conditions of half-tone work can be an exclusive advocate of this or that particular theory. If we try to trace out the light rays, travelling along their appointed straight paths from diaphragm to image plane, we get the inevitable pinhole image, and that phenomenon must be there, however much it may be masked by the superposition of other optical effects. It is, of course, well known that under certain conditions light rays do actually extend beyond their straight paths and interfere with each other. As such conditions are always present to some extent in half-tone practice, we are bound to find diffraction effects more or less in evidence. The same remarks would apply to the case of irradiation. I submit, however, that for our present purpose it is neither necessary nor desirable to go into the alleged claims of the rival theories until sufficient tangible data are available to make such discussions fruitful and profitable.

Looking beyond my own experience, I have noted some striking differences in the ideas and practices of half-tone workers in England as well as elsewhere. There are operators whose main concern seems to be the reduction of exposures, and they habitually use the largest permissible stops and correspondingly short screen distances, while others (mostly dry-plate workers) claim special advantages for small stops and long distances. Personally I hold that such different methods would show material differences in tone rendering at both ends of the scale. Then there are variations in the types of negative aimed at by different workers. Some dry-plate workers (and I am one of them) do not, as a rule, attempt to imitate the usual wet plate type of negatives, but deliberately prefer, in most cases, to have fairly substantial dots in the shadows, which are closed up during the printing on metal. The degree and character of the "opening up" which controls the size and shape of the high-light dots also present wide scope for variations. Again workers who are generous in their use of the square stop placed "diamond" fashion apparently obtain a certain vigour in the lower middle tones, which are unattainable by those who go to the other extreme of using elliptical and similar stops with openings extended in the direction of joining up.

We require definite quantitative information regarding the variations in tonal rendering given by such differences in practice. The only published work along such lines of which I am aware is that of Messrs. Bull, Smith and Turner, whose researches, I earnestly hope, are still being continued. I feel that fruitful research work would be greatly stimulated if workers who have adopted systematic methods of work would publish definite informations regarding their ex-

perience. Mr. Biermann has given us a concrete instance of this in detailing his relative standards of procedure in the cases of 50-line and 200-line screens. I am convinced that, even on this point, other workers, working along different lines, with different sensitive surfaces, and aiming perhaps at different types of negatives, will have significantly different experiences to relate.—Yours faithfully,

SUKUMAR RAY, B.Sc.

Calcutta, August 3, 1922.

Answers to Correspondents.

In accordance with our present practice a relatively small space is allotted in each issue to replies to correspondents.

We will answer by post if stamped and addressed envelope is enclosed for reply; 5-cent International Coupon, from readers abroad.

Queries to be answered in the Friday's "Journal" must reach us not later than Tuesday (posted Monday), and should be addressed to the Editors.

C. C.—The makers of the Sanderson camera are Messrs. Houghtons, Ltd., 88-89, Holborn, London, W.C.1.

B. T. H.—A reflex camera is very suitable for home portraiture, and an *f*/4.5 lens is almost indispensable. Practically all the cameras on the market are good value for their respective prices, and the make you mention is quite reliable if it is in good condition.

T. C.—You can try what a weak solution of ammonium sulphocyanide will do to take out the stains, a cause of which very often is the use of the hypo-ferricyanide reducer on a print which has not been completely washed from a fairly strong hypo-fixing bath.

L. R. S.—We do not know of such a lens. The effect you describe is usually obtained by tilting the copy considerably, and using an ordinary lens greatly stopped down for the sake of depth. In this way you can distort a flat original in one or other of its two dimensions.

R. G.—Many workers advise a good washleather for ridding the surface of a negative from superfluous moisture before putting it to dry. The washleather will mop up the maximum of moisture without leaving any particles on the gelatine surface. The leather should be one without stitches in it, and should be washed out in warm water, with a little washing soda dissolved in it before taking into use.

H. B. E.—In your particular case it is quite out of the question to use a 5-inch lens upon a half-plate reflex camera, as even if the lens could be sunk sufficiently, the mirror could not work. Few cameras of this size will work with less than an 8-inch lens, and many require a still longer focus. In any case, even with an ordinary camera, 5 inches is far too short a focal length for anything but wide-angle work

J. E. W.—We do not think that you will need any additional lamp for heads if you make the two following alterations:—Have your lamps made to lower so that they can be brought down to, say, 5 ft. 6 ins. for sitting figures. This will greatly shorten the exposure. Also bring the sitter nearer the light. This will give more vigour in the lighting. Substitute fine nainsook for the Japanese silk, which is far too thin; this will get rid of the four shadows.

S. R. G.—We cannot say. Some time ago Dr. C. E. K. Mees stated that measurements showed that, during the first eight or ten hours after exposure, a plate or film shows an increase in speed of about 15 per cent., the speed then remaining constant within the accuracy of measurement. The increase is rapid at first, the speed increasing about 10 per cent. in the first four hours. There is little change in the contrast, the change being entirely a shift of the inertia point of the curve.

F. J. C.—Postcards or prints, generally of the sketchy type, on double weight paper are best flattened by putting through the hot dry-mounting press, but the secret of making them remain flat is to first press face up (assuming the press is heated from above), then to remove from the press and at once lay face down on the still hot zinc plate. The print instantly begins to curl the reverse way, *i.e.*, the face becomes the convex side. If removed as soon as this tendency becomes evident, it will remain indefinitely in that flat condition. With a good size press, several prints can be done at once, and it takes less time than the ordinary dry-mounting.

C. P.—A formula for an acid fixing bath containing metabisulphite is :—

Hypo	4 ozs.	100 gms.
Potassium metabisulphite ...	200 grs.	13 gms.
Water to	20 ozs.	500 c.c.

A formula for a combined fixing and hardening bath is :—

Hypo	4 ozs.	200 gms.
Potassium metabisulphite ...	60 grs.	6.5 gms.
Chrome alum	240 grs.	25 gms.
Water to	20 ozs.	1 litre.

The hypo and metabisulphite should be dissolved in one-half of the water and the alum in the other. The two solutions should then be mixed.

C. P.—(1) The formula for the lead intensifier in the form you require it is :—

Lead nitrate	400 grs.
Potass. ferricyanide	600 grs.
Acetic acid	3 drachms.
Water to	20 ozs.

This stock solution will keep for a long time in the dark. The negative is bleached in it, washed once very carefully in 10 per cent. nitric acid—the acid makes the film very tender—then in water, and then darkened in :—.

A.—Sodium sulphide	1 oz.
Water	20 ozs.

(2) The plates work flat as the age increases.

S. H.—(1) We think for very dense negatives that the enclosed arc is to be preferred. This should be of the right-angled pattern, as in the small Westminster projection lamp. The great trouble of uneven burning is practically obviated by this model. With the vertical carbons the arc has a tendency to dodge round from front to back, so that two consecutive exposures may vary to the extent of 50 per cent. (2) It is impossible to give any limit, we sometimes use a 3-inch lens, with a 10½-inch condenser. For general work a 9-inch objective works well with an 8½-inch condenser, and if the half-plate is to be covered we should not care to use less than a 7-inch. (3) With a small source of light a ground-glass screen is almost essential. Not only does such a light show up scratches, retouching, etc., but there are few condensers of high enough quality to give an even disc with the naked light.

JOURNAL OF PHOTOGRAPHY.

No. 3253. Vol. LXIX. FRIDAY, SEPTEMBER 8, 1922. Price Fourpence.

Contents.

SUMMARY.

The Congress, which celebrates the coming of age of the Professional Photographers' Association, opens on Monday next at Princes Galleries, Piccadilly, London, W. (P. 529.)

A very full week of lectures, demonstrations, visits, and discussions has been arranged. The full programme of fixtures will be found on page 537.

At the annual general meeting of the P.P.A., to be held on Friday next, September 15, the report of the Council (p. 537) will be proposed, and the opportunity given for discussion of the work and policy of the Association.

In the present number of his series of articles on studio portraiture, Mr. J. Effel deals in a conversational style with the three-quarter length portrait. (P. 532.)

The quiet season, which is experienced at one time or another of the year in almost every business, may appropriately be the occasion for overhaul both in the commercial and technical department. (P. 530.)

In some notes on the D. & P. trade, "Thermit" expresses the opinion that businesses which are experiencing depression require to look more towards improvement or variation of the work which is supplied rather than to reduction in prices. (P. 536.)

In a contributed article, Mr. A. H. Hall gives his experience in the use of the Pinakryptol Green desensitiser in comparison with phenosafranine as regards the occurrence of stain and the use of the process for film. (P. 531.)

A further chapter of the series on depth of focus describes the ingenious optical conception of Dr. M. von Rohr, namely, the "plane focussed for," by means of which formulæ for depth of focus are rendered very much more simple, since they are based entirely on distances in the object space without reference to the focal length of the lens. (P. 534.)

The R.P.S. exhibition is to be opened, on September 16, by Mr. Solomon J. Solomon, R.A. (P. 542.)

A recent patent describes a focal-plane camera in which the picture is focussed up to almost the instant of exposure on the white blind of the focal-plane shutter. (P. 538.)

Occasional examples of fading of sepia-toned postcards are to be met with. (P. 529.)

Lantern slides from hard under-exposed negatives are often improved by use of one or other of the bleaching processes of toning. (P. 530.)

Further developments in the dye-toning of silver images have been patented by Mr. W. van Doren Kelley. (P. 539.)

For making a number of exposures on a single plate a mask of thin wood or stout card can be readily extemporised. (P. 530.)

EX CATHEDRA.

The Eve of the Congress. The diary of fixtures which appears on another page of this issue is a final reminder of the very great number of attractions which the Council of the Professional Photographers' Association has provided for the "coming-of-age" congress which opens on Monday next, September 11. It will be a crowded and strenuous week. From the hour of the official opening of the Congress Exhibition at noon on Monday to the advance private visit on the Saturday to the R.P.S. Exhibition, members of the P.P.A. will have little opportunity to rest, or go about other business, if they avail themselves of the full programme of lectures, discussions, demonstrations, and excursions which the Council has provided with a lavish hand. In the names of those who will lecture and will preside at the meetings they have the assurance beforehand that this year's Congress is an event in the history of the Association worthy of the occasion which it celebrates, and one in which every member will take part, whatever the sacrifice of time or business which may be required. It is not too much to say that the Congress represents a gathering of the forces in professional photography such as has never before been witnessed in England. Where all is of such technical or professional interest it is hardly fitting to lay emphasis on special items of the programme, but attention may be drawn to the inspiring presence at the Congress of Mr. Pirie Macdonald and of Mr. Aylett of Toronto, who will lecture on "Unusual Portraiture." The questions of fraternity among photographers of the relation of assistants to the P.P.A., and of the co-operative advertising of portrait photography are also subjects of pressing interest to photographers, from the discussion of which much good should come. We need say no more, except to congratulate the organisers of the Congress on the great work they have done and to wish all the members a profitable and enjoyable visit.

* * *

Faded Bromide Prints. Since the introduction of sulphide toning, an idea has become prevalent that, as sulphide of silver is a fairly stable compound, therefore toned bromides may be regarded as practically permanent. Although they are less liable to change than untoned prints, they cannot be regarded as invariably quite permanent. We have noticed a decided weakening in very carefully made prints after a year or two, and recently in inspecting a frame of sepia postcards the other day we saw several which, owing to condensation upon the covering glass, had faded in patches from a rich warm sepia to a sickly yellow. It may, of course, have been the case that other chemicals than those of the customary bleach and sulphide had been used. As far as our experience goes, prints toned in hypo-alum to a purplish brown or P.O.P. colour appear to be more

permanent than those toned to a warm brown. Some papers will not tone to a real sepia in a single bath. It would be an interesting and profitable field for experiment if the subject of sepia toning were investigated in respect to the permanence of the results.

* *

Toned Lantern Slides from Hard Negatives. Beginners with a hand-camera who may be dissatisfied with their first essays in lantern-slide making on account of the hardness of the transparencies from the often under-exposed negatives, may be well advised to make the use of the little known process of bleaching the slide. The process softens the gradation and at the same time produces an agreeable colour. One of the readiest bleaching solutions is made by dissolving 10 or 20 grs. of mercury bichloride in an ounce of water, but if this is objected to on account of its intensely poisonous properties, an alternative is one of potass bichromate, 10 grs., and hydrochloric acid, 5 drops, in the same quantity of water. The bleached slide is transferred to a weak bath of potass metabisulphite to remove the yellow stain, washed briefly, dried and exposed to daylight for a day or so, by which a warm brown tone is produced. By using 5 grs. of potass bromide and 5 drops of nitric acid in the above formula, instead of hydrochloric acid, a similar result is obtained, but of cool grey tone, whilst iodide in place of bromide in the modified formula yields a pleasant brown.

* * *

Multiple Exposures. It sometimes happens that a number of small negatives are required for passport or season ticket portraits or for small prints for advertising purposes. In such cases, to use even a quarter-plate for each is wasteful, not only of material but of labour, as every exposure has to be handled separately, both in development and printing. With very little trouble it is easy to make four exposures upon a half-plate in any studio camera provided with a repeating back. All that has to be done is to make a mask of thin wood or stout card to fit into the ordinary cabinet mask, having an opening the size of the desired exposure, placed centrally as regards width, but extending from one edge to the centre for length. Fresh marks must be made upon the dark slide, so that the plate will be accurately centred for each exposure. After two exposures have been made the mask is reversed and the second pair exposed. It is, of course, quite easy to extend this system to eight upon the half-plate with only one reversal of the mask. In order to avoid confusion with the existing notches for cabinets and cartes, it is a good plan to put the fresh markings on the lower runner of the repeating back, with a small non-projecting pointer on the frame of the slide.

* * *

Improvised Plate Carriers. It is sometimes convenient to be able to adapt without much labour smaller sizes of plates in ordinary dark slides in the absence of properly-made frames. The photographer who has a little mechanical skill in the use of tools can easily do this, using either wood or metal, but as a rule a good deal of time is needed, and on a journey the materials are not always to hand. For small sizes, say, 5 x 4 to half-plate or ¼ to 9 x 12 c.m., very good carriers may be made from stout card, the thickness chosen being nearly equal to that of the plate. This can usually be procured in the form of boxes from a draper or grocer. If the width of margin permits, the carrier may be made by cutting the outside of the card to fit the slide, with an opening the size of the plate. Across the corners pieces of wire are fixed for the plate to rest upon; hairpins answering excellently. If the card be white no apprehension need be felt; there is no more danger of reflection than if the full-sized plate were used. Another dodge is to cut out the opening and to insert the plate face down, then sticking one or more gummed luggage labels all over the frame and back of plate. This will answer with metal slides.

THE OFF-SEASON.

The photographer who has no dull time during the year might be thought to be in an enviable position, but whether this is so can only be proved by referring to his bank balance, for a man may work hard every day in the year and make little money, or he may have a short, busy season and make much. Anyway, most photographers do have a quiet time once or twice a year, and besides taking a holiday, which is usually well earned, the question is how to make the best use of the quiet time. In the first place, naturally, will come all arrears of routine work, if any exist, such as filing away negatives, overhauling stock, and generally turning out dark- and work-rooms. Next comes the question of repairs and renovations of apparatus and plant. In too many studios it is the custom to wait until a breakdown occurs before any notice is taken of the condition of the plant. This often happens at a time of pressure, when loss of time means loss of money or of prestige. An actual happening will illustrate this point. A sudden failure of a dry-mounting press revealed the fact that an essential part was worn out. It was found impracticable to procure a duplicate part from the makers, and an engineer took several days to make one to order. Meanwhile, there were two alternatives, to buy a new press or to send all prints to a trade house to be mounted. The expense of either of these courses could have been obviated if the defect had been remedied during a slack time. It is hardly necessary to mention the necessity for similar attention to studio apparatus, which certainly wants tuning up at least once a year.

Not only the technical, but the business side should be thoroughly overhauled. Every effort should be made to collect outstanding debts. In a well-managed business these should be few in number, but at any rate their amount is better placed in the passbook than in the ledger. If any new departure in book-keeping is to be made, such as the substitution of a card index system for the old books, now is a favourable time to prepare for the change, so that nothing will have to be done at the beginning of the new financial year.

Advertising schemes should receive attention, as there is no business too small not to benefit by advertising, while none is too large to be able to do without it. Folders should be drafted, circular letters composed, and prints and enlargements made and finished, not only for one display, but to allow of frequent change. If there are several employees on the staff, it is better to keep them busy in this way than to reduce their number in the slack season and to trust to picking up what help may be available when things begin to move. A contented staff, with a feeling of security of tenure, is one of the finest assets a business can possess, as they will usually be willing to work at high pressure when needed, if they know that a few weeks of slow business do not mean dismissal.

There is an old adage which says, "Never swop horses when you are crossing a stream." In other words, choose a suitable opportunity for making any important change. If a new departure of any sort is to be made, if

it be thought, for instance, that soft-focus work might be introduced with advantage, work the matter out carefully in the quiet time, and get a good range of specimens ready, instead of trying to squeeze it in at a rush time. Even a change of plates or paper is better made when there is ample leisure. If certain specimens give a favourable impression, it does not follow that similar results are to be produced at the first trial before the characteristics of the material are fully understood.

It is rather curious to consider the different ways in which the average man treats his business and his motor car or motor cycle. The one which gives him bread and butter is left to run on with little or no care as to its upkeep, beyond what is actually forced upon its owner, while the car, which is in most cases only a means of spending money, is nursed and cossetted and every new gadget procured for it, most being done in bad weather when the road is not inviting. Surely the moral is to take down the engine, decarbonise the cylinders, and adjust the bearings of the business as well as of the car.

SOME EXPERIMENTS WITH DESENSITIZERS.

In a recent number the advantages of Pinacryptol Green as a desensitizer were extolled, and therefore I have thought that the results of some practical experiments might be useful.

Half a gramme of this dye was dissolved in 8 ozs. of distilled water, making a solution of 1:500 with sufficient accuracy. A further dilution to ten times the volume makes the working solution. Thus 80 ozs. of solution is available at the cost of 2s. 8d. for the dye, which, in small quantities, is more expensive therefore than phenosafranine.

To test the staining properties, the emulsions which had given most trouble with Desensitol, *i.e.*, phenosafranine, were used, and a first test was made with Wellington double-coated anti-screen plates.

Four quarter-plates from the same box were taken, and after exposure two were placed for one minute in Desensitol, and two for the same period in Pinacryptol Green. All four were given a rinse in plain water, and were developed together in a whole-plate dish with pyro-soda, "B.J." formula, without bromide. The illumination was a Wratten OO safelight, which is a very bright yellow. There was no appreciable difference in the time of development, and the plates were fixed in the normal way with a hypo fixing bath made up with potass. metabisulphite. The two plates desensitized with Pinacryptol Green were free from visible stain as soon as they were fixed; the other two were badly stained. One of these, placed immediately under a tap, so that water in some volume ran directly over it and away, took 2½ hours in such favourable conditions before the stain appeared to be removed. Swabbing with cotton wool showed that the dye had not been completely eliminated, though the plate was clear for all practical purposes. The other was placed in a 12 in. × 10 in. dish, so that water flowed in at one corner and out at the corner diagonally opposite, the flow being sufficient completely to clear the water, which was dyed for the purpose, in about ten minutes. In such circumstances eight hours were required for the discharge of the dye. Of course, by the use of a fixing bath containing acetic acid or by the use of an alum bath after fixing, the time could have been much shortened.

Repetition of these tests, using D50 as a developer, did not give any material alteration.

The other material which has given the writer some trouble with Desensitol was film, both flat films and film packs. Similar experiments were tried with a film pack. Pinacryptol Green gave no stain; the pink stain with Desensitol was most persistent, and one film, which was probably in the solution for longer than the rest, was still appreciably stained after 36 hours' washing in running water and 3 days' soaking with occasional changes. It would seem, therefore, that in the cases mentioned some procedure other than plain washing is necessary. The writer has developed many films and double-coated plates after Desensitol, and has found that, to avoid staining as far as possible, it is necessary not to exceed the time of immersion of one minute, to give the film a couple of baths of plain water for a minute each before development, and to use a fixing bath with acetic acid (the Kodak acid fixing formula is successful). If necessary, an alum bath should also be used after fixing and partial washing, and from this stage hand washing, *i.e.*, having the films in water and frequently changing, is more effective than running water in any reasonable volume. It should be noted that both methylated spirit and formaline will help to discharge the dye, but if the procedure outlined above is followed there should be no need to use them.

Both dyes will become less effective with constant use, and it is advisable to filter through cotton wool at each time of pouring back into the bottle and not to be too particular to pour back the last dregs. Also the solution should be kept up to a constant volume by the addition of fresh from the stock bottle constantly. In this way the solutions can be used with safety and economy.

Ilford and Wratten panchromatic plates developed by candle light showed no difference, the pink stain of the Desensitol being readily discharged with ordinary washing, though the plates are always twice rinsed in water before development. For some unexplained reason the earlier batches of double-coated plates desensitized with Pinacryptol Green were not so clean as those developed at the same time, and treated with Desensitol, and the skies were rather badly marked with semi-transparent spots. It is not clear that the desensitizer had anything to do with this, but actually one of a pair of plates with the connecting film unbroken when taken out of the box showed this defect in the green dye, while the other did not in Desensitol. Both plates were exposed at the same time, and were taken straight out of the Mackenzie-Wishart envelopes for simultaneous development. Latterly, however, it has not been possible to repeat this trouble, which appeared more than once.

A trial was also made with bromide paper, which had one minute's immersion in the green dye, and was then developed within 3 ft. of a medium-sized inverted incandescent gas burner with success. Normal washing removed any stain. It is not thought that this use will have much application, though it might on occasions be useful for the demonstration of development of a bromide print before a number of persons.

The writer concludes that for all ordinary purposes Pinacryptol Green is less trouble to use, but the stain of Desensitol being readily removed by ordinary washing there is no real practical advantage. For films and double-coated plates the former has great advantages. It is interesting to note that Desensitol acts as an indicator of proper fixation; the double-coated plates take a very long time to fix, and once or twice they have been removed before fixation is finished. In such circumstances no amount of washing will remove the stain where the silver is not fixed out, but this part will assume a brownish appearance. On re-fixing the characteristic pink stain re-appears, and is then readily removed by washing.

A. H. Hall.

WITH A PORTRAITIST IN THE STUDIO.

[The previous papers of the present series have dealt with the bust portrait; the point of view; spacing and sizing. In the present chapter, the author, Mr. J. Effel, returns to the making of the three-quarter length portrait in his endeavours to bring studio practice intimately before those making a study of it.]

VI.—THE THREE-QUARTER LENGTH.

A THREE-QUARTER length photograph might be described as a bust with a body, arms and legs added on, and to call for extra skill. In a way this is the case, George, for I confess that I heave a sigh of relief when I know that an awkward sitter only wants a head and shoulders picture. But it really cuts both ways, for as I said to you when we took a bust portrait, one has to concentrate on the lighting and expression more than in a picture where there is a wider interest, so with the three-quarter figure the lighting and poise of the head may be somewhat subordinated to the general effect. Indeed, with portraits of ladies, compromise with the head and dress is frequently necessary. I bring up this point at the outset of our day's lesson for I want you to get the proposition right at the start. Obviously one cannot get one side of a lady's head and another side of her dress at the same time unless our subject is a contortionist; and the same remark applies to lighting. If it were merely grafting a little more on to a head and shoulder portrait, we could just start where we left off. But although the head *is* man's chief end (and woman's too) it is not the only consideration, or necessarily the premier consideration of the three-quarter length. The nature of each composition must determine the relative importance of the head to the complete scheme, but as with full lengths, the first consideration must be the general effect.

So far, George, we have had two models, and both men. There was nothing accidental or hap-hazard in my method. Quite three-fourths of our trade is with the fair sex, and I think the proper study for photographers should be women. I have carefully thought out the continuity of my course, and am attempting to proceed from the simple to the complex. It is because I think photographing women successfully calls for every ounce of artistic knowledge to be in waiting that I am leaving a full consideration of portraits of ladies till you have assembled more general guiding principles. Still, to introduce variety into our work I have asked Miss Miller to give us a few minutes this morning. We will think of her as a sitter wishing three-quarter length portraits.

Before our smart little typist puts in an appearance, I want you, George, to reflect upon what I said recently, that you should " pose " as little as possible. How is that consistent with my constant yapping about variety and novelty, and my insistence that the composition must be harmonious in detail as in mass effect? Frequently in art circles one hears the criticism that a painter is a clever " workman," and there is a slight disparagement behind the remark. It is implied that the craftsman has assimilated all practical knowledge of his art, that he has little to learn in the way of technique, but that there is a laboured look and a lack of spontaneity about his work. There is a hackneyed expression, "art that conceals art," and I can think of no better one to indicate what I am trying to get at. It is quite impossible for you to know too much of posing, of turning, tilting, and foreshortening head and limbs, and of the suitability of certain positions for certain types—but (and it is a very big " but ") if you merely regard the physical form of your client, and out of your empirical knowledge select a pose, and take the portrait accordingly, it is likely that the result will be a very good piece of work, *yet it may have artificiality stamped all over it.*

To cut it short, George, if you would be an artist in this business, you must know how to *make the sitters pose themselves.*

Now, just keep in mind what I have been saying, keep behind the camera all the time I am taking the first plate, focus and slip me the ball as smartly as possible. Well, why don't you get the camera approximately to the focus? You know it is to be a three-quarter length, and the last sitter was a baby on the floor! When you have a good idea of the style of picture you contemplate, don't for goodness' sake leave all the necessary mechanical camera operations until the sitter feels the position stale and becomes fidgetty. Scarcely a second should elapse between setting up the model to your satisfaction and the making of the exposure.

Ah, there you are, Miss Miller, we are just ready for you. No, no, don't take off your hat—at least, not yet. Oh, just keep your hand as you have it on the brim of your panama, only turn the wrist a little away; that's it, I get a side view of your hand now, and in addition we feature your wristlet watch. I would like you to stand over here a little, however; ah, that's right, that'll do splendidly. You've got your left hand splendidly placed, playing with those beads, but if you just extend the forefinger a—that's it, that's it. Now, Mabel, let your head incline a trifle more towards the hand on your hat. Did ever you hear the expression " the glad eye "? Good girl, I've got you. Yes, it's really done. I'm getting quite smart now that I have an energetic assistant to push me on. Now, run away and see that you do your hair very tricky, we want to do something special of you without your hat.

While Miss Miller is in the dressing-room, George, we will go over my procedure with that negative which has just been exposed. As you know, I have the entrance to the studio so cunningly contrived that the victims walk right into the line of fire. It is unnecessary to say " Stand down there, please," or " Would you mind taking a seat over in this corner?" Even with a sitter on whom you are prepared to use a few plates, the first one exposed is very frequently the best. Of course, I had our model of to-day weighed up long ago. Miss Miller is what sour faced people call a " flapper." Her pretty clothes, her high heeled shoes, her bracelets and beads are looked at askance by those who love neither beauty nor youth. The flapper has brought joy and colour into our lives, and certainly deserves well of the photographer. But let us photograph her to *look* like a flapper, not like a policeman at point duty. Miss Miller herself gave me a pose. I would naturally want to show all I could of her jumper, and as both hands are bejewelled, the rings and bracelets are put there to be seen, so we have to feature them well. What more simple than the one hand on the hat and the other (a totally different view of a hand) toying with her beads? When we were photographing Joe the other day I wouldn't let you shift him, but insisted that you move the camera instead. Why then did I ask Miss Miller to move? Just because she was standing on the wrong foot. Even though the picture is only a three-quarter length, the head tilted forward and the body resting on the " hind " leg would show unmistakably that the pose was just a pose, and that the photographer was fumbling ignorantly. Many of the present styles in women's dress are evidently designed to conceal the figure, and if we are not careful, very ugly results may occur. Study fashion plates and pictures of well-known beauties and you will see that the artists are all careful to make their models lean well forward, by this means getting the maximum of action and grace into the figure. If it cannot be said that a three-quarter length is merely a bust plus body and arms, certainly it can be termed a full length minus feet.

I made Miss Miller turn one hand slightly. Take a mental

note of this tip, George:—Photograph hands side face and feet front face if you wish to make them appear smaller. Sounds very funny, doesn't it? That's just why it ought to stick in your mind, and I make no extra charge for the memory course. Some day we will do nothing else but hands and feet, but meantime that will do to be going on with.

You saw me manœuvring the blinds. The lighting which would have done for an ordinary standing figure was too high for a broad-brimmed hat. An ugly shadow was just on the eyes (exactly what the hat is for, of course), so to avoid tilting the head up too much I let in a patch of low front light. A painter may get a wonderful effect with the eyes looking out of shadow, but I have never seen it done successfully in a photograph. You know the good old rule of exposing for the shadows. Carry it out to get the under part of the hat fully exposed, and the rest of your picture would lose its brilliancy. Whatever your scheme of lighting, be most particular about the eyes. One eye looking through a shadow has the effect in a photograph of making a great difference to the likeness.

I made rather a short exposure, and for two reasons. Firstly, I'd sooner have a little under-exposure and get a happy expression and a steady negative. Secondly, I want the picture to be bright and certainly not a fraction over-exposed. That's a point I haven't touched on yet, the influence of exposure on to the tonal quality of the composition. In our first lesson, I suggested that you might with advantage slightly exaggerate contrast in lighting to atone for the loss in brilliancy suffered by coloured objects represented in the drab medium of a photograph. We have now a concrete example of this necessity in the portrait of our typist. White panama hat, lemon-coloured jumper, crimson beads, and skirt of an uproarious check do not humbly ask to be rendered in low key. We frequently hear scathing remarks from fuzzographers about "soot and whitewash" productions. That's a grand expression, George, to hit off the picture lacking in half-tones, but, as Lord Bacon said, "there is a superstition in avoiding superstition," and a portrait in the "mist and mud-bath" style (invariably in folder of "art" paper) is the opposite extreme of the dud worker. Of two evils, the public will choose "soot and whitewash" every time, for greyness and over-exposure can only masquerade as "softness" to a photographer already in the soft and grey stage himself. Mental note, George:—Only accurate exposure can give you a negative faithfully rendering what you worked in the studio; under-exposure intensifies contrast; over-exposure does the reverse. The merest beginner may know that, but few old hands appreciate the full significance of the modifying effect on the scheme of lighting. Yet many exceptionally clever photographers habitually depart from what would ordinarily be the right exposure, and are amply justified by the results they produce. That, however, is a matter for the consideration of experts. I have no prejudice against soft-focus work, the use of under-exposure in getting rid of unnecessary detail, or any other departure from the straight path of text-book exactitude, but I believe most firmly that until the young student is strong enough on the technical side to produce straight negatives faithfully giving us what the eye saw in the studio, he is not strong enough to take liberties, and to attempt something startling in portraiture.

Let us now go back a little. I said the brim of Miss Miller's hat threw a heavy shadow on her brow and eyes. Well, to have exposed for that shadow would have lowered the tone of the hat, impaired the glow of the bright jumper, and given us, instead of a picture of the holiday girl, a negative that O. Henry might have described as "flat, stale, and unprintable." So I softened away the shadow—flappers don't like shadows—and exposed for the merry and bright.

Now here is our sitter again. Ah, bon jour, Suzanne. You know who Suzanne is, don't you, George? No? Well, you do surprise me. I begin to think it is you who are the old fossil, not me. I often wonder what you young fellows do with your time. A portrait photographer should be as up-to-date as a journalist. Miss Miller knows quite well what I mean, and is rather flattered that I take notice of her style in hairdressing. If you don't know anything about ladies' dress and fashions, George, you can never hope to score as a portrait maker for the fashionable set. Bring mo up the tennis racquet, my lad. Thanks, now show us the Lenglen leap, Mabel. Well, after all, we'll have to do something more subdued, we can't do moving pictures yet. Never, never get into the way of inflicting positions on sitters, or, as I ought to say to be accurate, get out of the bad habit. Make the punishment fit the crime, or, to be quite literal, suit the position to the age, the temperament, the dress, and the immediate mood of the client. That's rather a good idea of the great photographer of men, to find out for what purpose the picture was required, my only objection being that Mr. Macdonald says he *asks* the client. That's most reprehensible, and can only be excused by the fact that constant contact with the sterner sex has rather blunted the artist's finer perceptions. Think whether a certain position is meant to suggest movement or repose. Connect your accessories with the suggestion, and endeavour to express something with every picture. Upon my soul, I am beginning to have sympathy with that literary bore who writes long articles, every line of which begins with "Don't." Unfortunately there is so much to unlearn, that the don'ts are imperative to one who, like Hamlet, was born to set things right. Now, don't mix up the elements of movement with suggestions of repose. A girl in summery attire, with a tennis racquet, does not require a balustrade to prop her up. You can't take her actually in action, for that can only be done satisfactorily out of doors, but you certainly must do nothing that will detract from the suggestion of action. To get the right swinging movement into the body, watch the feet, of course. Yes, in those positions there is always more risk of the sitter moving, but a spoilt plate now and again is better than the Doan's backache portraiture. I think I can show you, however, how to reduce the risk of moves to a minimum. Always get the *extreme* of movement into your subject, with the feet properly placed. Do this yourself (when nobody is looking) in all the different placings of the feet, pressing rather too much where the weight is resting, and you will find that there is a kind of automatic lock steadying up the figure. With an incomplete movement, there is always uncertainty, and the danger of oscillation. One cannot go farther than the extreme.

Anything that keeps the hands well occupied is a great help in composition. Don't let both hands grasp the racquet or stick so that two sets of knuckles and fingers are featured as bunches of sausages or bananas. The beauty of a hand is, like the charm of Cleopatra, infinite variety. Regard the fingers as separate entities, and think of their interdependence. Don't laugh at my flowery language, George. I want you to get it rooted in your mind, just as I wish you to have a meaning for everything you do, that behind my funniosities there is always a serious lesson. One of my cleverest pupils once had a good joke at my expense. He took an elaborate picture of the message boy, and called it "The interdependence of the fingers." The joke lay in the fact that the boy's thumb was pressed to his nose. After all, it wasn't a bad illustration, and we may as well get a bit of fun out of our business as we go along. I want you, George, to make a practice of studying the work of advertisement and poster artists. There is a beautiful picture appearing just now on the hoardings, advertising a soap, a study of a young woman with a golf club. Spend a few minutes before that picture, George, and study the treatment of the hands.

Now, Miss Miller, you'll be getting weary of all this talk, we don't give a lecture with every client. Just hold the racquet as if you were resting from your exertions on the court. You see what I mean, George, about the hands. Comfort and beauty don't necessarily go together. Although Miss Miller is holding the racquet easy enough, it isn't right for

pictorial effect. Here's a thing I want to draw your attention to. Avoid angularity: the right arm there is too close to the body, and the loose-fitting sleeve runs into the figure giving a spurious stoutness which is seldom appreciated. Make the arm move from the shoulder, not from the elbow as if the upper part was paralysed. See what a difference that widening out has made, and how easily the hands have been altered. I have got a very diffused light on now, as you see, but I am not finished with the scheme. This is a great subject for a bit of jazz lighting. Just watch while I light up the hair, and cut out the figure a bit with the spot light. That's pretty good, I think; we'll expose it at that.

I seem to have done an extra amount of talking this morning, and I don't feel inclined to give you much more to ponder over. I was pleased to see that you have started a scrap book on the lines I suggested, and I can say that I was delighted to read your comments. You can't have too much material for this study work. A good plan is to collect the items as they appeal to you, sketches out of papers, illustrations of fashions, unmounted photo scraps, etc., and make the classification later. Some evening I'll take a heap of this stuff, and we'll go over it critically, and do some reconstructing. Thank you, Miss Miller, good morning, George.

J. Effel.

THEORY AND PRACTICE OF DEPTH OF FOCUS.

V.

[In the present chapter the student of depth of focus is introduced to the very ingenious optical conception of Dr. M. von Rohr, viz., the "plane focussed for," by which the formulæ for depth calculations are obtained in a much simpler form. Such formulæ are based on the view, which may be held in almost all cases, that the print is viewed under an angle of vision corresponding with that which prevailed in the taking of the negative. Before the chapters on the theory of depth of focus reach their conclusion acknowledgment should be made of the help rendered in their compilation by a contributor to the "British Journal," the Rev. H. C. Browne, of Dublin. We happened to mention to Mr. Browne that the present series of articles was in preparation and subsequently were exceedingly grateful for his reading of proofs and for a number of suggestions by which the subject was presented somewhat more exactly and clearly than would have been the case in the absence of his assistance.]

In the preceding chapters the question of depth has been treated chiefly from the standpoint of adopting a certain diameter of disc of confusion in prints without regard to their size, and thus with neglect of the phenomena of vision outlined in Chapter I. In accordance with this view, the formulæ relating to depth have been obtained from construction in the image space, that is between the lens and the focal plane.

But, as shown in Chapter I., there is reason for adopting a variable diameter of the disc of confusion, permitting the latter to be larger or smaller according to the greater or lesser distance from which the print

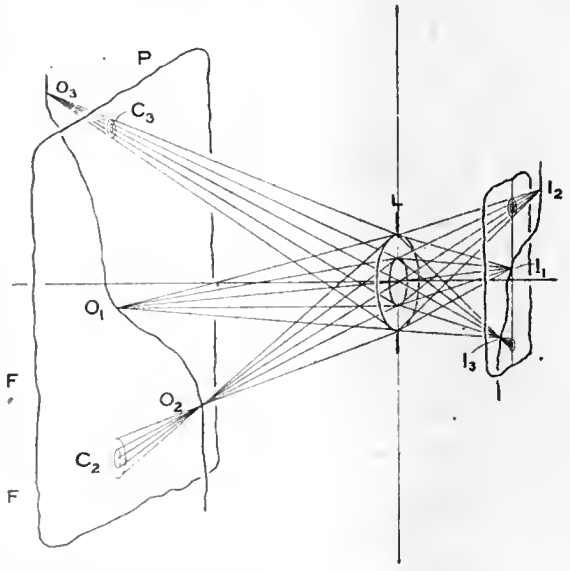

Fig. 8.—Illustrating the Von Rohr "plane focussed for." The image on the focussing screen is assumed to be projected on the imaginary plane, *P F F*, containing the part O_1 of the object which is in sharp focus.

or enlargement is viewed. This principle appears first to have been recognised by Mr. H. Dennis Taylor ("Photographic Quarterly," April, 1890, pp. 267–282) and was actively propagated by Mr. W. E. Debenham in the course of press controversies on depth of focus. But we owe to Dr. M. von Rohr [1] a most ingenious optical conception by which the consideration of depth (from the standpoint of a variable disc of confusion) is greatly simplified. The basis of this conception is the "plane focussed for" (Einstellungebene), the meaning and use of which must first be explained.

In fig. 8, let O_3, O_1, O_2 represent an object parts of which are at different distances from the lens *L*. The latter, so far as the transmission of image-forming pencils is concerned, may here be represented for simplicity by a single diaphragm of diameter *d* instead of by the pair of pupils (entrance and exit) necessary for the complete representation of its action. Suppose that the lens is focussed on the point O_1, a point image I_1 being formed on the focussing screen or plate. Plainly at this setting for focus the image of the nearer point, O_2, is formed at I_2 behind the focussing screen, and that of the further point O_3 at I_3 in front of the focussing screen. In other words, an aerial relief image is formed of the object extending in space on each side of the focussing screen. On the screen the points O_2 and O_3 are recorded as discs, which are the cross-sections, in the plane of the screen, of the pencils transmitted by the lens from these two points.

Let it be now imagined that we erect a semi-transparent screen passing through the point O_1 which was focussed and, like the focussing screen, placed perpendicularly to the lens axis. This, *P F F*, is von Rohr's "plane focussed for." Its purpose is to serve as a plane rendering of the solid (spatial) object and thus to permit of the out-of-focus phenomena being treated in the object instead of the image space. Fig. 8 illustrates approximately to scale its application in this manner. The image on the focussing screen is supposed to be projected on to the *P F F* so that the disc of confusion representing O_2 is obtained as the larger disc C_2 and that representing O_3 on the focussing screen as the disc C_3.

Plainly, the sizes of these imaginary discs in the *P F F* are determined by the scale of reproduction given by the lens according to its focal length and the distance of O_1 from the diaphragm. Hence if the disc of confusion (representing O_2 in the print) is imperceptible when viewing the print from the position of the diaphragm (which is the proper viewing distance for perspective rendering), the disc C_2 in the imaginary plane projection of the subject will also be imperceptible when viewed from the diaphragm. *Vice versa*, if these imaginary discs of confusion in the projection of the image on the *P F F* are imperceptible when viewed from the diaphragm, the reproductions of them in the print will be imperceptible when the print is examined at its correct viewing distance.

From fig. 8 it is clear that it is easy to obtain geometrically the diameters of the confusion discs (in the *P F F*) which correspond with an object point at any distance, simply by drawing the bounding rays of

[1] *Zur Geschichte und Theorie des Photographischen Teleobjectiv* (Weimar 1897); also *Eder's Jahrbuch* 1906, pp. 62–66.

the pencil (from the point) which pass through the diaphragm; producing them to meet the *P F F* in the case of nearer objects, *e.g.*, O_2. In this construction we have a simple means of providing the geometrical data for the application of the rules of sharpness of vision without requiring to know anything about the image or the focal length of the lens. The device of the *P F F*, so to speak, abolishes the image side of the optical system, so far as the derivation of depth rules and formulæ is concerned. Nevertheless the lack of accommodation of the eye in respect to viewing points which should be looked at nearer than 10 or 12 inches is a fact which cannot be ignored in depth computations according to the system now under consideration.

Before proceeding to show how these formulæ are derived, it must be pointed out that the present system does not reduce depth rules to such rigid forms that there is not the occasion for judgment as regards the permissible degree of definition. Far from it. Although it is no longer a question of choosing between a circle of confusion of say 1-100th or 1-250th of an inch, there is a precisely similar latitude offered as regards the value which shall be adopted for the angle of sharpness of vision. As already shown in Chapter I. an angle of 1′ (= 1-3438th) represents the most critical standard of definition, but it is generally considered that an angle of about 1′ 42″ (= 1-2000th) is sufficiently small; and even one of about 3′ 26″ (= 1-1000th) is regarded as not too large for much photographic work in which a critical standard of definition is not demanded. The use of these various values will be clear from what follows.

Hyperfocal Distance.

Hyperfocal distance has already been defined as the distance of the nearest object obtained in permissibly sharp "focus" when an object at an infinite distance is focussed sharply. In terms of the angle of sharpness of vision, this may be derived as shown in fig. 9. Here we

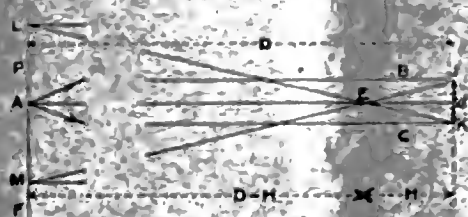

Fig. 9.—Illustrating formula for hyperfocal distance in terms of angle of sharpness of vision.

must be content with showing the assumed infinitely distant point *A* as at a very great distance *D* from the lens diaphragm of diameter *d*. The "plane focussed on" is thus *P F*. The parallel pencil of rays *B C* which passes through the diaphragm thus has its apex at *A*. If the distance from *E* to the diaphragm is taken as the hyperfocal distance (= *H*), the projection of the object point *E* on the *P F F* will be a disc of diameter *L M*. *L M E* and *K E J* are, therefore, similar triangles, whence

$$\frac{A E}{H} = \frac{L M}{J K}, \qquad \frac{H}{A E} = \frac{J K}{L M}.$$

Now $A E = D - H$, $J K = d$, and *L M*, in accordance with the facts of sharpness of vision, must be taken to be, say, 1-2000th of *D*.[1]

Hence $$\frac{H}{D-H} = \frac{d}{D/2000} = \frac{2000\,d}{D}$$

In this process we have assumed *D* to be a very great distance. The greater it is, the smaller is the difference between *D* and *D* − *H*. If *D* is infinitely great as required by our theorem, *D* − *H* becomes equal to *D*, so that *H* = 2000 *d*; that is to say, the hyperfocal distance is equal to 2,000 times the actual diameter of the lens diaphragm, adopting a value of 1-2000th (= .0005) for the angle of sharpness of vision. (Compare formula 4c in Chapter II.)

Distance of Sharp Focus when obtaining Infinity in "Focus."

In fig. 10 *P F F* is the "plane focussed on" at such at a distance *H* from the diaphragm that the projection on it of a point at infinity is of the permissible diameter. Obviously at any finite distance of the *P F F* the pencil from an infinitely distant point which just passes through the diaphragm is itself of the same diameter (*A B* = *d*) as the diaphragm. Hence, when adopting an angle of sharpness of vision of 1-2000, *H* is again equal to 2000 *d*, a formula which is in accordance with formula 5*b*.

Distance of Nearest "Focus" when obtaining Equal "Focus" at Infinity.

Fig. 10 likewise shows very plainly that when focussing on the hyperfocal distance the nearest point obtained in permissible "focus" is exactly half-way towards the lens.

For let *E* be a point on the lens axis such that the projection (on the *P F F*) of the pencil of rays which just passes through the diaphragm

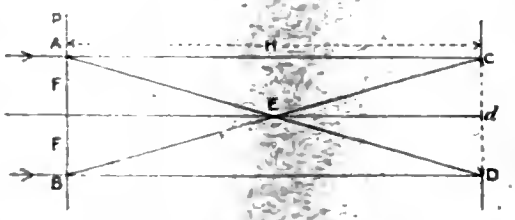

Fig. 10.—In terms of angle of sharpness of vision distance of sharp focus when obtaining infinity in "focus" is the same as the distance of the nearest object in "focus" when focussing on infinity.

is also *A B*. It is almost self-evident that *E* is at a distance *H*/2 (half the hyperfocal distance) from the diaphragm, *e.g.*, 1000 *d*.

It will be observed how very simple is the derivation of these formulæ in the object space compared with that in the image space already investigated in Chapter II.

It follows also that the stop (actual effective diameter) required for a given hyperfocal distance is calculated by dividing the distance by 2,000 or other denominator of the fraction representing the circular measure of the chosen angle of sharpness of vision.

Near and Far Distances to which Depth Extends when Focussing on a Given Distance.

The device of the "plane focussed for" likewise greatly simplifies the derivation of the formulæ for these distances.

In fig. 11, let *P F F* be the "plane focussed on" at a distance *u* from the lens diaphragm *B D* of diameter *d*.

Near Distance.

Let *N* be a point at the axial distance u_1 from the diaphragm. The projection of the image of *N* on to the *P F F* is, therefore, of the diameter *A C*.

From the figure

$$\frac{A C}{d} = \frac{N E}{G N} = \frac{u - u_1}{u_1}$$

Choosing an angle of sharpness of vision of 1-2000th, *A C* requires to be $\frac{u}{2000}$

Therefore $$\frac{u - u_1}{u_1} = \frac{u}{2000\,d}$$

whence $$u_1 = \frac{2000\,d\,u}{2000\,d + u}$$

In words, *the distance from the camera to which near depth extends when focussing on a distance* u *is* 2000 *times the diameter of the stop multiplied by the distance* u *and divided by the sum of* u *and* 2000 *times the stop diameter (for angle of sharpness of vision of* 1-2000).

Since 2000 *d* is the hyperfocal distance, the above formula becomes

$$u_1 = \frac{H \times u}{H + u}$$

corresponding with 8*a* obtained in Chapter III. by construction in the image space.

Far Distance.

Let *F* be a point at such a distance u_2 that the projection of its image on to the *P F F* is a disc of diameter equal to that of the projection of the image of *N*. Then from the figure

$$\frac{A C}{d} = \frac{u_2 - u}{u_2}$$

[1] In this and succeeding diagrams, it is obviously impossible to represent confusion discs in the *P F F*, and distances of the latter from the diaphragm on a scale correctly representing the very small angles of sharpness of vision. In fact, for the sake of clearness, the angles are deliberately exaggerated.

Again, taking $A\,C$ as equal to $\frac{u}{2000}$

$$\frac{u_2 - u}{u_2} = \frac{u}{2000\,d}$$

whence

$$u_2 = \frac{2000\,d\,u}{2000\,d - u}$$

or, writing H instead of $2000\,d$,

$$u_2 = \frac{H\,u}{H - u}$$

The Point to Focus on.

Fig. 11 may be used for the derivation of the formula of the distance on which to focus in order to obtain the best distribution of definition in front and behind the point focussed on.

Let F and N be points at the two distances which are required of equal definition. Draw the bounding rays $F\,B$ and $F\,D$ and $N\,B$ and

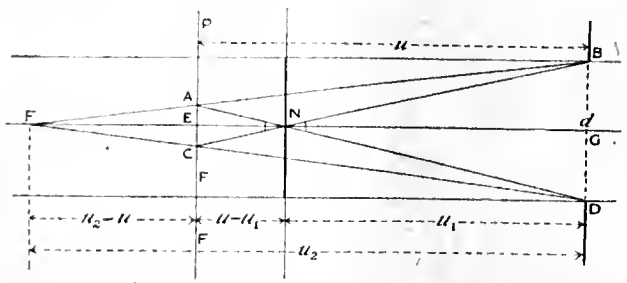

Fig. 11.—Illustrating formulæ (in terms of angle of sharpness of vision) for distances of near and far objects which are in "focus" when focussing on a given distance.

$N\,D$ of the pencils from each to the diaphragm and produce those from N to meet those from F in A and c. The distance $E\,G = u$ is then the required distance no matter what value is taken for the angle of sharpness of vision.

From the figure

$$\frac{A\,C}{d} = \frac{u_2 - u}{u_2}$$

and

$$\frac{A\,C}{d} = \frac{u - u_1}{u_1}$$

Therefore

$$\frac{u_2 - u}{u_2} = \frac{u - u_1}{u_1}$$

whence

$$u = \frac{2\,u_1\,u_2}{u_1 + u_2}$$

This formula is naturally identical with No. 15 in Chapter IV., since no standard of permissible unsharpness is involved.

G. E. B.

TECHNIQUE—AND THE D. & P. SLUMP.

"Slump" is not a nice word to use in connection with business, but unfortunately it is the most expressive word for a state of affairs which will persist in making periodical appearances. It expresses the present state of affairs in D. & P. as experienced by many dealers.

The fact that many tradesmen of diverse sorts have become "dealers" during recent years does not fully account for this slump, because they are not the only ones to suffer. At the same time, this dilution of the trade must have had its effect, but I do not consider that any professional man who undertakes D. & P. need worry about the opposition of cycle dealers and boot repairers, or blame such opposition for his declining business. The weather has certainly had a telling effect on this trade, but it has affected some more than others.

This unpleasant situation is being summed up by many dealers—by which term I mean bona-fide dealers, whether purely dealers, pharmacist dealers, or professional or trade photographer dealers—in a fatalistic mood, as a something which could not be foreseen, prevented, avoided or ameliorated. I foresee a number of firms dropping out of the line before next season, believing that it is played out. I foresee further price cutting, though enough of that has been done already. What I am not so sure about is a move to build something better out of this year's disappointment. It can be done. And the professional photographer should be the one to do it.

The slump is not entirely real. Some do not know there is one. I know dealers who have done better this year than ever before. And that in the face of three and four times their previous opposition. And in the same districts as others who know there is a slump. Again, some manufacturing firms have claimed that their immense D. & P. departments are not slack. If that is so, somebody must be doing the business. Why, then, are others thinking of giving up? I believe that it is merely a case of the survival of the fittest, though naturally there may be isolated cases which cannot be placed under this law. It sometimes happens that a well-organised and efficient business goes down before the opposition of a very dubious rival, but these cases are rare, and the general inference is that the successful shop knows or does something that the other does not.

When times are threatening, a certain type of business mind can think of only two things, namely, reduction of expenditure and reduction of charges. This has been the case with D. & P., and consequently there has been some very cheap-looking work about. But cheap-looking work does not appeal at these times. It may pass muster in the rush of a busy summer trade, and I have known poor stuff to be turned out and accepted in so many hours at seaside places. Cheap-looking work, however, is not acceptable even to the much-criticised British public at ordinary times, and it cannot build a reputation, even to the extent of one small repeat order.

What is the alternative to price-cutting and developing without charge? The alternative practised by the dealers I know who have not felt the slump is to keep up the prices and turn out better work. Also to keep a time table that was within possibility. As there have been no excessive record rushes of work following glorious week-ends (due to the absence of the glorious), it has been easy to keep things straight, but whereas the same cause has left many other dealers with nothing to do from about Wednesday to Monday, the successful ones have been kept going with repeat printing orders and enlarging.

Some have thought that the usual type of print turned out for amateurs was too stereotyped for alteration or improvement. But this is not so. There is perhaps nothing else in the whole craft which is so open to change. What is the usual thing? With a first-class dealer it is a thin gaslight print, of decent quality, though perhaps a trifle hard, fairly good as to quality of black, and masked with a clean narrow white border. With a good many others it is the same thing in a poorer quality and nondescript colour, unmasked or masked with a broken mask, and probably untrimmed. The surface in either case is semi-matt or glossy. Possibilities for change and improvement bristle all around this standard. Why gaslight? some may ask. On account of the great vigour which is necessary for amateur "negatives." But some firms make bromide paper that will cover the flattest negative that could remain outside the dustbin. Bromide saves light, and gives purer blacks with ease, though I do not wish to advocate any system of working in sepulchral shade. Extra contrasty bromides do not need semi-darkness, though they expose more rapidly than gaslights. Why thin paper? Have you ever seen a thin print which had lain in a client's pocket or wallet for a month or two? Mounted or card prints are worth any price in comparison. Why black and white? We don't like toning, admittedly, but it may be worth it. Why a white mask? I remember a time when midget portraits with similar masks were common. Then someone started black masking, and the system became popular.

I could go on with similar questions and answers, but I have gone far enough to express my ideas of the endless possibilities of a photographic line which, instead of being played out, is yet in its infancy. Someone will give their attention to this subject and secure the major portion of what trade there is, so that, slump or no slump, they will have something. There is every reason that this should be done by professionals. They have the knowledge and experience which is wanting with some of their opponents. Not so long ago many of them were looking none too pleasantly at the chemists and druggists for handling D. & P., though the latter have only acquired this trade by filling a public need when nobody else would bother. Now is the time for the professionals who are interested to make their claims for better and more profitable photography for amateurs and happy snapshotters.—THERMIT.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

Report of Council.

On Thursday, March 28, 1901, in the Chapter Room of Anderton's Hotel, Fleet Street, under the chairmanship of Thomas Bedding, was held the first meeting of professional photographers who afterwards formed the Professional Photographers' Association. The Council are pleased to report that several who were at that first meeting are still members, and take an active interest in the work of the P.P.A.

The President and Council offer to all concerned the heartiest congratulations on the P.P.A. having attained its twenty-first birthday, and in honour of the event have organised a Congress of professional photographers, which it is hoped will increase the fraternal goodwill between all sections of the profession and advance the interests of its members. The Council regret that for several reasons the Congress could not be held on the date of the annual general meeting; but, in order to give the members an opportunity of attending both, adjourned the latter until the last day of the Congress.

The Assistants' Evening is a new departure at the Congress, which it is hoped will meet with the approval of all; the Council are of opinion that on an occasion like the present the assistants should in some measure share in the advantages of the Association.

The incorporation of the Association is an important event which coincides with its coming of age, and the Council feel that under the guardianship of the Board of Trade the interests of the members will be fully safeguarded and its officers protected. The whole of the incorporation expenses have been paid, and thanks are due to Mr. Vaughan, the hon. solicitor, for his valuable assistance.

The balance-sheet and statement of accounts were presented at the first part of the annual general meeting, on March 10, and the financial progress since then is satisfactory.

The membership continues to increase; we have lost a few by death, resignation, or retiring from business and other causes. A small number have neglected to fill in their incorporation form, and therefore cannot be counted as members until they do so.

At the invitation of the Master Photographers' Association of Lancashire, Mr. A. Swan Watson, the President, and the Secretary, attended the annual Conference at Blackpool, where they were most heartily welcomed and entertained; Mr. Lang Sims was invited earlier in the year to Manchester, and these visits have undoubtedly brought about a closer friendship with our country brethren. Honorary membership has been arranged with several kindred associations, and to any of their members visiting the Congress a very hearty welcome will be extended.

The Propaganda Committee have done good work in making the Association known to photographers, and in producing "The Record," a journal which it is hoped will not only be an efficient means of communication between the Council and its members, but of sufficient interest to induce every professional photographer to join the Association.

The question of electric current at power rate is still receiving the attention of the Council, and the recent legal action, lost by a photographer who was not satisfied with the concession obtained by the P.P.A., serves to show that the Council were well advised to adopt peaceful persuasion instead of litigation.

Several cases of copyright have been satisfactorily settled without legal proceedings, although the assistance of the hon. solicitor has been invoked on a few occasions.

Thanks to Mr. Gray, a member of the Council, an authoritative statement has been obtained through the Great Western Railway Company that the railway companies now agree that professional photographers can carry their apparatus as personal luggage up to 100 lbs. free when travelling third class.

The usefulness of the Association to its members is exemplified by the help and advice given on the following subjects:—Studio building; defective postcards; legal help to Irish member; rates of wages; Sunday trading; taking views for local paper; ownership of negatives; Press reproduction fees for country papers; County Court summons; photographers' advertisement; charges for outdoor work; defective dry plates; purchasing businesses; failure to supply goods; Income Tax; Rent Act; taking estate photographs for advertisements; goods damaged by rail; goods damaged by post; newspapers reproducing single portraits from groups; charges for work away from the studio, etc., etc.

The Council have to report the resignation of Mr. Lang Sims, as secretary, on the inauguration of the Incorporated Association, and the appointment of Mr. Alfred Ellis, who is devoting the whole of his time to the work of the Association. Mr. Alexander Corbett has been elected chairman of Council in place of Mr. Ellis.

The thanks of the Association are due to the Royal Photographic Society for the use of their house for the Council meetings, to the Editors of the "British Journal of Photography," "The Kodak Professional Photographer," "Houghton's Bulletin," "The Photographic Dealer," and the "Amateur Photographer" for publishing reports and notices of the work of the Association.

THE P.P.A. CONGRESS.

Next Week's Programme.

Headquarters.—Prince's Galleries, Piccadilly, a few yards from Piccadilly Circus, and nearly opposite the Royal Academy.

Monday, September 11.

11 a.m.—Informal opening for registration of members, etc.

12 (noon).—Official opening of the Exhibition by the Right Hon. the Earl of Carnarvon.

7 p.m.—Reception by the President and Council.

8 p.m.—Presidential Address by Mr. A. Swan Watson on "Some European Portrait Painters, and Some Teudencies in Modern Portraiture by Photography."

Tuesday, September 12.

10 a.m.—Visit to the National Gallery, Trafalgar Square. Members will be conducted round the galleries by Mr. Hubert Wellington, who will deliver a special lecture. Members will also visit the National Portrait Gallery. Ticket for these two visits, 1s.

1 p.m.—Luncheon at the Adelaide Galleries of Messrs. Gatti, 436, Strand, nearly opposite Charing Cross South-Eastern station. Ticket, 4s.

3.30 p.m.—Lectures by Mr. C. P. Crowther on "The Man Behind the Camera" and "The Making of Portraits."

8 p.m.—Lecture by Mr. Charles Aylett, of Toronto, on "Unusual Portraiture," including spot lighting and soft focus.

Wednesday, September 13.

9.30 a.m.—11.30 a.m.—Visits to London studios by previous arrangement with the Secretary.

10 a.m.—1 p.m.—Demonstrations of apparatus, etc., by manufacturers and dealers.

3 p.m.—Lectures by Mr. Herbert Lambert, of Bath, on "Should Brother Photographers be at Daggers Drawn?" and Mr. Frank Brown, on "Photographic Parasites."

8 p.m.—Lecture by Mr. Pirie Macdonald, of New York.

Thursday, September 14.

9.30 a.m.—Departure by char-a-banc from Prince's Galleries to Windsor.

11 a.m.—Visit to State Apartments and Grounds of Windsor Castle.

12 (noon).—Congress Group on the East Terrace will be photographed by Mr. W. B. Chaplin (J. Russell & Sons, Windsor).

12.45 p.m.—Luncheon at the Royal Albert Institute, Sheet Street, Windsor.

2 p.m.—Departure from landing stage, Barry Avenue, River Street, by "Empress of India," for Staines.

4 p.m.—Departure from Staines by char-a-banc, reaching London at 5.30.

Tickets for this excursion, price 15s. each, must be ordered from the Secretary not later than Monday evening, September 11.

6 p.m.—Assistants' evening. Reception by the President and Council.

8 p.m.—Address by Mr. George Hana on "Assistants as Associate Members."

9 p.m.—"A Talk on the Exhibition of Pictures," by Mr. Marcus Adams

Friday, September 15.

10.30 a.m.—12.30.—Visit, by invitation, to the Photographic Salon, 5a, Pall Mall East, a few steps westward from the National Gallery.

3 p.m.—Annual General Meeting.

4—4.30 p.m.—Discussion on Co-operative Advertising of Photographic Portraiture.

6.30 p.m.—Reception by the President and Mrs. Swan Watson.

7 p.m.—The Congress Dinner. Tickets, 10s. 6d. each, from the Secretary.

Saturday, September 16.

11 a.m.—Advance private view, by invitation, of the Exhibition of the Royal Photographic Society at 35, Russell Square, W.C.1, within a few steps of the north-east corner of the British Museum.

Where not otherwise stated, all meetings take place at the Headquarters, Prince's Galleries, Piccadilly.

The exhibition of portrait, pictorial and technical photography, and also that of the photographic trade, will be open daily to the public from 10 a.m. to 9 p.m., except on Monday, from 2 to 9 p.m. On Thursday the gallery will be open to the public from 10 a.m. to 5 p.m. Charge for admission, 1s.

FORTHCOMING EXHIBITIONS.

August 26 to September 9.—Toronto Camera Club. Secretary, J. H. Mackay, Toronto Camera Club, 2, Gould Street, Toronto, Canada.

September 9 to October 7.—London Salon of Photography. Particulars from the Hon. Secretary, London Salon of Photography, 5a, Pall Mall East, London, S.W.1.

September 11 to 15.—Professional Photographers' Association, Prince's Galleries, Piccadilly, London, W. (Trade and Professional). Hon. Secretary, Richard N. Speaight, 157, New Bond Street, London, W.1. Also foreign invitation loan exhibition of professional portraiture. Hon. Secretary, Marcus Adams, 43, Dover Street, London, W.1.

September 18 to October 28.—Royal Photographic Society Annual Exhibition. Particulars from the Secretary, Royal Photographic Society, 35, Russell Square, London, W.C.1.

October 18 to 21.—Rotherham Photographic Society. Latest date for entries October 4. Hon. Secretary, S. G. Liversidge, Orissa, Gerard Road, Rotherham.

October 18 to 28.—Portsmouth Camera Club. Latest dates: Entry forms, October 11; exhibits, October 16. Particulars from the Hon. Secretary, C. C. Davies, 25, Stubbington Avenue, North End, Portsmouth.

1923.

March 2 to 31.—Pittsburgh Salon of Photography. Latest date, February 5. Secretary, Charles K. Archer, 1,412, Carnegie Building, Pittsburgh, Pa., U.S.A.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

Applications, August 21 to 26.

PLATE-HOLDER.—No. 23,082. Photographic plate-holder. F. E. M. Lovell.

PRINTING FRAME.—No. 22,791. Photographic printing frame. L. Crayssac.

CINEMATOGRAPHY.—No. 22,711. Motion picture films. W. van D. Kelley.

STEREO CINEMATOGRAPHY.—No. 23,017. Production of stereo films for cinematograph projection. G. W. Cooper and Stereo Kinema Syndicate, Ltd.

RELIEF CINEMATOGRAPHY.—No. 23,169. Apparatus for producing cinematographic pictures with relief effect. C. Parolini.

COMPLETE SPECIFICATIONS ACCEPTED.

FOCUSSING FOCAL-PLANE CAMERAS.—No 183,492 (September 12, 1921). The invention relates to that type of camera in which the picture is received and focussed on the blind of the focal-plane shutter, which latter, during the focussing operation, is held in a position corresponding with that which the plate will afterwards occupy and is moved forward for the exposure of the plate. The invention consists in means for effecting the usual focussing operation, and the subsequent exposure. The invention is intended for cameras of the type in which a shutter is used to cover the plate, etc., nearly in the focal plane of the optical system, the lens being unobscured save perhaps for a removable cap. A reflex type of camera has been proposed wherein means were provided for bringing the reflecting surface (which was a focal plane shutter) into view, and compensating for error due to the displacement of the focal plane during focussing, the means being interconnected with the shutter release mechanism so as to give a readjustment simultaneously with the shutter-release. The invention it is claimed allows the focussing of the view to be carried out more accurately than heretofore.

According to the invention, a means is provided whereby when the operator focusses the optical system, the focal plane shutter (usually of fabric) which acts as the reflecting surface during focussing is pressed back against the plate or plate holder, so that its reflecting surface lies in the true permanent focal plane of the camera, during the operation of focussing, and

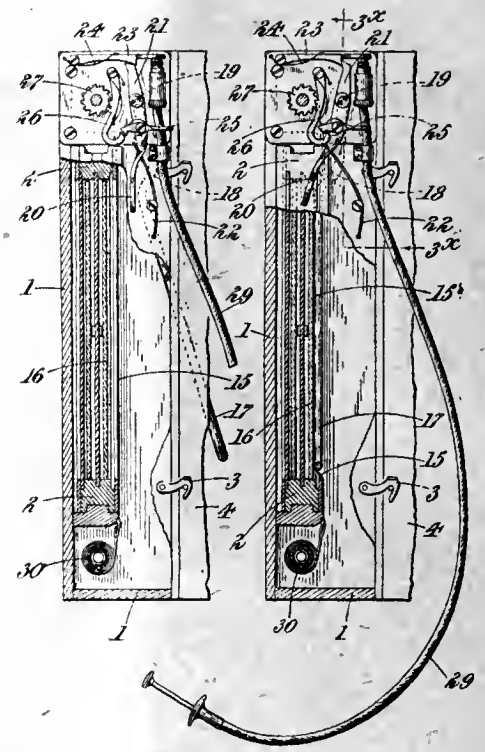

Fig. 1. Fig. 2.

means are provided to prevent the release of the shutter or blind whilst thus under pressure and distortion, the act of releasing the shutter to expose being synchronous with its release from pressure.

In carrying out the invention, for use in conjunction with the preferred embodiment thereof, a spy-hole is provided, normally covered, but uncovered against resilient resistance by the operator, preferably by the pressure of his eyebrows or temple upon a suitable pad. Shaped cushions or a pliable mask or like device may be used to fit closely against the operator's face to exclude light. Through the holes, the operator can then inspect the image formed on the focal plane shutter, which may be of white or light colour in order better to reflect the light.

In the drawings, figs. 1 and 2 show the rear end of the camera in broken section across the axes of the shutter rollers, in the position after the exposure and in that during focussing or prior to exposure. Fig. 3 is an elevation of the rear part of the camera with plate holder and shutter as if seen from the lens of the camera in section on 3x—3x of fig. 2.

The rear part of the camera comprises a shallow rectangular frame 1, fitted with any usual plate carrying device 2. The frame 1 is attached to the body of the camera by clip hooks 3.

The body of the camera comprises a rectangular frame 4 of wood forming a housing for the ordinary bellows when the camera is shut up. A hinged platform (not shown) may provide a support for the bellows and lens carrier when they are extended, and is of ordinary type, closing the camera when shut up.

According to this invention the reflecting surface, being the flexible focal-plane shutter 15, is pressed back against the plate 16 or plate holder by a wire frame 17 which contacts with it around the edges of the reflecting area, leaving a clear space on which to sight. The wire frame 17 is bent as at 18 to afford even pressure on the shutter 17. It is mounted pivotally at 19 in the frame 1 of the apparatus, carrying outside the frame a finger lever 20 provided with an extension 21. The lever works against a spring 22 which tends normally to keep the frame 17 away from the shutter 15. The extension 21 is provided with a catch which engages the trigger 23 which is released by hand pressure, either directly or by bulb or Bowden wire 29 or similar method. A light spring 24 tends to press the trigger into engagement with the extension 21. Mounted on the lever 20 is another small pivoted catch member 25 which engages (when the lever 20 is in operative position as in fig. 2) with the shutter pawl 26 engaging the pinion 27 on roller 28 of the shutter mechanism. The roller 28 is furnished with a kinding-knob, which

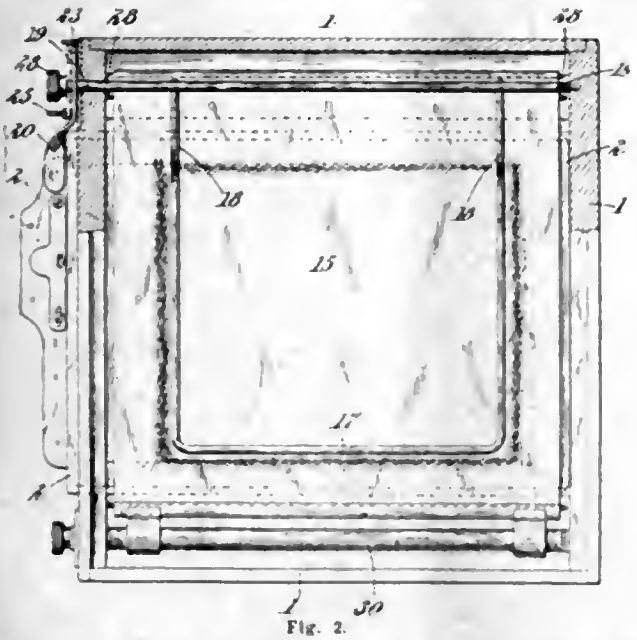

Fig. 2.

may be incorporated with the pinion 27. The bottom roller 30 of the shutter is of ordinary spring-wound type. The reflecting surface of the shutter 15 may be painted white or light colour and may be lined or otherwise marked to show the field as an aid to view-finding. If the plate be resiliently mounted the shutter may be pressed so as to be exactly in the focal plane.

The operation of the device is as follows, the operator winds the shutter up in the usual way, and then presses lever 20 until spring 24 forces trigger 23 in engagement with 21. The frame 17 is now held as shown in fig. 2, pressing shutter 15 against plate 16. In pressing lever 20, catch 25 will engage (under influence of a light spring) with the pawl 26 (also pressed by light spring).

The operator then inspects the image thrown on the shutter 15 through the spy holes provided. When the exposure is to be made, he raises the trigger by the wire device 29, thereby releasing 21, and the frame 17. In flying out, this causes the release of the pawl 26 and the shutter rewinds on to roller 30 as usual. To rewind, the catch 25 is released from the pawl by hand, thus allowing the pawl to operate as usual. It will be observed that the difference between the true focal plane as found by the operator, and the planes of the plate, is only that due to the thickness of the shutter, which is negligible or may easily be allowed for calibration of the focussing device, or be eliminated by resilient plate mounting as above.—Bertram Lewis, 6, Upper Terrace Road, Bournemouth.

Dyeing Photographic Images.—No. 160,137 (March 11, 1921).—The object of the invention is the treatment of a photographic silver image on a plate, film, or paper, in such a manner that it can be dyed with acid or azo dyes, one particular feature of the treatment being that the silver compounds remaining in the treated image are light-insensitive, and do not tend to re-develop when exposed to reducing agents or developers.

The advantage of a bleach which produces non-redevelopable silver compounds is to enable a further printing in the same emulsion without resensitizing after the first image is developed and bleached, without having the silver compounds produced by bleaching the first image re-develop with the development of the second image. In other words, the silver compounds produced by the bleach used are not reducible (to black silver) by a developer, nor will these silver compounds be affected by the light used in printing the second image. That is to say, while a bleach might produce a silver compound which would not be reduced by a developer, if this silver compound were light-sensitive it might then be reduced by a developer, after exposure to light, being changed thereby into the reducible form (printing in the residue of the sensitive emulsion for the second image).

The invention is of special use in the production of long strips of coloured images for motion picture projection, but the invention is also applicable to plates, films, and paper prints of various kinds, whether transparent or opaque. A special application of the invention is in the production of natural colour transparencies, as in motion pictures, wherein each picture area carries several images coloured with complementary colours.

According to the invention, developed silver images are bleached in a bath which transforms the silver into a compound non-redevelopable by a developer and simultaneously deposits on the image a substantially transparent compound of a metal having the capacity of absorbing and fixing an acid or azo dye in proportion to the original density of the image, which is then dyed in acid or azo dyes, with or without removal of the converted silver, the dye being mordanted or fixed only at the places *in situ* with the original silver. A bleaching bath is used for carrying out the process, a bath containing copper or chromium salts, or preferably both; for instance, it has been found that a bath containing potassium bichromate, potassium bromide, copper sulphate and hydrochloric acid gives very good results. The bleach makes the image transparent, even without removal of the non-redevelopable silver salts by hypo, so that the second image can be printed through the first.

The invention provides a process wherein acid and azo colours, such as ponceaus, fast reds, blues and greens, acid fuchsine, and yellows, now used in the wool dyeing industry, can be employed for dyeing photographic images, with the advantages of providing the necessary choice of pure, non-dichroic colours, and complete transparency, fastness, brilliancy and sharpness of coloured image in long lengths of commercial film.

The process starts with a black and white positive, which has been developed, and surplus silver removed by fixing in the usual manner. The coating is then hardened by immersion in a 10 per cent. formaline bath, and washed to remove excess of formaline. This sets the gelatine coating and renders it dye-repellent or tends to prevent it from retaining the dye. The hardening is also important in preventing the gelatine outside the image from taking up the dye. There may be a mechanical absorption of dye in the hardened gelatine, but as it does not fix on the unbleached gelatine it readily washes out in the clearing bath.

The image containing metallic silver is next treated with a bath having the characteristic properties stated, which precipitates or deposits a transparent insoluble mordant *in situ* with the silver, and in exact proportion thereto. This bath also changes the silver to a form which can be dissolved out without affecting the transparent mordant. The action of this bath, it is believed, is to deposit a transparent compound of copper or chromium, or both, or a double transparent compound of copper and chromium, in proportion to the silver, since the image has a brownish colour in reflected light, possibly due to silver oxide, which colour entirely disappears by treatment in the subsequent fixing bath, leaving no silver or silver compound in the residual transparent image. At the same time, the transparent copper or chromium compound is not affected either as to its transparency, or its character as a mordant. It is not known whether the result of the copper chromium bleach is to produce a copper chromium salt which mordants the dye through the reaction with

silver or whether it is a copper chromium gelatine compound, produced through the reaction with silver, which mordants the dye.

The conversion bath comprises potassium bichromate, 4.75 grammes; potassium bromide, 9.5 grammes; copper sulphate, 14 grammes; hydrochloric acid, 10 c.c.; water, 1,000 c.c. Nitric or acetic acid can be used instead of hydrochloric acid. This may be at between 70 deg. F. to 110 deg. F., and only requires a few minutes. The image is then treated in an acid fixing bath to dissolve out the silver compound to give better transparency. This may be done after as well as before the dyeing, without affecting the colouring. After washing for five minutes, the image is ready for dyeing, being now transparent and containing agents capable of fixing acid or azo dyes. The dyed print when washed contains brilliant whites and sharp contrasts probably owing to the treatment having destroyed the normal affinity of the gelatine for acid dyes and the dye only taking in the original image portions.

The dye bath may vary in strength and temperature, but is preferably at about one half per cent. strength at a temperature of from 70 deg. to 130 deg. F. About two minutes' immersion will be sufficient. The working of the dye bath may be sometimes improved by adding 20 c.c. of acetic acid for each gramme of dye. The previous treatments of hardening and conversion have so affected the coating that even a steaming hot dye will not injure the film, nor affect the mordanting and dry absorptive qualities of the transparent copper, or other compounds composing the image. Washing in hot water at from 70 deg. F. to 120 deg. F. for about three minutes will clear the dye from the whites without degrading, or weakening the dyed image, which has the original sharpness, is as transparent as a pure dye image, and has the requisite brilliancy of colouring.

In the above treatment, the gradations of the image are retained so that the dye is absorbed exactly in proportion to the density of the silver. The bleached images absorb dye with or without removing the non-redevelopable silver salts. If the bleached image only absorbed dye after being fixed out in hypo, in making a double (oppposite) coated positive, it would be necessary to fix out the bleached image without touching the unexposed side which would preclude immersion baths. Immersion baths are simplest and cheapest to operate because of less amount of care and time required. This process is particularly advantageous when it is required to obtain two photographic images within one single sensitized coating.

A modification which gives good results is to employ a ½ per cent. solution or sulphurous acid for brightening the colour. This can be put in the dye bath, or used as a dip after the whites have been cleared of dye by washing.

A very satisfactory "two (or more) colour" motion picture transparency can be produced by having one colour, as blue or blue green, made by toning a red family colour value, as with prussian blue in the well-known manner, and another colour, as red or orange, by colouring a green family value by this process, which gives complete transparency, good balancing, etc. These colours may be in one coating on the support, or in separate coatings on the same side of the support, or in coatings on opposite sides of the support, the images on each area in all cases preferably being registered by pins in the printing apparatus with reference to a pre-determined perforation or perforations as a standard. Also, both colours may be produced by this process, or three or more colours, so combined as to render a complete colour on each image area, or additively on successive image areas.—William Van Doren Kelley, 531, Clifton Avenue, Newark, Essex County, New Jersey, U.S.A.
